CALCUTTA

GEOLOGY ON THE ROOF OF THE WORLD

THE ENZO BIO-PROBE™ SYSTEM

- For non-radioactive DNA labeling.
- For rapid detection of specific DNA & RNA sequences in cells following in situ hybridization.
- For rapid detection of DNA on nitrocellulose membranes.
  — Southerns — Colony hybridizations — Dot blots —

Components of the Enzo Bio-Probe System

Nick Translation Kit for biotinylating DNA Probes.
Biotinylated dUTP, DNA Polymerase I, DNase I, Thymidine Triphosphate, Nucleoside Triphosphate Mix, Lambda DNA, Deoxy(8-^{3}H) Adenosine 5′-triphosphate.

Terminal Labeling Kit for end biotinylating DNA Probes.
Terminal Transferase, Terminal Transferase Dilution Buffer, DNase I, DNase I Dilution Buffer, Terminal Labeling Reaction Buffer, Nucleotide Solution, Biotinylated dUTP, Cobalt Chloride, [methyl-^{3}H] Thymidine-5′-Triphosphate, Control DNA.

Detek™ I-*f* for fluorescent detection of biotinylated DNA probes upon in situ hybridization.
IgG fraction goat anti-biotin, FITC rabbit anti-goat, Evans blue.

Detek™ I-*hrp* for colorimetric detection of biotinylated DNA probes upon in situ hybridization and on nitrocellulose membranes.
Streptavidin-biotinylated horseradish peroxidase complex, 10X buffer, Cobalt Chloride.

The Enzo Bio-Probe System is only available from Enzo Biochem.

Pat. Pend.

How to order the Enzo Bio-Probe System

The Enzo Bio-Probe System allows you to nick translate and choose your means of detection, Detek I-*f* (fluorescent) or Detek I-*hrp* (colorimetric). To find out more about the Enzo Bio-Probe System, write-or call us toll-free.

PRODUCT	CATALOGUE NO.	PRICE
Nick Translation Kit		
for labeling 15μg DNA	**EBP-803-15**	$225.00
for labeling 8μg DNA	**EBP-803-8**	130.00
Terminal Labeling Kit		
for end labeling 15μg DNA	**EBP-809-15**	$275.00
for end labeling 8μg DNA	**EBP-809-8**	155.00
Detek I-*f*		
for detecting 200 slides	**EBP-804-2**	$205.00
for detecting 100 slides	**EBP-804-1**	120.00
Detek I-*hrp*		
for detecting 500 slides or 50 Southern transfers	**EBP-820-2** (81 sq cm ea)	$120.00
for detecting 250 slides or 25 Southern transfers	**EBP-820-1** (81 sq cm ea)	75.00
Biotinylated dUTP		
for labeling 15μg DNA	**EBP-806-15**	$175.00
for labeling 8μg DNA	**EBP-806-8**	95.00
Biotinylated dUTP Substrate Mixture		
for end labeling 15μg DNA	**EBP-810-15**	$185.00
for end labeling 8μg DNA	**EBP-810-8**	98.00
IgG Fraction goat-anti-biotin		
for detecting 200 slides	**EBP-807-2**	$150.00
for detecting 100 slides	**EBP-807-1**	90.00
FITC rabbit anti-goat		
for detecting 200 slides	**EBP-808-2**	$ 55.00
for detecting 100 slides	**EBP-808-1**	30.00

NATURE VOL. 307 5 JANUARY 1984

COVER

A freshwater lake in South Tibet, at an altitude of about 5 km. The tripod structure is a floating derrick used for heat-flow measurements. These and other results of a joint French–Chinese study of the North Himalaya–Tibet area are reported on pages 17–36 and in News and Views on page 9.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

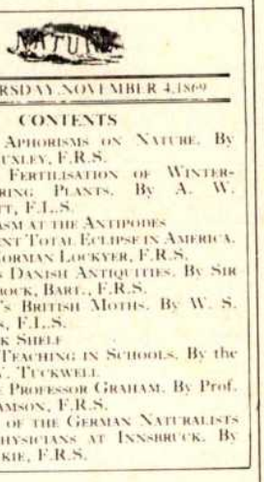
Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.



Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Fascinating reading and an unusual gift

A high-quality, 40-page facsimile of the first issue of **Nature** is now available at the following prices:

UK	**75p**
Rest of World	**US$1.50** (Surface)
Rest of World	**£2.00** (Air)

French at odds on new law

The law to regulate French universities has been signed — and opposing interests are already battling for influence over the decrees that will follow

EXCEPT for a little trouble with the French constitution, which should be resolved next month, France now has a new university law, the first major revision of university law since the student revolution of May 1968. But is the reform too little? Has a great opportunity been lost? The vociferous critics of the new law, notable among them Fields Medallist Laurent Schwartz of the Ecole Polytechnique, say loudly that it has been. Strangely enough, Schwartz's opponent at the ministry of education is another mathematician of similar intellectual temperament: Jean-Jacques Payan, ex-director-general of the principal French research council (CNRS) and ex-president of the University of Grenoble I, one of the foremost scientific universities of France. If Schwartz says the government has fumbled its chance, the man responsible is Payan. But Payan does not think he fumbled the ball but, instead, that he has made a pretty clever pass.

The differences between the two men, which epitomize the arguments over the future of the French university, are based less on differences of outlook than on differences of responsibility. Schwartz is a free spirit, outside the universities and with no power to exercise nor political pressure to which to adjust. Payan is in the hottest seat of all, in charge of the reform and acutely aware of what can and cannot be achieved. The new law is pragmatic, he admits, "but it proscribes little and permits much". Payan urges France to wait for the detailed, non-parliamentary "decree of application" which follows every law. Here may be some of the teeth, some of the support for research that Schwartz demands. "I have the same passion [as Schwartz]: the greatness of the French university", wrote Payan recently. So well do these conflicting passions set each other off than one must wonder whether Schwartz and Payan are in league, one creating the political climate that the other needs.

In reality, there are fundamental differences between the two men and the bodies of opinion they represent. Schwartz and those he speaks for wish to reintroduce selection in the first-year entry to university, the absence of which creates a "catastrophe" for both students and teachers. Payan and the law he represents avoid pre-entry selection and speak of post-entry "evaluation". Entry to the second and subsequent years will, in effect, be selective (as at present) but the word "evaluation" implies more: the universities should not evaluate the students according to some predetermined scheme but according to their students' needs, says Payan. Thus by implication in the new laws, the universities are to turn their resources towards their students, rather than the other way about. This is a revolution: it implies that the universities must become, at least in part, more like the existing technical institutes (IUT) or engineering schools (*grandes écoles*), for the students of the 1980s will certainly demand training that will lead to employment.

What of the dominance of French universities by trade unions and "corporatism"? Elections to various powerful committees of administration and promotion play a great — some say overwhelming — role in the post-1968 French university, and often these elections have been dominated by factional politics, with one union or body of staff against another. Schwartz says the new law worsens the situation. Payan, with some force, argues the reverse and, since he is no syndicalist, the benefit of the doubt must rest with him. According to Payan, the fact that under the new law elections will be by proportional representation, with freedom for non-ascribed candidates, rather than the earlier winner-takes-all system, means that corporatism will be much diminished.

And what of research? Is it ignored by the law, as Schwartz says? Wait for the decree that will define the duties of university lecturers and professors, says Payan. Meanwhile, the text of the law introduces a sabbatical year — a welcome innovation for French scientists. It also establishes periodic evaluation of staff to keep them up to scratch, new recruitment procedures that "will leave little room for the establishment of local cliques" and imposes an obligation of mobility on professors. All this will improve the quality of French university research, says Payan. Moreover, the ministry is turning to a system of research support by multi-annual contracts, rather than the annual support related directly to student numbers presently in force. This should give the universities, traditionally dominated by central government, more academic independence.

As for the decree defining duties, that has been through many drafts and tense negotiations with the unions, and is now again being rewritten. The ministry says that it will take research "much more into account" than previous versions, meeting criticism from the presidents of the universities and others. Payan's early insistence on increased teaching duties and a longer working year will be somewhat softened and the duties are now being seen to be an overall requirement on a university, to be distributed according to some as yet undefined rules. The heavier teaching load will not be a direct requirement on individuals. The result of this, however, in conjunction with the law's insistence on free entry and on the evaluation of student need, may be to create a two-tier university structure in France. Some will teach, others will do research.

The pattern of research will also be transformed by the proposed change in the structure of higher degrees. The old *troisième cycle*, and the *thèse d'état*, respectively lesser versions of the PhD and DSc (the latter taking eight or nine years) are to be abandoned in favour of something approaching a PhD. This, most French scientists consider, will bring French science into line with the United States and Britain. But the new law has shrunk from out-and-out advocacy of meritocracy. As things are, would-be researchers can edge their way into laboratories on private means and eventually obtain a permanent post by waiting long enough, rather as in Italy. This system will continue even under the new law unless a comprehensive system of competitive grants is introduced. That step, still neglected, would do more than anything else to better the condition of science in France. □

Ivory tower in space?

NASA should be restrained from mounting a crash programme to build a US space station

THE National Aeronautics and Space Administration (NASA), set up in the heady days of the early 1960s, has always thrived on large engineering projects, undertaken on a crash basis with billions of dollars to throw about. Now that NASA has declared the shuttle operational (which, given recurring problems, including an explosion and fire after the shuttle's most recent

0028-0836/84/010001-02$01.00

landing, is not the case), it is once again at a loose end — whence the plan to build a space station. Although nobody — not scientists, not the military, not even NASA itself — has been able to figure out just why the United States needs a space station, President Reagan is expected to approve the project when he releases his budget for fiscal year 1985 later this month.

Perhaps it was just a coincidence, but just before Christmas, Congress's Office of Technology Assessment released a report that seemed to answer NASA's prayers. The report, a sober description of the Soviet Salyut programme, has been seized upon to provide the ultimate justification for an American space station; the Soviets have one. Unfortunately, an American crash programme to build a space station will fail to correct the real problem in the US manned space programme that the report identifies, and in the process will also do considerable damage to American space science efforts — an area in which the United States really does lead the Soviets.

All the media hoopla over the red menace has ignored the more serious underlying failing of the US space programme compared with that of the Soviet Union: while the Soviets have plodded steadily forward towards a directed goal — a continuous manned presence in space, built up through mastery of automatic docking and long stays in space — the United States has gone in for space spectaculars, virtuoso efforts that reflect a dazzling technical ability and lead nowhere. The Apollo project (which, as a Tom Lehrer song has it, spent billions of dollars of taxpayers' money to put some clown on the moon) was not part of a larger plan.

The shuttle, also a crash programme that took the lion's share of NASA's resources, has suffered from a lack of a sense of direction. NASA, in a political decision to sell the shuttle to Congress, tied everything it could to the shuttle — if space science was needed, the shuttle would do space science; if it was military satellites, the shuttle would do military satellites. To make sure, NASA ditched its reliable expendable launch vehicles. The result was a disaster for space science, though not for the reasons usually given. The shuttle project itself probably did not steal funds away from science; what it did, however, was to delay by four years the Galileo mission to Jupiter (Galileo, of course, was designed to use the shuttle), and the funds needed to keep Galileo going for four years (it will finally be launched in 1986) eliminated the possibility of doing anything else in space science in the meanwhile. Also, the early promises of 28-day missions have given way to the reality that it does not make economic sense to park a billion-dollar launch vehicle in orbit for a month. The presence of men on a scientific platform can also be drawback, particularly for sensitive pointing apparatus. The shuttle was not needed for science; in many ways, it has hurt science.

The space station seems to be following the same path. And it will be a tragedy if science is once again constrained to suit NASA's political expediencies. If the space station goes ahead as another NASA crash programme, there will be another two decades of original research on why astronauts vomit and whether you can make the perfect ball-bearing in space.

If the Administration is truly concerned about staying ahead of the Soviet Union, it would do well to concentrate on the existing strengths in the US programme. The series of inexpensive near-Earth space probes being developed by the Jet Propulsion Laboratory (see p.6) is one obvious avenue to pursue. Another is being studied by the Space Science Board and would make the shuttle into a truly useful scientific vehicle; it is to build a module, called Spartan, that could be dumped overboard from the shuttle, allowed to co-orbit with the shuttle (unmolested by men bumping about) and then picked up just before returning to Earth.

At the same time, more care and effort should be put into the shuttle and the space station, but in terms of an engineering development project — not a crash programme to build the space vehicle for the next decade. It is of course only a matter of time before there will be some real scientific (and perhaps military) needs for a permanent space station, and plans should be made for that. Meanwhile, the United States should learn something from the Soviet Union, and not waste energy on bursts of light and heat that hurt only itself in the long run. □

The year that never was

If 1984 is not as fearsome as in Orwell's novel, there are still important battles to fight.

AT the beginning of George Orwell's year, the first thing to acknowledge is that *1984* never came. The idea that governments might become so preoccupied with their own survival, and so adept at the exploitation of technology for bending the inclinations of their people to that simple goal, that personal liberty would cease to be, remains a nightmare — one, nevertheless, that will not go away. Moreover, this does not imply that governments are consistently more enlightened now than, say, a year ago, or that the suppression of liberty has by magic been banished from the face of the Earth. On the contrary, new pockets of despotism are forever cropping up. The mercy is that the practitioners of wayward offences against people are but crudely practised. Bullets, in their books, are more convenient than mind-control. And, as illiberal governments repeatedly discover, their wish to make their people toe some predetermined line is repeatedly undermined by the personal courage of those they would control. Precisely that obdurate unwillingness of people to forsake human dealings with each other is, after all, what changed Orwell's book from a political tract into a novel. Although the profession of science is superficially indifferent to the ways in which governments choose to treat their citizens, the health of science rests on the freedom with which new ideas flow from one place to another, from any person to any other. That, of course, is why professional scientists are concerned with the way in which their colleagues elsewhere are dealt with and why the fortunate among them have an obligation to assist those less fortunate by all possible legal means.

Against Orwell's predictions, the more serious anxiety during 1984 is not that governments will find it prudent to deprive their people of liberty but that they will choose to blow each other's people to smithereens. Outwardly, this again is an issue separate from the practice of science as such, or in which it might be held that professional people have a right to intervene only in their capacity as citizens. In many circumstances, that would be true. But if it is the case that the means of waging nuclear war, and the means by which the risks of nuclear warfare might be avoided, depend to a large extent on technical considerations, the technical community may be held to have an obligation to throw what light it can on the questions that arise. That is why journals such as this have always taken the position that comment on the steps which are being taken (or not being taken) to avoid the dangers of nuclear and other kinds of wars is not merely permissible but obligatory. And 1984 promises to be a busy year in this respect.

The year ahead also bristles with threats to the well-being of the scientific enterprise. The long recession is far from over (and will not be completed until the present period of rapid technological change has worked its way through the world's advanced societies). So even the most prosperous and far-sighted governments are in their different ways looking for ways of cutting costs wherever possible. The ambition is legitimate and laudable; the practice, unfortunately, is often ill-considered. This is why 1984 is likely to see a running battle between governments anxious to trim budgets by making science a pensioner of industry and those who see that the exploration and understanding of the world we live in cannot be trusted to such chance. Orwell's great book was written in 1948, when the first rudimentary electronic computers had just come into service, when the distinction between the pi and the mu mesons had just been discovered, when neither transistors nor lasers had been invented and when the mechanisms of inheritance were still unknown. That industrial needs have been the engines of many of these developments is not in question, nor is the prosperity that industrial developments have brought. The issue that will be fought in the months ahead is the extent to which free inquiry should depend on such adventitious interests. That battle too, looks like being a long and loud one. □

Intellectual property

UK patents shake-up causes a stir

A PROPOSAL to hive off the British Patent Office from the civil service and establish it as a separate statutory body is sending shock waves through the patent community. That suggestion is just one of several that are likely to prove controversial in a report on intellectual property rights recently published as a green paper*.

The report was produced at the request of the Prime Minister by Dr Robin Nicholson, Chief Scientific Adviser at the Cabinet Office, who holds that "cumbersome and slow" patent procedures are deterring would-be innovators in Britain. Smaller companies and individual inventors, in particular, tend to find the "arcane" world of the patent system a disincentive to stake a claim for patent protection. A new-look Patent Office freed from civil service constraints should, according to the green paper, be given broader terms of reference and encouraged to advertise its services and expertise, thus making fuller use of the database on patents that it maintains.

Nicholson has recently described the patent system in Britain as "dominated by a few very expert individuals" — a view apparently shared by a senior Patent Office figure who declines (for reasons of civil service etiquette) to be named but who feels the workings of the Patent Office have been partly misunderstood. And Mr Bernard Fisher, president of the Chartered Institute of Patent Agents, says that the green paper's main aim of getting the Patent Office to be more responsive to inventors' needs might be achieved more simply and more cheaply by simply allowing it to keep more of the profits it usually makes each year which are now returned to the Treasury. Pension rights and career structures would be greatly affected if the proposed changes were made, however, and allowance would have to be made for compensation payments.

The green paper urges a government policy statement on intellectual property, to include a number of changes. Some, such as the suggestion that service industries should be able to claim exclusive use of registered mark, have already been accepted by the government. Others are more contentious: the proposal to replace design copyright laws by a registered design scheme, in particular, will be unpopular with manufacturers of mass produced items, who are at present very well protected against competing manufacturers of spare parts, for example in the automobile industry. One critic of the Nicholson report said it might be impractical for manufacturers to have to register components individually, whereas as things stand ownership of engineering drawings confers copyright protection.

Nicholson comes down in favour of a system of "petty patents" — a form of short-term patent conferring only limited protection which can be upgraded into a patent proper if the putative invention justifies the cost and effort involved. The government has previously rejected this idea but changes in practice since the introduction of the 1977 Patent Act might now have swung the balance in its favour. The complaint from some industries is likely to be that their research and development programmes would be stultified if the number of potential monopolies were increased by petty patents.

Nicholson identifies several abuses of the patent system that are not adequately checked by existing safeguards. The aim is to prevent potentially valuable innovations from being "sat upon" by patent holders unwilling to risk exploitation. The 1977 act included provisions for compulsory licences to be issued to would-be innovators in such cases, but since the act was introduced only one has been granted. Nicholson says the existing provisions should be used more often and proposes new rights for employee inventors that would allow them to exploit an invention that is not taken up by their employer.

One proposal that is unlikely to be accepted without some resistance is that people other than registered patent agents should be allowed to represent inventors. The aim is to allow wider access to property rights and to promote price flexibility, but it is pointed out that inventors could lose all their rights if an inadequately prepared patent is published. The Chartered Institute of Patent Agents is apparently untroubled however, believing that serious inventors will always prefer the security of a registered agent.

One view of Nicholson's proposals is that they fail to take account of the constraints on Britain stemming from its participation in the European Patent Convention. There are certainly international issues at stake, particularly in seeking a balance between the legitimate interests of manufacturers seeking patent protection throughout the European Community, for example, and the risk of sanctioning anti-competitive practices. The document suggests that Britain should take the initiative in requesting the European Commission to devise proposals to straddle the gap.

UK research councils

Robbing Peter to pay Paul

THE Advisory Board for the Research Councils (ABRC) has recommended that funds for restructuring the British research councils during 1985–87 should come from within the science budget, according to Mr Peter Brooke, the Under-Secretary of State for Education and Science in a parliamentary reply. This tame-sounding statement has a sting to it. It means that the Medical Research Council (MRC) and the Science and Engineering Research Council (SERC) will, over that period, forgo 0.75 per cent and 1.5 per cent respectively of their budgets to pay for the forthcoming reorganization of the Natural Environment Research Council (NERC) and the Agricultural and Food Research Council (AFRC).

AFRC has been under pressure to reorganize partly as a result of earlier ABRC recommendations to cut back on financial support for the council (see *Nature* 22 December 1983, p.723). More recently, a study carried out by Sir Ronald Mason for ABRC suggested in unspecific terms that the amount of in-house research within AFRC and NERC was excessive. Both research councils are planning reorganization in the long term which is expected to involve expenditure on "early retirements, transfer costs and capital work", according to Mr Brooke. The science budget will be increased by £750,000 in 1984–85 and by £900,000 in the two succeeding years to offset some of this cost, while the total contributions from SERC's and MRC's forward planning budgets will amount to £3.1 million in 1984–85 and £6.3 million in 1986–87.

Mr Brooke also announced that an extra £1 million has been found partially to compensate SERC for increased subscriptions to international research organizations such as the European Organization for Nuclear Research (CERN), on top of the £6 million already secured from the Treasury. This still leaves SERC with about £3 million to find from its current budget next year.

In the circumstances, SERC and MRC are hardly likely to welcome the future loss of funds for research. Indeed, at a press conference in November, Professor John Kingman, chairman of SERC, emphasized the unfairness of a policy that penalized "efficient" councils. This reaction is apparently contradicted by Mr Brooke's statement that ABRC's policy is unanimously supported by the advisory board's members — who include the chairmen of all the research councils.

Philip Campbell

Radiation exposure

US academy study attacked

Washington

THE National Academy of Sciences has stumbled into an uncomfortable controversy about the health of American soldiers exposed to radiation when they were stationed near Hiroshima and Nagasaki after the cities were destroyed by atomic bombs in 1945. Veterans have for years been locked in dispute with the Department of Defense about the long-term health effects of their service in the area.

Last July, in a study requested by the Pentagon's Defense Nuclear Agency, the academy's research arm, the National Research Council (NRC), published a report concluding that there was no evidence to support claims that the veterans had suffered from an abnormally high incidence of the bone cancer called multiple myeloma. The fact that the report was immediately criticized as perfunctory by the National Association of Atomic Veterans (NAAV) caused little surprise.

But now, Congress's Office of Technology Assessment (OTA) has joined the fray. In a rare instance of Congress demanding a review of an NRC study, OTA says the report did not have enough evidence for its conclusions.

The academy's involvement goes back several years. In 1981, the Defense Nuclear Agency asked whether a large-scale epidemiological study of multiple myeloma was warranted. An NRC panel under Harvard's Brian MacMahon concluded that the low level of radiation to which US troops were exposed — about a tenth of a rad — could not have been responsible for the incidence of cancer. But the MacMahon panel also said that an epidemiological study might be necessary if estimates of the level of radiation encountered by American troops were revised upward or if there appeared to be *prima facie* evidence that veterans were suffering in disproportionate numbers from the disease.

In the wake of the MacMahon report, the Pentagon asked NRC to find out what it could about the incidence of multiple myeloma. A panel set up to review all known cases of myeloma among the veterans identified only nine — at the bottom of a range from 9 to 29 expected statistically in the normal population. It concluded in July (see *Nature* **304**, 200; 1983) that there was therefore no evidence to support claims of an abnormally high incidence among veterans.

OTA claims the NRC study has two basic flaws. The methods used to identify only nine cases of myeloma among the veterans were likely to result in an underestimate of the number who had actually contracted the disease. At the same time, NRC probably overestimated the number of cases that could have been expected if the rate of incidence was the same for veterans as for the general population.

Veterans who had contracted multiple myeloma were tracked down through a nuclear veterans' "hot line" established by the Pentagon and through a newsletter and magazine article organized by NAAV. The hot line had received calls from nearly 50,000 people by the time of NRC's study, of whom 678 reported service at Hiroshima and Nagasaki, and seven of those reported having multiple myeloma. NAAV found 21 names of people who had served in the two cities and had the disease.

NRC whittled down the 28 possible cases to nine. Eleven were eliminated because they appeared not to have served in Nagasaki or Hiroshima and six because they, their families or doctor failed to respond to follow-up enquiries. In another two cases, review of the clinical evidence found that they had not, in fact, suffered from the disease.

This procedure, claims OTA, was most likely to produce an underestimate of the number of cases. For one thing, the Pentagon hot line had produced only 4 per cent of the estimated 20,000 veterans who had served in Hiroshima and Nagasaki. For another, nearly half of those who contract multiple myeloma die within the first year, and at least some bereaved relatives may have failed to respond to the hot line, particularly as the advertising did not refer to multiple myeloma. Moreover of the 11 cases eliminated because they appeared not to have been at Hiroshima or Nagasaki, only seven were definitely known to have been elsewhere. And the loss of six cases because of failure to respond to a follow-up letter and telephone call could have had a dramatic impact on the overall result.

Finally, says OTA, the report compared the number of cases expected over a 35-year period with the nine cases it had tracked down — but all nine had been reported within a five-year period. OTA claims the comparison was inappropriate; its own calculation estimated the number of expected cases to be much smaller. Taken overall, OTA concludes, NRC's approach was unlikely to have detected a disproportionate incidence of multiple myeloma even if it existed.

NRC has not yet responded to OTA's criticisms, but in the view of at least one congressman the council has some explaining to do. Paul Simon, the Illinois Democrat sponsoring a bill to compensate "atomic veterans", said NRC's report had "tainted" debate about the complex issues involved. The methods and boldness of the report were bad enough, he added; more troubling was that its conclusions agreed so neatly with the views of the Defense Nuclear Agency, which had long denied government responsibility for the health problems of atomic veterans. **Peter David**

Indian science

Research council in trouble

New Delhi

THERE are skeletons in the cupboard of India's Council of Scientific and Industrial Research (CSIR). A scrutiny by a parliamentary committee has drawn attention to several shortcomings in the functioning of India's leading industrial research organization. The committee complains in particular that very few processes developed by the CSIR laboratories have been found useful by industry.

Only recently, Prime Minister Indira Gandhi was forthright in her criticism of the laboratories on the grounds that their research projects incur substantial losses. At a meeting of directors of national laboratories, she said that these are becoming an "ever-increasing burden on the nation" and asked that if there is no hope of the situation improving, "is it not time just to close them down?"

Now the parliamentary Public Accounts Committee (PAC) has revealed what ails these laboratories. Research projects have often been taken on without adequate planning in advance. The lack of machinery, equipment and other necessary facilities has later led to the abandonment of many such projects. In the past two years, about 300 projects have been dropped, reducing the number of schemes in hand to 1,543. A further hundred are to be terminated next year.

The officials concerned in evaluating these projects display a "superficial and perfunctory" attitude, according to PAC, which says that while unproductive and unfeasible projects should normally be abandoned after one year, some of them were allowed to continue for as long as five years. A glaring example is that of a household pump research project which had to be discarded after two years of work when it was found that the same project had been undertaken by another laboratory of CSIR three years earlier.

PAC has remarked that either the processes developed by CSIR were not selected with the needs of Indian industry in mind or CSIR has been unable to inspire the confidence of potential users in the usefulness of its processes. The council referred 295 of its technical development projects, less than half of those on its books, to the National Research Development Corporation (NRDC) for industrial exploitation, of which only 15 per cent had been taken up by industry by June 1981 — and some of these were withdrawn by CSIR.

Even public sector undertakings are not making full use of the council's research output. CSIR has been complaining of an "unsympathetic attitude towards development and utilization of indigenous know-how", saying that many of its

schemes are exposed to unfair competition "by the import of technology from abroad". It has been demanding a role in the selection of technology imports. It rankles that last year, CSIR technology for colour television was not exploited but that, instead, the government allowed the import of colour television sets.

The director general of CSIR agrees with the criticism that the council's laboratories concentrate on projects which serve the elite sections of society and pay little attention to technologies that could benefit people in economically weaker sections of the community. It has accordingly compiled a list of technologies to be developed for poor people.

Younger scientists have found support from PAC for their complaint that their views are ignored in planning the research work of laboratories. The committee says that funds allotted to their work are often arbitrarily transferred to other projects sponsored by more senior scientists, while younger people tend not to be included in the high-level committees of different laboratories.

CSIR is concerned that it can no longer attract scientists of high calibre for senior posts, partly because its laboratories are poorly equipped. One of its difficulties is the rapid inflation in the prices of chemical apparatus, equipment, books and journals, so that even a 10 per cent increase in its budget is not enough to catch up.

Sunil Saraf

Animal rights

Massachusetts bans strays

Boston

THE giving or selling of dogs and cats from city pounds and animal shelters to laboratories has been outlawed by the Massachusetts legislature. Responding to overwhelming public support for the measure, the bill has now been signed by Governor Michael S. Dukakis.

Animal rights advocates are claiming a major victory, as Massachusetts becomes the eighth state to prohibit pound seizure — the right of licensed laboratories to purchase unclaimed animals after 10 days. The law will end pound seizure from next October and the purchase of dogs and cats imported from out-of-state pounds from two years after that. Massachusetts is the first state to enact this provision.

Researchers who depend on so-called "random source" dogs and cats will now have to buy more costly "purpose-bred" animals from commercial breeders, or switch to other experimental subjects such as sheep, pigs, calves and goats. Ralph Charlwood, assistant director of the Harvard Animal Resource Center, says that the law will dramatically increase costs for heart, kidney and toxicology research that now depends on pound animals. Boston area medical schools are considering solving the problem of supply by establishing a jointly operated animal breeding facility, but even this approach would be more costly than buying cats and dogs from pounds.

Walter Kilroy, vice-president of the Massachusetts Society for the Prevention of Cruelty to Animals (MSPCA), claims that the law will improve the quality of research. "Random source animals are not good research models", he said. "Their genetic background and physical condition are much more variable than bred animals." Opponents of pound seizure believe that domesticated dogs from pounds suffer more stress than those used to kennel conditions and maintenance. "Laboratories taking dogs from pounds accept only those animals with personalities that allow them to be handled and restrained", said Kilroy. These are pets, accustomed to "human companionship and affection, and liberty".

Research institutions in Massachusetts — Harvard University and the University of Massachusetts in particular — have for several years been fighting highly organized efforts to repeal the pound laws; state legislators receive more mail on this issue than any other. ProPets, an alliance between the New England Anti-Vivisectionist Society (NEAVS) and MSPCA, collected more than twice the required number of signatures on a petition to put on this year's ballot a referendum far more

restrictive than the law now to be enacted. Unwilling to face the huge costs of fighting a state-wide referendum, the research institutions agreed to the new legislation in a compromise with ProPets hammered out by State Representative Ray Jordan.

Legislative efforts to prohibit pound seizure appear to be gaining momentum in other states. Aaron Madlock, director of the New England Anti-Vivisectionist Society, says his group will now campaign for similar legislation in Vermont, and points out that animal rights groups in California are engaged in a major battle to ban both pound seizure and importation from other states. Although universities, medical schools and pharmaceutical companies are now attempting to persuade the public of the value of animal research, they have plenty of catching up to do.

Christopher Earl

Soviet oceanology

Institute director in deep water

DR Andrei Sergeevich Monin, director of the Institute of Oceanology of the Soviet Academy of Sciences, has recently come under sharp attack in the Soviet media and from Communist Party activists within the academy. Charges against Dr Monin range from "the embezzlement of socialist property" (having his dacha repaired by institute employees and out of institute funds) to despatching research ships "round the world and back again" without a research programme for the whole journey, and from failing to ensure a "proper moral and political climate" in the institute's oceanological equipment design bureau (which is said to be run by a "close relative" of Dr Monin) to applying for the right to search for sunken treasure. Moreover, it is claimed, he has consistently ignored the criticisms of local and academy party officials, and has attempted to dismiss from the institute anyone who complained too openly of his policy.

As far as the corruption charges are concerned, the institute appears to have been made an example in Mr Andropov's much-publicized campaign for "work discipline". Unauthorized disbursements from the bonus fund and discreet "rectification" of over-demanding plans have become, alas, all too common a feature of Soviet management — including the management of scientific institutions. According to *Sovetskaya Rossiya,* several employees of the Institute of Oceanology's Leningrad branch have already been brought to trial on charges of "fraud and currency machinations". Nevertheless, it is alleged, the deputy director, L.A. Tzymbal, who was discovered to have sanctioned and received illegal salary increments, is still working at the institute under Dr Monin's patronage.

Dr Monin has, apparently, so far managed to quash all complaints against him, including those made to the academy. Letters of complaint get bogged down in the bureaucratic process or else receive smooth and non-committal answers. Several leading oceanologists have allegedly left the institute in disgust at the director's seeming inviolability. Meanwhile, Dr Monin himself has a standard answer to every criticism: it is all due, he says, to the "growing pains" of the relatively young science of oceanology.

Vera Rich

Correction

The accidental sea discharge at Sellafield reported in *Nature* (**306**, 721; 1983) was made through the normal sea pipeline, and not as stated. The 2-inch pipe was used in an attempt to return waste from the sea tank to the plant. □

US space plans

Economy flights in prospect

Pasadena, California

CUT-rate planetary missions have been included in the 1985 budget request of the National Aeronautics and Space Administration (NASA). The series of probes, known as "Observer", will use modified Earth-orbital satellites to explore the nearby planets. The first flight could take place in 1982, with subsequent missions at one to two year intervals.

The new probes would add significantly to the modest resurgence in planetary exploration of the past year. Congress this fall approved funds for the Venus Radar Mapper mission, the first new planetary mission since Galileo. Galileo, which was to have been launched on its journey to Jupiter in 1982, was repeatedly delayed by setbacks in the shuttle programme, and is now scheduled for 1986.

Costs for the Observer probes will be kept down by designing instruments to fit available vehicles, rather than the other way around as in past practice. The Jet Propulsion Laboratory (JPL) here, which has primary responsibility for planetary missions, is ready to issue a request for proposals from satellite manufacturers for supplying the vehicles. Possible candidates include the RCA weather and communications satellites, TRW's satcoms, and Hughes communication satellites. By limiting the Observer missions to the nearby planets, Mars and Venus, requirements for power, temperature control and communications systems will be modest and can easily be adapted to fit the adapted Earth-orbit satellites. One of the first Observers is expected to be a Mars orbiter that will probe the geochemistry and climate of that planet.

The renewed hopes for planetary science come just two years after JPL, finding it hard to keep its staff employed, sought and received unprecedented permission from California Institute of Technology (which operates JPL for NASA) to take on defence contract work in an amount up to one-third of the laboratory's total operating budget. But with things looking up (besides the Venus Radar Mapper and the hoped-for Observers, JPL is busy with Galileo and the forthcoming rendezvous of Voyager with Uranus and Neptune), the laboratory expects to hold the defence work to its present level of 20 per cent.

JPL also has plans for more ambitious planetary missions. So-called Mariner Mark II probes, which similarly would draw on existing hardware designs, are being planned for exploration of more distant planets and perhaps comets; one much discussed idea would be a Saturn orbiter that would carry an entry probe to be dropped into Titan, Saturn's volcanic moon. Both the Observer and Mariner Mark II flights could be carried out under a $300 million annual budget, according to JPL officials. The Mariner Mark II probes would be launched every two to three years.

Much less is being heard about grand, novel missions, such as a sample-return mission to Mars. JPL officials see those as "augmentation" missions that will only be contemplated if extra money becomes available. **Stephen Budiansky**

Soviet space programme

Not without hitches

AFTER more than three months of Western speculation, Soviet cosmonauts Vladimir Lyakhov and Aleksandr Aleksandrov have at last admitted that during their 150-day mission aboard the Salyut-7/Soyuz-T9 complex, there had indeed been a "slight" leak of propellant, although, they said, this "had not affected either the flight or the research programme".

Ironically, on the same day that the cosmonauts talked about their flight at a press conference in Moscow, *Aviation Week and Space Technology* published further claims about the Lyakhov-Aleksandrov mission. During their final weeks aboard the station, it was claimed, the cosmonauts had had to endure "cold, damp and uncomfortable conditions" due to a "solar array problem", that had "reduced electrical power and seriously affected" the environmental control system. The crew's two space walks on 1 and 3 November, *Aviation Week* said, had been necessary to install additional solar panels, in order to save the station from becoming uninhabitable in the near future. When the loss of environmental control became serious, *Aviation Week* claims, the Soviet planners decided to "train and launch" a repair crew — cosmonauts Vladimir Titov and Gennadii Strekalov. When the launch had to be aborted because of a fire in the booster-rocket, however, Lyakhov and Aleksandrov had to carry out emergency repairs themselves.

According to the Soviet flight controllers and the cosmonauts themselves, however, the work on the solar panels had always been "one of the most responsible parts" of the original flight programme. The new panels were needed, they explained, to increase the power supply of Salyut-7 so that more experiments could be performed simultaneously. Deployment of the panels, moreover, had confirmed that the techniques and procedures proposed for large-scale assembly work in space, are, indeed, practicable. It also provided data for evaluating and improving the ground-level training programme for such assembly work in space as well as useful feedback for the designers of space-suits.

The Soviet claim that the deployment of the panels was from the beginning an integral part of the flight programme accords with recent hints that the construction of a permanently-staffed orbital station (always a long-term aim of the Soviet space programme) is now a definite project. Moreover, if it were simply an emergency repair job, carried out in the absence of the trained "repair team", it is remarkable that Lyakhov and Aleksandrov could carry it out without, apparently, undue difficulty. According to their own account, however, the cosmonauts had carefully practised the whole procedure (in the simulation tank) and the flight-plan had been worked out so that the main operations were carried out within the radio-visibility zone and in the illuminated part of the orbit. The special equipment, moreover, used in deploying the panels included not only tools and manipulators, but also non-slip safety handrails — once again, substantiating the Soviet claim that this was a pre-planned "experiment", not an emergency repair job. **Vera Rich**

French get hooked

JUST before Christmas the French post office, PTT, inaugurated "Minitel", an electronic telephone directory designed to lead the French market into the Elysian Fields of the "hooked-up home".

Minitel has been on trial in Brittany and Versailles, but now the experiment has been extended into part of Paris. By March, there should be 50,000 sets operational in the centre of France, and 3 million should be in action by 1986.

Basically, Minitel is designed to replace paper directories: a user dials 11 to link up to a local computer, and then — using a keyboard — answers a few questions to tell the computer the name (and/or address) whose number is sought. The answer is displayed on a small television screen. But of course, with such technology in place many other uses spring to mind — one option is screen-to-screen communication between two Minitels, so the deaf can use the telephone.

In Velizy-Versailles PTT has offered other services: banking, cinema booking, rail timetables, stock exchange prices, even a newspaper; and the take-up has been moderate. One-third of the Minitel owners (who like the others in the experiments have been given them free, though those outside experimental areas can rent them at £6 a month) do not use the machines at all; but the other two thirds use them an average of 40 minutes a week. The biggest users are those with children between 12 and 15; the smallest, retired people.

Where people have been offered the choice of a Minitel or a conventional directory, 46 per cent have chosen Minitel. It is nearly the figure forecast by PTT (50 per cent), but not enough yet to encourage PTT to abandon its printing machines.

Smallpox eradication

Military use of vaccine criticized

Washington

NEARLY four years after smallpox was universally eradicated, the US military is still administering the vaccine as a "defensive and deterrent measure" against the use of smallpox virus as a biological weapon. This policy has put the US Army indirectly at odds with the World Health Organization and the US Centers for Disease Control (CDC), both of which have been working to eliminate all use of the vaccine. 'We've had several deaths and significant morbidity from its use for non-indicated reasons", says Dr Stanley Foster, assistant director of CDC's international health programme office. The main civilian users have been physicians who either did not know that smallpox had been wiped out or who believed that smallpox vaccine was effective against genital herpes. CDC last spring persuaded Wyeth Laboratories, the only remaining manufacturer of the vaccine in the United States, to take the product off the commercial market. Wyeth had at last count been selling some 50,000 doses per year.

Wyeth is, however, continuing to supply the military. All active duty personnel and reserves are vaccinated on a five-year schedule — which amounts to several hundred thousand doses per year. The military has also requested Wyeth to supply a stockpile of the vaccine sufficient to dose a classified number of personnel in the case of a general call-up.

Adverse reactions to the vaccine, which contains live vaccinia virus, are rare, but not insignificant. According to CDC, one death can be expected for every million persons vaccinated. Generally less severe reactions (although sometimes fatal themselves) occur more frequently, mostly in certain susceptible groups — immunocompromised subjects (about 7 reactions per million vaccinations) and those with eczema (38 per million).

Dr James Kirkpatrick, an army lieutenant colonel who advises the Army Surgeon General's office on the smallpox vaccination programme, says that by exempting personnel with eczema (or who have a family member with eczema), the military has kept the rate of adverse reactions quite low. All vaccinations (including measles, rubella, tetanus, smallpox and a half dozen others) resulted in 60 hospital admissions a year, he said, with an average hospital stay of two days. Although no numbers are available for the rate of adverse reactions specifically from smallpox vaccinations, CDC says it receives about one request per month for vaccinia immune globin, which is used to treat reactions to the vaccine. All such requests since last spring have been from the military.

The military's reason for vaccinating against smallpox appears to be intelligence information that the Warsaw Pact nations and the People's Republic of China vaccinate their troops. "Nobody can rule out the possibility" that smallpox would be used as a weapon, Kirkpatrick says, and it "would not be prudent" to stop vaccinating. According to CDC, only the United States and the Soviet Union continue to maintain stocks of the smallpox virus. South Africa recently and with much fanfare announced the destruction of its stocks.

Although CDC has been careful not to criticize the military programme directly, CDC officials are known to be uneasy. And a number of smallpox researchers have questioned whether the supposed threat of smallpox as a biological weapon outweighs the known risks of vaccination. Smallpox has an 8–10 day incubation period and is not very infectious. Epidemiologic evidence shows that 30–40 per cent of susceptible members of a household will catch the disease from an infected member, compared with 80–90 per cent for measles, for example. They also point out that smallpox virus would live only a matter of hours in an aerosol form, the presumed method of delivery as a weapon.

The use of smallpox vaccine by civilian physicians as an unorthodox treatment for genital herpes has been a bizarre footnote to the story. Controlled studies have demonstrated no benefit in preventing or healing herpes lesions; CDC has nonetheless received many calls from herpes patients protesting against CDC's role in removing the vaccine from the market and claiming that the vaccine was the only thing that had helped them. CDC officials say that some physicians had also apparently been using the vaccine as a general "tonic", supposedly to boost a patient's immune defences.

Stephen Budiansky

US dioxin question is tackled

Washington

A MAJOR new programme to deal with dioxin has been unveiled by the Environmental Protection Agency (EPA), fulfilling a promise made by William Ruckelshaus when he became its administrator last spring. The programme will include investigations at hundreds of chemical plants and waste disposal sites at a cost of up to $250 million over four years. Alvin Alm, EPA's deputy administrator, says the agency regards dioxin as one of the most perplexing and potentially dangerous chemicals ever to pollute the environment. The programme would concentrate on what was considered the most toxic of the 75 dioxin isomers — 2,3,7,8-TCDD, which is known to cause chloracne in humans. In laboratory animals, it has been known to cause cancer, reproductive failure, reduced effectiveness of the immune system and significant changes in enzyme systems. EPA's Cancer Assessment Group says it should be regarded as both an initiator and a promoter of cancer.

The agency's top priority will be an investigation of sites at which the herbicide and feedstock chemical 2,4,5-TCP was manufactured or disposed of. The chemical was used in the manufacture of 2,4,5-T and silvex, well-known herbicides widely used until recently to control weeds and as defoliants. 2,4,5-T was an ingredient of Agent Orange, the defoliant used in Vietnam. In a background document, EPA admits that little is known about the effect of dioxin on humans. A single dose of less than a millionth of a gram can kill a guinea pig, but its potency varies enormously between species. Information on the effects of human exposure is scarce. It is agreed that dioxin can cause chloracne but it has not been proved that it can also cause soft tissue sarcoma.

The uncertainty has resulted in a chequered history of regulation, and in October last year the Dow Chemical Company voluntarily cancelled its registration of the products.

Peter David

Richter to head SLAC

Washington

BURTON Richter has been named to succeed Wolfgang Panofsky as director of the Stanford Linear Accelerator Center (SLAC). Richter, who won the Nobel Prize for Physics in 1976 (with C.C. Ting) for the discovery of the psi particle, will take up the post next September. Richter is the designer and prime mover of SLAC's linear collider, on which construction began two months ago. The $113 million machine consists of a one-and-a-half mile loop attached to the main linear accelerator; electrons and positrons accelerated in the linear stretch will collide in the loop at centre-of-mass energies of up to 100 GeV. The linear collider, like the much larger LEP machine under construction at the European Organisation for Nuclear Research (CERN) at Geneva, will find its greatest application in detailed studies of the Z^0 particle. The electron-positron collisions are much cleaner and easier to interpret than the proton-antiproton collision used at CERN last year to detect the heavy bosons (Z^0 and W^+/W-). Unlike LEP, however, the linear collider will be breaking new ground in accelerator design — a design that Richter says will yield considerable cost savings over LEP's traditional ring structure.

Panofsky, who has directed SLAC since 1961, decided to follow his own policy of retirement at the age of 65 for the laboratory's administrators but will act as a technical adviser. Stephen Budiansky

Releasing "ice-minus" bacteria

SIR — Two strategies for the biological control of those bacteria that act as seeds for ice-crystal formation (and the consequent crop damage) have recently been presented. Researchers at the University of Colorado propose spraying fields with bacterial viruses (bacteriophage)[1], while researchers at the University of California propose spraying fields with genetically engineered bacteria whose "ice-nucleation gene" has been deleted[1,2]. Most of the media attention has gone to the latter stratagem, largely because of the controversy surrounding the release of recombinant DNA organisms into the environment[2,3]. However, successful implementation of these strategies may be limited by ecological and evolutionary factors subsequent to the deployment of predators (bacteriophage) or competitors (recombinant bacteria). The application of bacteriophage to populations of sensitive bacteria engenders intense selection for phage-resistant mutants[4] whose increase could defeat future, if not present, control. The application of recombinant "ice-minus" bacteria requires that they outcompete naturally occurring ice-nucleating forms[2], whereas the arbitrary deletion of an evolved gene would likely be disadvantageous, or at best neutral.

An integrated strategy might overcome these difficulties, and might even begin to counter some of the fears associated with releasing recombinant bacteria. Bacteriophage infect bacterial cells by first adsorbing to some surface protein or other component of the cell wall; phage are generally very specific in their site of adsorption[5]. By comparing the sensitivities of "ice-minus" and "ice-plus" isogeneic bacteria to a diverse set of bacteriophage, one might identify a phage whose site of adsorption is the ice-nucleating surface protein. By applying this bacteriophage in concert with the "ice-minus" recombinant bacteria, one would provide the "ice-minus" phage-resistant bacterium with a strong selective advantage over the "ice-plus" phage-sensitive natural counterpart. Moreover, as phage-resistant mutants appeared among the naturally occurring bacteria, they too would probably be "ice-minus" since resistance to phage typically arises via the alteration or loss of function of the gene encoding the specific surface protein to which the phage adsorbs[5]; even if such phage-resistant mutants were not "ice-minus", selection favouring their increase would be ameliorated by high densities of the phage-resistant recombinant competitor. Finally, with this strategy, it should be possible to release "disarmed" strains of "ice-minus" recombinant bacteria — recombinant strains bearing genes (or deletions of genes) which ensure their competitive inferiority outside the range of simultaneous application of bacteriophage, yet whose phage-resistance renders them selectively favoured within the range of simultaneous phage application. Thus, the spread of recombinant bacteria would be prevented by virtue of their competitive inferiority coupled with their inability to support the very phage whose presence is necessary to permit their establishment.

Is there a precedent for this strategy? Williams Smith and Huggins[6] successfully treated experimental bacterial infections in mice using bacteriophage, precluding the rise of phage-resistant bacterial mutants in a manner similar to that proposed above. First, pathogenicity of the target bacterium was shown to depend on the presence of a particular surface antigen[7].

Second, a bacteriophage was isolated whose site of adsorption is that surface antigen. Third, it was shown that the bacteria became resistant to the phage through the loss of that surface antigen. In essence, Williams Smith and Huggins chose phage for which resistance was incompatible with pathogenicity of the target bacterium. Whether phage can be isolated for which resistance is incompatible with ice-nucleation by the target bacteria remains to be seen.

How "gradual"?

SIR — The recent article by Rhodes[1] on "Gradualism, punctuated equilibrium and the *Origin of Species*" is a major event in clarifying Darwin's views on both rates of evolution and "gradualism". The claim that "gradualism" refers specifically to long-term regular changes in the geological record[2] has led to much confusion. It is now clear[1] that Darwin's views on gradualism should be understood on a shorter biological or ecological time scale[3], and that they do not require (nor could they explain) slow, long-term, orthogenetic changes in the fossil record.

There is one point that has not been covered and which helps to establish how (apart from misquotation[3]) the misunderstanding arose. It may also help to prevent such errors in future. This is that terms such as "fast", "slow" and particularly "gradual" have no scientific relevance unless they are used with respect to a specified time scale.

The term "temporal solipsism" has been used by Kamen[4] to describe the confusion that arises when conclusions are applied to the wrong time scale. His example is photosynthesis and he pointed out that it can be studied over many different time scales. Radiation physicists study quantum processes that occur within 10^{-15} – 10^{-9} seconds, or even longer. This "era" extends over at least six orders of magnitude, and overlaps with the time frame of photochemistry which studies events from 10^{-9} to about 10^{-4} or 10^{-3}s. Biochemists study events occurring from about 10^{-3} up to 10 s, and physiologists extend the range up to 10^{4}s. Crop physiologists, farmers and ecologists extend the domain to at least 10^{9}s. But long-term evolutionary changes such as the relative sensitivity of carboxylating enzymes to CO_2 and O_2 (ref. 5), development of C_4 photosynthesis and crassulacean acid metabolism, extend into the domain of more than 10^{16}s.

Given this extraordinary range of 10^{-15}–10^{16}s, it is clear that "fast", "slow" and "gradual" are meaningless unless a temporal frame of reference is given. The interpretation suggested is that some palaeontologists have shown "temporal solipsism" by assuming that gradualism referred specifically to a geological time scale. It is clear[1,3] that Darwin, in writing a book for a general readership, was referring to a biological or ecological time scale[1,3] in discussing small, gradual changes between generations. Such a process does not predict orthogenetic trends in the fossil record.

Be kind to flies

SIR — E.G. Gray's method for swatting flies[1] may work[2] but must always result in the death of the fly which cannot be justified unless the insect in question really is a health hazard. Last Christmas I bought my arachniphobe family a simple device called a "Spider Scoop". This consists of a transparent plastic dome mounted scissor-like on a broad plastic base. The dome is put over the offending arthropod and the base gently brought into place trapping the animal inside it. The principle resembles that of the card and beaker technique[3]. I recommend this method of fly trapping as efficient, clean and kind.

New window on Tibetan tectonics

The latest reports from the Sino-French expedition in Tibet show a rich and surprising harvest of discovery. Has not the time come for more open access to this important region?

TIBET has always been a mysterious place. In the nineteenth century, wide-eyed explorers wrote of the region with an innocence unclouded by the circumstance that Marco Polo had passed that way some centuries earlier. Physical isolation has all along been enhanced by human geography, and in particular by the self-imposed isolation of the Tibetan people, broken chiefly by expeditions bent on climbing Mount Everest. The consequence is that very little has been learned at first hand of the most rudimentary geological characteristics of this remarkable region and that many of the attempts in the past few years to relate the tectonic structure Tibet (and much of the rest of central Asia) to the tectonic collision of the Indian subcontinent with the Asian land-mass have had to rely to an unhealthy degree on inferences from topographical features.

Now, at last, there is a good chance that some of these uncertainties will be removed. The group of articles appearing on pages 17–36 is the second instalment of the fruits of the Sino-French collaboration on the geology of Tibet (see also *Nature* **294**, 405-417; 1981). In two successive seasons (1980 and 1981), modern techniques have for the first time been applied to the study of the gross tectonic structure of Tibet. By means of seismic records from artificial explosions, it has in particular been possible to map beneath Tibet the Mohorovicic discontinuity which is probably the best indicator of the continental basement. The result is both important and surprising.

That the collision of the Indian subcontinent with the Asian underbelly must have had a dominating influence on the structure of central Asia has been evident since it was first recognized that the Indian subcontinent traversed the whole length of the Indian Ocean from about 50 million years ago until its collision with Asia rather more than 20 million years ago. The join between the two continents is recognizable in the long east-west suture along part of which the Brahmaputra flows eastwards, north of the Himalayas. The Himalayas themselves are explicable as tectonic consequences of the collision between two land-masses — formed from material uplifted from the northern leading edge of the Indian subcontinent and partly metamorphosed in the process.

In recent years, the bigger puzzle has been that of understanding what may have happened north of the suture, beneath Tibet itself. The great elevation of central Asia suggests that an ancient continental crust has been thickened, while the predominantly east-west alignment of major features between the Caspian Sea in the west and mainland China in the east suggests crustal shortening in a north-South direction and extension at right angles. Whether the elevation of central Asia might be explained by the addition of Indian material to the underlying basement, almost as if the southern continent were sliding beneath Asia, has been a lively issue amongst geophysicists.

What now emerges from the Sino-French study of Tibet along two north-south traverses is that the simple picture of a once-and-for-all collision is too simple. The most striking result of the data gathered by the 1981 expedition is that there is a second suture in the tectonic structure of Tibet which, on the face of things, is in every way comparable with the southern suture but some hundreds of kilometres further north. The inference is that the collision of India with the underside of Asia was preceded some tens of millions of years earlier by the collision of another continental fragment with the same region. And that layer of material has been thickened, and elongated from the east to west, between the anvil of the main body of Asia to the north and the still-moving hammer of India, now shown to be moving relative to the Tibetan blocks at about 5 centimetres a year.

The evidence for this new view of the recent history of south-central Asia is impressive. Palaeomagnetic measurements show that the Lhasa block, the first tectonic structure north of the Himalayas, was sited at or south of the Equator in Cretaceous times. In the region covered by the Sino-French surveys, the continental basement is a patchwork suggesting that the high plateau of central Asia is made up not simply of two fragments (the Indian subcontinent and its predecessor) but of several. And there is evidence to suggest just how relics of past continental fragments underline each other, contributing to the thickening of the continental crust throughout this region.

For those with an interest in the evolution of Gondwanaland, these developments must be portentous. On the simplest reconstructions, Gondwanaland is an amalgam of those continents lying on or south of the Equator. Both the manner of their assembly into a larger continent and the timing of their dispersal are reasonably well catalogued. But the reconstruction of the supposedly earlier super-continent in which the northern land-masses are also combined has always been more speculative and less certain.

If now it is clear that the shapes of many of these structures have been distorted by later tectonic events, the awkwardness of more ambitious reconstructions will be better understood. But naturally, the question will be sharpened why a whole series of continental fragments should have been sent scurrying north across the Indian Ocean in the past few hundred million years. Why in that direction and not some other? Or was the assembly of southern Asia an even more complicated process than it now appears to have been?

For others, the work now published is still not enough to satisfy legitimate curiosity about this geologically important region. Moreover, it is clear that what has been accomplished in a few short seasons of work with modern equipment is merely a scratching of the surface. In an ideal world, there would now follow a systematic programme of exploration designed to amass the details on which accurate interpretations can alone be based. (Why, in any case, should there have been a single land mass in the early Cambrian?)

The obvious snag is that Tibet is almost as inaccessible now as in the days before its annexation by the People's Republic of China. The collaboration with the French is the only significant opening to the outside world so far. In everybody's interests, those of the people of China especially, there need to be many more. And readers of the articles now published will be struck by the irony that the 1981 Sino-French expedition was prevented for administrative reasons from continuing north beyond Tibet into China proper. The time has surely come when such restrictions should be swept away.

John Maddox

Sir Charles Frank

IN an article on snowflakes in *Nature* on 3 November (**306**, 13; 1983), it was erroneously stated that Professor F.C. Frank (whose name was mis-spelled) of the University of Bristol had died in 1982. *Nature* is glad to report that this is not the case and wishes to apologize to Sir Charles, his friends and colleagues and its other readers for this embarrassing mistake. □

Neurological disease

Of Mice and Men

from J. B. Martin

SPONTANEOUS autosomal recessive mutations in mice are providing novel neurobiological models for studies of disorders of the central and peripheral nervous systems[1]. The clinical syndromes observed in such mice are given graphic anthropomorphic names: weaver, shiverer, wobbler, totterer, reeler, twitcher, and so on. Such mutants are being carefully investigated in search of clues to the pathogenesis of their disorders, both to gain an understanding of normal development of the brain and to seek hints to the nature of genetic disorders that affect the human central nervous system. Anatomic and biochemical studies of each mutant type have revealed some interesting abnormalities in brain, spinal cord or peripheral nerve. In general, homozygotes are severely affected; heterozygotes less so. Two such mutants have recently been the subject of new biochemical and anatomical investigations. In the shiverer mouse, which fails to synthesize myelin basic protein (MBP) — the most important constituent of the sheath of central nervous system axons — the defect has now been identified as a mutation in the structural gene for the protein[2]. And weaver mice, best known for cerebellar abnormalities, are, in a paper published in this issue of *Nature*, shown for the first time to have a highly selective degenerative disorder of subcortical dopaminergic systems somewhat reminiscent of certain human neurological disorders[4].

The brains of homozygous shiverer mice contain less than one per cent of normal levels of MBP; heterozygotes contain about 50 per cent, indicating a gene dose effect. Demyelination is prominent throughout the CNS and is believed to be a contributory cause of the clinical symptoms.

The recent work by Roach and co-workers[2] is the first successful attempt to relate a structural protein defect to an abnormal gene in mutant mice with neurological syndromes. Working from the known structures of mice and rat MBP, which share close homology[3], the investigators synthesized DNA probes based on the reverse translation of the amino acid sequence of rat MBP. Two cDNA clones encoding MBP were selected and a restriction enzyme fragment from one was completely sequenced. When translated, a portion of this sequence was identical at 126 of 127 positions with the known amino acid sequence for small MBP in the rat. Brains of shiverer mice homozygous for the MBP defect had greatly reduced concentrations of MBP mRNA compared to wild type. With the use of Southern blots for genomic DNA, it was shown that MBP sequences are deleted in shiverer mice. These studies have considerable implications for the investigation of demyelinating diseases in man. Multiple sclerosis, though usually a sporadic not an inherited disorder, has an increased incidence in individuals with certain tissue types (HLA-A3, B7, Dw2) suggesting a genetic propensity for the disorder, at least in some individuals. More important, the fact that rodent (rat and mice) MBP is closely similar in structure to human MBP points to the potential advantage of using such animal models to investigate human afflictions. It is likely that an understanding of the gene transcription and post-translational processing of MBP will increase our understanding of the aberrations of this important protein in the human.

In this issue of *Nature*, Roffler-Tarlov and Graybiel[4] describe an intriguing biochemical and anatomic study of the dopamine abnormality known to occur in the brain of the weaver mutant. Previous studies of this mouse focused on the cerebellum where abnormal migration and death of granule cells were noted[5]. The weaver strain also has a partial deficiency of dopamine in the forebrain[6]. The important contribution of the new report is the demonstration that one dopamine system, the nigrostriatal, is affected, whereas the other, the mesolimbic, is normal. The biochemical deficiency of dopamine in the putamen and caudate is mirrored by an alteration in the specific histofluorescence of the amine-containing neuronal elements. The dorsal striatum, which has a rich innervation from the nigrostriatal tract, shows dopamine depletion, whereas the ventromedial striatum and the nucleus accumbens, innervated by the mesolimbic system, are normal. The authors point to a lack, at the moment, of a similar disorder in humans but make analogies between this genetic disorder and the pattern of cell degeneration in Huntington's disease, an autosomal dominant human disease, recently shown to be associated with a DNA polymorphism on chromosome 4 (see refs 6 and 7). The regional distribution of the cell death that occurs in Huntington's disease is similar. Specifically, the area of the basal ganglia most affected in Huntington's disease is the dorsal lateral region of the caudate and putamen (neostriatum). In contrast, the substriatum, in particular the nucleus accumbens, is relatively spared[8]. The possibility of discovering genetic models of disease with topographic features similar to those present in man is raised by these observations.

The defect in the weaver mouse more closely approximates that of Parkinson's disease, which is usually a sporadic illness, but occasionally occurs as a hereditary or familial disease. The exact nature of the cellular pathology responsible for the dopamine deficiency in the weaver mouse has yet to be defined, and its genetic basis is unknown.

Mutants may also be useful models for exploring new therapeutic approaches. When grafted nerves of twitcher mice, which are defective in the enzyme galactosylceramidase (a model of Krabbe's disease), are transplanted into normal mice, the enzyme defect is corrected after several weeks[9]. Enzyme replacement occurs from adjacent normal tissues pointing to a possible strategy for correcting enzymatic defects. It is likely that future studies of mice mutants will provide additional examples of nature's errors which are applicable to an understanding of human diseases. In search of these, it is evident that defined biochemical changes rather than descriptive anatomic studies will provide the important leads to follow. □

100 years ago

PROF. J.P. Licherdopol writes from Bucharest, Roumania, that on January 1, at 6.13 a.m., two horizontal shocks of earthquake, from north to south and *vice versâ*, were felt there, and were preceded by a loud noise, as of a distant train coming from the north. The furniture was slightly shaken and crackings were heard. The atmosphere was calm, but charged with a very thick and persistent fog.

A series of ornithological observatories has been established throughout Austria-Hungary at the instance of Crown Prince Rudolf, with a view of paying special attention to the migrations of birds, as well as to their breeding habits. The work done by these stations is satisfactory enough; yet it has been found that a complete insight into the periodical movement of birds cannot be obtained so long as similar stations are not spread over the whole globe. The subject is to form one of the principal topics for discussion at the approaching Ornithological Congress, which will be held under the auspices of the Crown Prince at Vienna on April 16 next and the following days.

From *Nature* **29**, 244; January 10th, 1884.

Medical genetics

Molecular diagnostic medicine

from Peter Newmark

FOR too many years those who felt obliged to respond to the taunt that molecular biology, for all the medical research money it had soaked up, had never done anything to help diagnostic medicine, could, at best, just about fall back on the case of thalassaemias. The extent to which the situation has changed in the last few years was well illustrated at a recent Titisee conference* and has since been spectacularly demonstrated in the case of Huntington's disease.

A key to much of the recent progress, including that with Huntington's disease, has been the use of restriction fragment length polymorphisms as genetic markers of disease. Remarkably, they provide a means of detecting the presence of a hereditary genetic lesion, even when the lesion itself is completely elusive. The theoretical basis of that approach was described in great detail three years ago (Botstein, D., White, R.L., Scolnick, M. & Davis, R.W. *Am. J. hum. Genet.* **32**, 314; 1980).

Restriction fragment length polymorphisms are the fortuitous result of variations in DNA sequence which are detectable because they generate (or eradicate) cutting sites (short, specific sequences of base pairs) for one or another restriction enzyme. Therefore the restriction fragments produced by the enzyme from the two alleles will differ in length. Since fragments of different length can be separated (by agarose gel electrophoresis) and detected with specific DNA probes (Southern hybridization) it is possible to determine (prenatally, if necessary) which form of a polymorphic sequence is carried by any individual and through any family.

To make use of that information for diagnosis it is necessary to find at least one and preferably several polymorphisms that are close enough to the chromosomal locus of the disease to minimize the chances of becoming separated from it by genetic recombination during formation of gametes.

It is important to remember that the polymorphisms are not the result of the lesion that caused the disease but simply a pre-existing variation in the population at large. Therefore which of the polymorphic restriction fragment lengths will be linked to the disease in any one family will depend upon which one existed on the ancestral allele in which the lesion arose and from whose bearer the family is descended: the case of Huntington's disease illustrates how two families have a different restriction fragment marker linked to the disease. Moreover, there is always a chance, sometimes high, that the same restriction fragment that characterizes the ancestral lesioned allele will be 'imported' into the family on the same chromosome as an unlesioned allele — hence the necessity for family studies.

In Titisee, Duchenne muscular dystrophy and the Fragile X mental retardation syndrome were discussed as examples of diseases for which restriction fragment length polymorphisms should aid both prenatal diagnosis and, eventually, the ability to identify the mutant gene. Both diseases are known to be located on the X chromosome and so it has been immediately possible to narrow down the hunt for restriction fragment length polymorphisms that lie close enough to the mutant gene usually to remain attached to it. K. Davies (St. Mary's Hospital Medical School, London) briefly described a polymorphism that is loosely linked to the 'fragile site' near the tip of the X chromosome whose breakage is associated with mental retardation; a more closely linked polymorphism is one that is known by its association with the gene for the blood coagulation factor IX (G. Camerino *et al. Nature* **306**, 761; 1983).

For Duchenne muscular dystrophy, Davies offered two polymorphisms, one on either side of the mutant gene. Neither is linked closely enough for confident prenatal diagnosis in affected families but they have nonetheless proved useful for carrier detection, particularly in families where both occur. Unfortunately, between one-third and one-half of muscular dystrophy cases are the result of new mutations and so will never be detectable without prenatal population screening, which is unthinkable.

The distance of each polymorphism from the mutant gene — around 15×10^6 base pairs — will also make difficult the other goal, that of identifying the mutant gene by working in from the polymorphisms. Davies makes the reasonable assumption that the mutation is in a gene that is normally expressed and therefore should be identifiable by an RNA transcript that corresponds to the gene. She estimates that the search is for one transcript in about a hundred that will be specified by the sequences lying between the two polymorphisms.

An alternative approach was described by E. Southern (MRC Mammalian Genome Unit, Edinburgh). It begins with some very rare female sufferers from muscular dystrophy (it being a recessive disease, females are usually only carriers). The female sufferers are characterized by the presence of an X chromosome translocation, always involving the same band of the X chromosome but with different autosomes partaking in the reciprocal cross. Southern's assumption is that the X chromosome breaks at the muscular dystrophy gene on the active member of the pair of X chromosomes, and that the sequence across the breakpoint should therefore lead directly to the relevant gene. (If the gene is not at the breakpoint it must be close enough to it to be inactivated as a consequence of the translocation.) To help overcome the difficulties of the direct approach, his group is also trying to produce a probe for human ribosomal genes that should help them in a specific case where it is the ribosomal genes from chromosome 21 that abut the broken end of the X chromosome as a result of the reciprocal translocation.

Lesh-Nyan is also an X-linked recessive disease but one in which the genetic lesion is known. It is the result of a deficiency of hypoxanthine-guanine phosphoribosyl transferase. However, according to C.T. Caskey (Baylor School of Medicine, Houston), there is seldom a lack of messenger RNA, presumably because the genetic lesion is usually a point mutation. Defects at the level of DNA have been detected in about half of the 28 families investigated but in no two cases are they the same. The optimal means of prenatal diagnosis of Lesh-Nyan disease is not yet certain but the use of restriction fragment

*The International Titisee Conference of the Boehringer Ingelheim Foundations on Impact of Modern Molecular Genetics on Human Biology and Medicine, was held on October 5–9, 1983.

THE International Titisee Conferences, held in Titisee in the Black Forest, have always been sponsored by the German company of Boehringer Ingelheim. Sponsorship used to come through their subsidiary, Dr Karl Thomae GmbH, but for the past year the new Boehringer Ingelheim Foundation, under its director Dr Hasso Schroeder, has taken over the job.

In addition to continuing to hold two or three Titisee conferences each year, the foundation has announced two other ways in which it will support basic research in medical sciences in the Federal Republic of Germany. First, it will sponsor an annual scientific lecture series in which the lecturer not only speaks at several academic centres but also spends a day or two at each as a consultant. Second, it will provide three types of grant. There are to be grants of one to three years for postgraduates working on basic clinical research projects; grants to industrial researchers, not necessarily in the pharmaceutical industry; and grants to cover trips of not more than sixty days to learn a technique or attend a conference.

The foundation has a budget of about DM 1.5 million (£0.4 million) this year and expects to have half as much again next year. Decisions are made by a board of trustees. □

length polymorphisms may prove to be best. Already this seems to be the case for phenylketonuria in which there may also be no consistent or readily detectable lesion accounting for the deficiency of phenylalanine hydroxylase (S.L.C. Woo *et al. Nature* **306**, 151; 1983).

Another, very elegant, use of restriction fragment length polymorphisms (R. White, University of Utah School of Medicine, Salt Lake City) showed that retinoblastoma is the result of development by at least two different mechanisms, of homozygosity for the mutant allele on chromosome 13 (see *News and Views* **305**, 761 and Cavanee *et al. Nature* **305**, 779).

It was left to D. Weatherall (John Radcliffe Hospital, Oxford) to address some of the practicalities of prenatal detection of genetic diseases based on the accumulated evidence of thalassaemias. For example, will the new technique of sampling chorionic villi in pursuit of first trimester diagnosis have an acceptable risk rate? It is too soon to know, said Weatherall. Why is clinical phenotype not always similar for one class of genetic lesion, making genetic counselling that much harder? Co-existent α-thalassaemia can sometimes dampen down the effects of homozygous β-thalassaemia, explained Weatherall, by way of example. Will prenatal population screening for genetic lesions ever be justified? Very rarely. But in the case of β-thalassaemia in Cyprus where 20–30 per cent of the population are carriers, 1–2 per cent of the children are homozygous and will die before reaching adulthood. In 95 per cent of the homozygous children the β-globin mutation is directly detectable and the co-existence of β-thalassaemia that reduces the risk of death from the disease can also be diagnosed. Here, there is a good case for prenatal screening of the population. □

Peter Newmark is Deputy Editor of Nature.

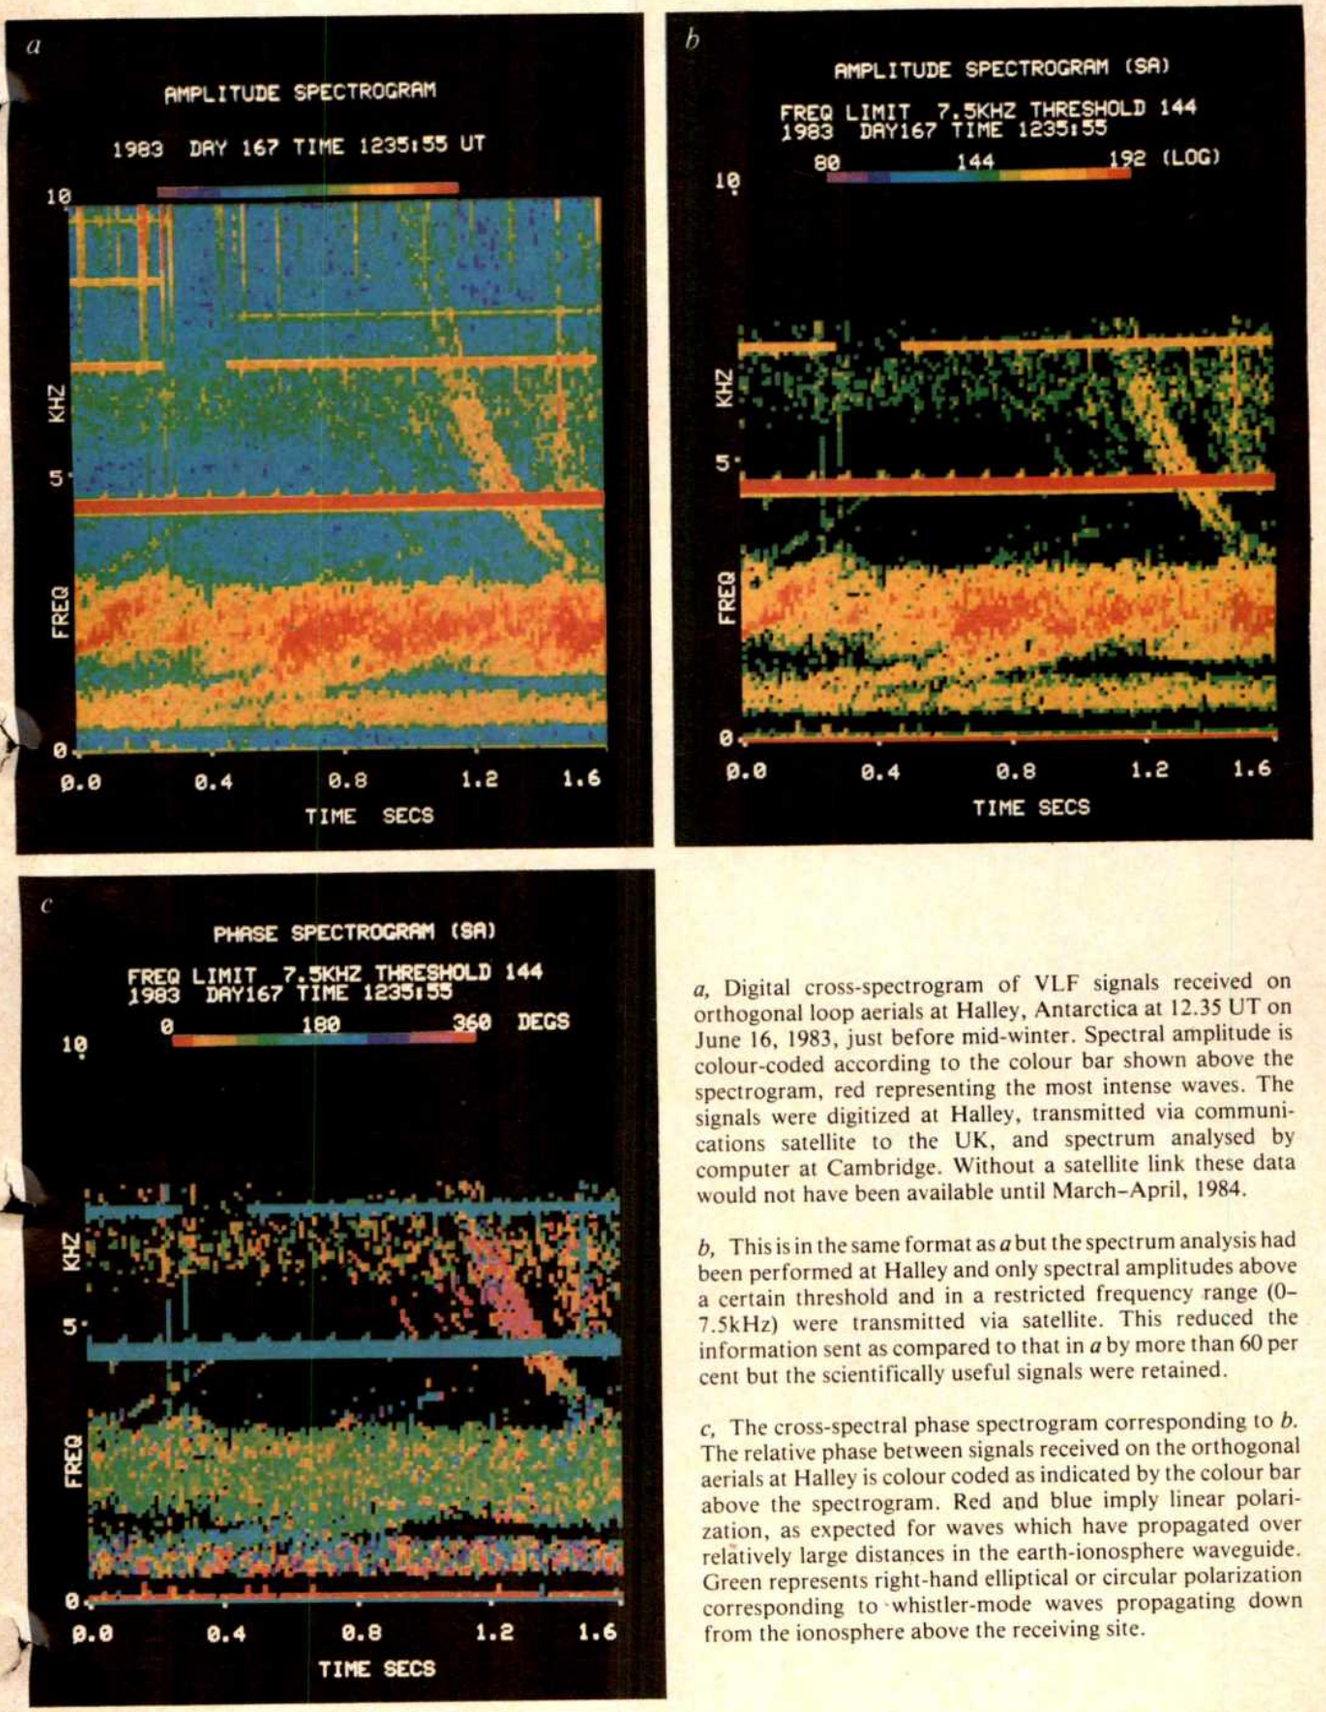
Space plasma physics

Antarctic research by satellite link

from Dyfrig Jones

WHAT do long term experiments in Antarctica have in common with experiments on scientific satellites? One obvious answer is their remoteness. And in what way do they differ? Data from satellites are available in real time and can even be analysed directly by dedicated computers on the ground, allowing scientists, or even the computers, rapidly to change how the experiment is operating. But data from experiments in Antarctica are usually stored on magnetic tape and collected once a year by ship — so producing a long delay between data acquisition and analysis, and an even greater delay before the experiment can be reconfigured. The delay is particularly frustrating in the increasing number of studies where satellite and Antarctic data are correlated in an effort to understand highly complex magnetospheric processes, because the spacecraft data have to be shelved until the Antarctic data arrive. Now, steps are being taken at the British Antarctic Survey, to overcome the problem, by transmitting scientific data from Antarctica to Cambridge via an INMARSAT geostationary communications satellite.

The space plasma physics section of the British Antarctic Survey (BAS) with the physics department, University of Sheffield, has operated VLF radio receiving equipment at Halley Station, Antarctica for a number of years. The main thrust of the research lies in the analysis of natural and man-made radio waves in the frequency range up to 10 kHz, the aim being to understand the generation and propagation of the natural waves and to determine what influence man-made waves may have on the magnetosphere. NASA's satellite Dynamics Explorer 1 is in an orbit admirably suited for correlative measurements with Halley, and a close collaboration exists between BAS and the Universities of Stanford and Iowa, and NASA. It greatly helps the project if the Antarctic data are readily available.



A satellite terminal was installed at Halley in January 1983. The first VLF data were transmitted to Cambridge in July. VLF wave experiments are highly demanding in terms of the amount of information that has to be acquired and telemetered. This is because natural waves, which occur randomly, may vary rapidly in frequency with time. To ensure that most significant events are captured, a wide band, typically 10 kHz, needs to be monitored continuously. Further, studies often require that the waves be recorded on more than one sensor. At Halley, two orthogonal vertical loop antennae are used, the minimum required for obtaining information on the waves' direction of arrival. If signals with a 10-kHz bandwidth are sent in digital form via satellite, 350,000 bits of information need to be transmitted for each second of data. For a bit-rate of 2.4 kbits s^{-1}, each second of data takes 2.5 minutes to transmit. Obviously, there is a strong financial incentive to decrease transmission time, and investigations are under way to see how this can be done without losing scientifically significant data.

On the ESA satellite GEOS, which carried a sophisticated wave experiment, a similar problem was resolved by incorporating a digital correlator on the spacecraft. This first computer in space calculated the auto- and cross co-variance functions of signals which, after reception on the ground, were Fourier transformed to produce dynamic spectra. The technique achieved a data compression factor of 20; this could have been increased with more powerful on-board processing. One technique being investigated using GEOS data by BAS, collaborating with the Laboratoire de Physique et Chimie de l'Environnement, Orleans, is the extraction of signals using cross-spectral phase information. The method is now being applied to Halley data, the preliminary results being shown in the figure. Signals from the orthogonal loops were digitized at Halley and despatched, without pre-processing, to Cambridge via satellite. Cross-spectral analysis was performed on the Cambridge IBM 3081 computer, the resulting spectrogram being shown in *a*. The constant frequency line near 5 kHz propagated from a VLF transmitter at the US station Siple. Intermittent lines at higher frequencies are due to navigation transmitters. The signals sweeping down from 10 kHz to 3 kHz are whistlers, that is, radio waves from lightning in the Northern Hemisphere which have propagated along the magnetic field line to Halley. The analysis of these gives invaluable information on plasma conditions out to 30,000 km from Earth.

The emissions below 3 kHz are natural waves produced in the Earth's magnetosphere. All the blue area is background noise. To remove this, the same data were pre-processed at Halley and only the spectral amplitude above a certain threshold was transmitted via satellite. The result is shown in *b*. Virtually all the signals visible in *a* are retained but the noise has been rejected; the maximum frequency was limited to 7.5 kHz. Figure *c* shows the corresponding cross-spectral phase spectrogram, the phase between signals on the orthogonal antennae being colour-coded. The relative phase of the waves from 1 to 3 kHz is as expected for a right-hand polarized wave propagating down from the ionosphere above the receiving site. The phases of the whistlers and the emissions below 1 kHz are different, implying that they have propagated to the receiver from a considerable distance in the Earth-ionosphere waveguide. Further computations will determine their direction of arrival.

These examples serve to illustrate not only the potential of satellite links for scientific research at remote stations, but also the importance of data pre-processing if the link is to be efficiently utilized. It should be added that the satellite link provides two-way communications and it is envisaged that experiments at Halley will be reprogrammed from Cambridge in much the same way as a satellite experiment is reconfigured by ground command.

Dyfrig Jones is Head of Space Plasma Physics, British Antarctic Survey, Natural Environment Research Council, Cambridge, CB3 OET.

a, Digital cross-spectrogram of VLF signals received on orthogonal loop aerials at Halley, Antarctica at 12.35 UT on June 16, 1983, just before mid-winter. Spectral amplitude is colour-coded according to the colour bar shown above the spectrogram, red representing the most intense waves. The signals were digitized at Halley, transmitted via communications satellite to the UK, and spectrum analysed by computer at Cambridge. Without a satellite link these data would not have been available until March–April, 1984.

b, This is in the same format as *a* but the spectrum analysis had been performed at Halley and only spectral amplitudes above a certain threshold and in a restricted frequency range (0–7.5kHz) were transmitted via satellite. This reduced the information sent as compared to that in *a* by more than 60 per cent but the scientifically useful signals were retained.

c, The cross-spectral phase spectrogram corresponding to *b*. The relative phase between signals received on the orthogonal aerials at Halley is colour coded as indicated by the colour bar above the spectrogram. Red and blue imply linear polarization, as expected for waves which have propagated over relatively large distances in the earth-ionosphere waveguide. Green represents right-hand elliptical or circular polarization corresponding to whistler-mode waves propagating down from the ionosphere above the receiving site.

Particle physics and cosmology

New light on heavy light

from John D. Barrow and R. R. Burman

DURING the past three years it has been extremely fashionable to consider the results of endowing the neutrino with a non-zero rest mass, and there now exists experimental evidence to suggest that this idea may one day pass from the realm of the fashionable to that of the factual[1]. However, while a small neutrino mass has dramatic consequences for astrophysics[2] it has a surprisingly small effect upon the structure of microphysical theories. This is because the neutrino does not mediate the weak interaction and hence the reciprocal of its mass does not determine the range of the weak force. If we choose to endow the photon with a non-zero mass the consequences will be more far-reaching: the masslessness of the photon is responsible for the infinite range and gauge invariance of the electromagnetic interaction.

Classical electrodynamics with a non-zero rest mass is described by the Proca equations[3,4] which reduce to Maxwell's when the photon mass (m_γ) is zero. These equations contain a characteristic length scale, $\lambda = \hbar/cm_\gamma$, and a small non-zero m_γ will lead to significant physical effects on the scale of the photon Compton wavelength λ. The length λ is an effective 'range' of the electromagnetic interaction here and static electric and magnetic fields will exhibit an exponential, $\exp(-r/\lambda)$, fall-off at distances $r > \lambda$ from sources. Other new features include a systematic variation of the velocity of light with frequency and a violation of Amperes law.

In an intriguing letter to *Nature*, Georgi, Ginsparg and Glashow[5] have resurrected the idea of a non-zero photon mass, but with a new twist. They suggest that in addition to the usual low energy symmetries $SU(3) \times SU(2) \times U(1)$ governing the strong, weak and electromagnetic interactions respectively, there exists an additional $U'(1)$ symmetry in nature, and oscillations occur between the different 'photons' which mediate the U(1) and $U'(1)$ interactions. This structure allows the 'ordinary' massless photon to obtain a mass, (see also refs. 6 and 7). The consequent classical electrodynamics would obey Proca rather than Maxwell field equations. This photon oscillation picture provides a natural scheme wherein a photon mass can enter, and is entirely analogous to the more familiar idea of neutrino oscillations. Georgi *et al.* point out some observational consequences that arise even if m_γ is so small as $\sim 5.10^{-18}$ eV/c^2. The oscillation of photons between cosmological relic distributions of the two kinds at 2.9 K (the measured temperature of the cosmic microwave background radiation) leads to small distortions from the precise Planckian spectral form that would arise if m_γ were zero. These distortions happen to be in the same sense and of the same magnitude as the purported spectral distortions measured by Woody and Richards[8] balloon-borne experiment in 1979. It is only fair to say that cosmologists have been wary of drawing any conclusions from the existence of these distortions because of their ambiguous statistical significance and the real possibility of systematic error. More exciting is the prediction of Georgi *et al.* that a definite sinusoidal variation of flux with wavelength should be observed shortward of 2 cm if the above spectral distortions arise from photon oscillations.

The photon mass level of 5.10^{-18} eV/c^2 required for measurable effects to exist is an interesting one. It is consistent with the observational[4,9] limits on m_γ obtained by direct experiments and all other limits obtained until the early 1970s which require only that $m_\gamma \lesssim 6.10^{-16}$ eV/c^2. However, there exist a variety of astrophysical limits on m_γ, which Georgi *et al.* do not consider, that appear to rule out a value so high as 5.10^{-18} eV/c^2 by a very wide margin. They all arise from detailed consideration of astrophysical objects in which magnetic fields, and hence the Maxwellian form of electrodynamics, play a key role in maintaining equilibrium or creating long-lived stable structures. Following a suggestion of Goldhaber and Nieto[4], Byrne and Burman[9] derived an upper limit of $\sim 3.10^{-20}$ eV/c^2 on m_γ by considering the electric current density and concomitant Joule heating in the interstellar medium. Barnes and Scargle[10] produced a similar limit from a study of what appear to be magneto-acoustic waves ('wisps') in the Crab Nebula. The existence of moderately dense, magnetized (1–2.10^{-5} gauss) interstellar gas clouds which appear to have contracted across the Galactic magnetic field, compressing flux, leads to an upper limit on m_γ of about 10^{-25} eV/c^2 in order that the repulsive Proca stresses do not overwhelm the effects of gravity and prevent collapse[9,11]. A similar physical effect would prevent the equilibrium of interstellar gas in the disc of our Galaxy unless $m_\gamma \lesssim 10^{-25}$ eV/c^2. Finally, it has been argued by Chibisov[12] that the magnetically-dominated interstellar plasma observed in the Small Magellanic Cloud would not exist in magneto-gravitational equilibrium unless the photon Compton wavelength, λ, which sets the effective range of the interaction, exceeds the characteristic field scale ~ 3 Kpc. This leads to a very restrictive upper limit on m_γ of about 10^{-27} eV/c^2. All these limits should be regarded as uncertain by about an order of magnitude numerically and each has associated experimental and theoretical uncertainties. We have

Table 1 Summary of limits on m_γ

m_γ limit	Site	Uncertainties
10^{-10} eV/c^2	Variation of light speed with frequency (terrestrial)[4,19]	Irregularity of medium in which light propagates; possible measurement error
5×10^{-12}	Dispersion of radiation from Crab pulsar[4,26]	Dispersion in interstellar plasma mimics the effect of photon mass
10^{-14}	Deviations from Coulomb's law (laboratory)[4,18]	
3×10^{-14}	Terrestrial Schumann resonances[20]	Cavity geometry
2×10^{-15}	Geomagnetic field variation on and near Earth[4,21,22]	Regularity of field; incomplete mapping of field; externally generated fields
4×10^{-16}	Pioneer-10 measurement of Jovian magnetic field[23]	Regularity of field; perturbation by external fields
2×10^{-16}	No low-frequency cut-off for hydromagnetic waves in the Earth's magnetosphere and solar wind[24]	Limited data; interpretation of a positive results could be non-unique
2×10^{-20}	Magneto-acoustic 'wisps' in Crab Nebula[10]	'Wisps' may not be magneto-acoustic waves
2×10^{-20}	Galactic magnetic field[4,9]	Properties and uniformity of interstellar medium
10^{-25}	Interstellar gas clouds[4,9]	Initial conditions in plasma that forms the gas clouds
10^{-25}	Interstellar gas in Galactic disc[4,9]	Regularity of field lines and plasma
10^{-27}	Interstellar gas in Small Magellanic Cloud[12,25]	Regularity of field lines and plasma; theory not presented in detail
10^{-33}	Smallest mass measurable in age of the Universe	

BOX 1: PROCA EQUATIONS

$$\nabla \times \mathbf{E} = -\frac{1}{c}\frac{d\mathbf{B}}{dt}, \qquad \nabla \cdot \mathbf{B} = 0$$

$$\nabla \times \mathbf{B} = \frac{4\pi}{c}\mathbf{j} + \frac{1}{c}\frac{d\mathbf{E}}{dt} - \frac{m_\gamma^2 c^2}{\hbar^2}\mathbf{A}$$

$$\nabla \cdot \mathbf{E} = 4\pi\rho - \frac{m_\gamma^2 c^2}{\hbar^2}\phi$$

A and ϕ are the space-time components of the 4-vector potential $A\mu$, **E** and **B** the electric and magnetic 3-vectors; **j** the current density; ϱ the charge density. The equations are not gauge invariant if $m_\gamma = 0$, and the Lorentz gauge ($d_\gamma A^\alpha = 0$) must be employed for consistency.

mentioned some of these uncertainties in a tabular summary of the experimental situation. It remains to be seen whether the huge superficial conflict between the astrophysical upper limits on m_γ and the value of about 5.10^{-18} eV/c^2 required for observable effects on the 2.9 K background can be side-stepped by a more rigorous scrutiny of the data and a wider examination of the theoretical alternatives.

One of the most interesting consequences of photon oscillations would be, as Georgi *et al.* remark, the striking fact that observations of what might be the lowest energy scale in nature, $m_\gamma \lesssim 10^{-18}$ eV/c^2, would tell us definite things about physics at ultra-high energies $\sim 10^{15}$-10^{19} GeV/c^2. In the last decade the most fruitful approach to the problem of elementary particles has been to follow the unified gauge theory idea to its logical and most elegant conclusion, namely the existence of a 'grand unification' of the SU(3) × SU(2) × U(1) symmetries of the strong and electro-weak interactions within a simple gauge group like SU(5), as first suggested by Georgi and Glashow[13] in 1974. However, if there exists a non-zero photon mass and an SU(3) × SU(2) × U(1) × U′(1) symmetry at low energy, then it is not possible for this low-energy behaviour to have resulted from the breaking of a single grand unified symmetry, like SU(5), at high energy. A proof of this result first appeared in a paper by Calogeracos, Dombey and Kennedy[14] and its truth is realized independently by Georgi *et al.* in their *Nature* letter. This theorem comes about on account of a fundamental difference in behaviour between a theory such as quantum electrodynamics (QED), which is invariant under the Abelian gauge group U(1) (the group under multiplication by complex numbers of unit modulus), and a theory such as quantum chromodynamics (QCD), which has a non-Abelian gauge group (SU(3) in the case of QCD).

Many years ago Stueckelberg[15] showed for QED that, even if the U(1) gauge invariance is broken by the addition of a small photon mass, the theory still exists and the limit $m_\gamma \to 0$ is smooth. Van Dam and Veltman[16], however, showed in 1970 that this was not the case for Yang-Mills theory (or SU(2)), which is the simplest non-Abelian gauge theory. Here, if the gauge particle is given a mass m, the limit $m \to 0$ does not produce the original massless theory (it is, in effect, a 'singular perturbation' of the massless theory). Dombey and Vayonakis[17] then showed that this peculiar behaviour arose from the existence of a longitudinal polarization state when the gauge particle possesses mass. In an Abelian theory gauge invariance causes this longitudinal mode to decouple when $m_\gamma \to 0$ (as it does in classical electrodynamics), whereas in a non-Abelian theory the gauge invariance is more complicated and, as a result, the longitudinal mode fails to vanish in the zero-mass limit.

In a hybrid theory, such as electro-weak SU(2) × U(1) or the SU(3) × SU(2) × U(1) × U′(1) proposed by Georgi *et al.*, the QED situation persists (because of the U(1) subgroup) and there can be an arbitrarily small photon mass. On the other hand, if electrodynamics were contained in a Grand Unified Theory such as SU(5) which, being a simple group, has no U(1) subgroup, then there would be no way of adding a small photon mass term within normal theories without violating charge conservation.

The discovery, therefore, of evidence for photon oscillations in the way suggested by Georgi *et al.* would be dramatic: not only would it show Grand Unification to be a false route towards understanding elementary particles but it would also compromise physicists' central article of faith — gauge invariance — as the most reliable guide to nature's ultimate structure.

Finally, it is worth pondering that a photon mass could well exist at a level below the reach of all direct experimental techniques, however accurate. The Heisenberg Uncertainty Principle gives the lowest mass m that can be measured in the age of the universe $T \sim 5.10^{17}$ sec as $m \sim \hbar T^{-1} c^{-2} \sim 10^{-33}$ eV/c^2 — surprisingly close to the strongest astrophysical limit on m_γ. Photons with a mass less than 10^{-33} eV would have a Compton wavelength greater than the size of the observable Universe, $cT \sim 1.5.10^{28}$ cm. Such incoherent quantum wave functions would, at the very least, shed new light on determinism. □

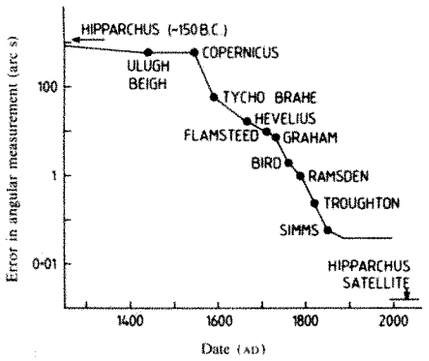
Astronomy

Astronomical angular accuracy

from David W. Hughes



PRACTICAL astronomy before the middle of the nineteenth century was mainly concerned with the measurement and cataloguing of the positions of stars and planets. Large-radius sextants, quadrants and circles were used. Accuracy was paramount, and depended on three main factors: accurate graduation of scales, careful alignment and skilful technique.

In many cases the quest for accuracy was fuelled by the demands of the theoretician. A typical example concerns stellar parallax. The Copernican insistence that the Earth orbited the Sun had the concomitant consequence that close-by stars should execute annual displacements as seen against the more distant 'fixed' stars. Proxima Centauri moves about 1.5 arc s because of this process. Three centuries elapsed between the prediction of this effect and its observation, when the craftsmen and astronomers and their instruments and techniques caught up in the 1830s.

The advance in angular accuracy is summarized in the figure, and the subject has been reviewed by Allan Chapman of Wadham College, Oxford in a recent edition of the *Journal for the History of Astronomy* (**14**, 133; 1983).

Three important developments in instrument-making were responsible for the changes shown in the figure. The first was introduced by Tycho Brahe. He augmented the normal radial scale divisions on the limbs of instruments by interspersing a series of diagonal lines. This enabled him to read the scale to a fraction of a degree whilst still retaining the small compact stable features of the instrument. Brahe also improved the sights of sextants and quadrants, thus eliminating most of the alignment errors.

Before 1660 angular measurement was

The observational error in the astronomical measurement of stellar and planetary positions plotted logarithmically against the year. The data have come from H. Mineur (see H.T. Pledge, *Science since 1500*, HMSO; 1939), A. Chapman (*J. hist. Astr.* **14**, 133; 1983) and *European Space Agency DP/PS(78)13*.

also limited by the 1-arc-min resolution power of the human eye. The adoption of the telescopic sight and the micrometer overcame this barrier and the angular error fell to 15 arc s by 1700 and 8 arc s by 1725. This made it possible to detect stellar aberration (small positional wanderings due to the vectorial addition of the velocity of light to the Earth's orbital velocity) and nutation (an 18.6-year wobble in the Earth's spin axis produced by the gravitational influence of the Moon and planets).

The third breakthrough came in the late eighteenth century. Instrument-makers Jesse Ramsden and Edward Troughton replaced the quadrant with the full circle. Circles could be rotated thus enabling the graduations to be cross-checked with micrometer microscopes. By 1800 the error had been reduced to 0.5 arc s. 1850 saw the installation of G.B. Airy's transit circle at Greenwich. Troughton and Simms were responsible for the optics and instrumentation. Six cross-checking micrometer-microscopes placed at 60° intervals around the circle gave a final accuracy of 0.06 arc s.

Unfortunately the accuracy of astronomical measurements of stellar position has only improved very slightly since then. The accuracy of the main applications of astrometry — the motions of the Moon and planets, the kinematics and dynamics of the galaxy, stellar mass determination and the rotation of the Earth and polar wandering — have also remained almost stationary. The next leap forwards will come from the ESA Hipparchus satellite. This is designed to measure stellar position to an accuracy of ± 0.0015 arcs and stellar parallax to ± 0.002 arcs. □

Archaeology

Setting Stonehenge straight

from Christopher Chippindale

FOR years the dismal state of Stonehenge, Europe's premier prehistoric monument, has been a disgrace — and an embarrassment to British archaeology. Always the most famous English ancient monument, it has become even more popular since archaeo-astronomers tried to identify it as a neolithic observatory. Yet many of its visitors, up to 800,000 annually, and two-thirds of them from abroad, find the place a sad let-down — hemmed in by busy main roads, approached through a nasty grey concrete tunnel, and each June the unwilling focus of an immense drug and rock music festival.

Partly it is a simple question of numbers. Stonehenge is rather a small monument — the central ruin with its three standing trilithons is only thirty-five paces across — and the grass there cannot survive the tramp of a million feet. Since 1978 the Department of the Environment (DoE), the government agency responsible, has closed the centre. Instead visitors are shepherded along a tarmac path, camouflaged a chemical shade of green, well away from the stones. In consequence it is impossible properly to see those features, the mortise-and-tenon joints of the lintels, the bluestone settings, the solar alignment of the axis, that make Stonehenge extraordinary and unique. And since aids for visitors are minimal, it is hard to know just what you should be looking out for.

The romantic ideal is to see Stonehenge alone, preferably by moonlight and with a storm brewing (it is still strongly recommended but is now very hard to manage). Over 200 years ago, William Stukeley, the first great student of Stonehenge, grumbled about its 'infinite number of daily visitants'. It was a famous shambles at Victorian bank holidays, with 'vanloads of uproarious humanity, dressed in all the colours of the rainbow, and in many others of aniline origin', and the dominant sound not lark-song but the crash of souvenir-hunters' hammers on the stones[1].

So great was the threat, during the 1920s, of a suburban sprawl of shapeless development — bungalows, cafés, an intensive pig-farm — crowding in on Stonehenge, that a public appeal bought 700 hectares of surrounding land and gave it to the National Trust, which would preserve Stonehenge for ever in a sweep of empty chalk downland. There were schemes to suppress the main A344 road which ran a couple of metres from the Heel Stone, so that the "circle itself seems almost submerged by the congestion, vulgarity, speed, and noise". But the road stayed open and soon spawned a car-park hard by the stones. (Calls for lavatories were at first resisted: "after all, the whole Plain is available for the convenience of the public".) Over the years, more facilities have grown on that site — extra space for cars several times, lavatories (both underground and up in the air), a café, souvenir shop, and bunker for the DoE's guardians — as well as a tunnel access-way to save the dangerous crossing of the road[2].

After four decades of such piecemeal growth, Stonehenge presents a classic case of how a cultural resource should not be managed. The main road across its edge is still open. The facilities are too close and too obtrusive, but because the site is cramped they are also inadequate. Management is bureaucratic and remotely directed from London, while the DoE shows no sign of imagination or initiative, or even of noticing the enormous advances being made elsewhere in managing and displaying historic monuments. It has suppressed the report of an independent working party[3] which recommended new facilities at a sensible distance and on a sensible scale. Instead it wants to enlarge on the present site, which is on the land bought by public subscription expressly to prevent tasteless development. The National Trust, recently bruised by a very public row over letting the air force develop a military bunker on another of its holdings, is, with every reason, declining to cooperate. And since the National Trust is the actual landowner, it has an effective veto.

In April 1984, the DoE will lose control over Stonehenge, which will pass to a new, autonomous Historic Buildings and Monuments Commission. Certainly, the new commission will know what a disaster it inherits — one of its commissioners calls Stonehenge today a 'squalid scandal' — and there is every hope it will abandon the fossil attitudes of the old regime.

The downs around Stonehenge contain, within a few square kilometres, an astonishing concentration of prehistoric sites[4], currently the subject of remarkable fieldwork by Julian Richards of the Trust for Wessex Archaeology. That ancient landscape, with its barrows, henges, cursuses and boundary earthworks, is the environment into which its builders put Stonehenge. A new policy for Stonehenge gives the chance of an imaginative scheme to show the place in that context — to set it once again, as William Stukely explained in 1740, "in clean and distinct areas, distant from profane buildings and traffic"[5]. □

The 1981 French–Chinese expedition to Tibet focused on the Lhasa block, extending earlier coverage 400 km north of the Tsangpo suture. The Lhasa block stood between 10 and 15° N latitude over most of the Upper Cretaceous and Eocene and, if Gondwanian in origin, had detached from Gondwana by early Permian. Seismic profiles reveal a complex Moho topography resulting both from multiple continental thrusting and large-scale strike-slip faulting. Subduction related granitoids representing mixtures of mantle and crustal components and anatectic granitoids have been analysed and dated. This study emphasizes the role of smaller blocks in the accretion of the continental mosaic.

A 3-year programme of French–Chinese cooperation for the study of Tibet and the northern Himalayas began in 1980. Preliminary results of the first campaign have already been published[1–4], and a second campaign, started in 1981, has yielded much additional data and has clarified several significant problems. The 1981 results have been discussed at a French–Chinese conference[5] and here we present a synthesis of the major results. Details of observations, laboratory measurements or modelling in each specialized field will be published separately. Some preliminary results from the 1982 campaign have been used when available.

We will summarize our results on a north–south cross-section, supposed to run from 28° to 32° N lat. not far from the longitude of Lhasa (Fig. 1). A geographical map of the area is shown in Fig. 2. Information gathered along trails which are perpendicular to the main trend of the section will be included whenever necessary. Observations start at the main central thrust (MCT) in the vicinity of Katmandu (Nepal) and extend northwards to the small town of Anduo, close to the administrative boundary between Xizang (Tibet) and Qinghai provinces.

Blocks and sutures

From a palaeogeographic standpoint, three blocks separated by two major suture zones have been recognized (Fig. 1). The Indus Tsangpo suture (ITS) marks the boundary between the Indian continent to the south and the Lhasa block to the north. The Lhasa block is in turn bounded to the north by the Bangong–Nujiang suture (BNS), with the Qangtang (or Tanggula) block lying to the north. On the basis of earlier work[6], at least two other sutures, the Kokoxili (KS) and Chilien (CS) sutures, can be recognized farther north, before reaching the Tarim basin (Fig. 1). The four sutures will be labelled ITS, BNS, KS and CS with increasing age from south to north. The identification of three blocks and two sutures in southern Tibet has been proposed by Chang and Cheng[6] and has been corroborated by further work, including French–Chinese work in 1980 and 1981[1,2,5]. The key observations for such a distinction are stratigraphical and are summarized in Fig. 1. We present here additional constraints provided by new data.

Earlier palaeomagnetic results for the Lhasa block come from the Middle to Upper Cretaceous Takena formation (red beds and Orbitolina limestones) and the Lingzizong volcanic formation of Palaeocene to Eocene age, in the vicinity of Lhasa[4,7]. The authors concluded that the Lhasa block stood at a latitude of 20° N 90-Myr ago and at 10° N 65-Myr ago. Our results confirm only (and partly) the second of these results. During the 1981 mission, sampling has been extended north to Anduo. Laboratory measurements on 18 sites in Takena red beds revealed a multicomponent magnetization. A pre-folding stable component can be confidently isolated, with positive fold tests at a confidence level higher than 99%. Palaeomagnetic data do not indicate any significant latitudinal movement within the Lhasa block, suggesting that it formed a single unit before folding of the Takena formation (around 70 Myr ago?). Although it cannot as yet be demonstrated whether this magnetization is primary or a remagnetization acquired just before folding, the fact that all sites show a normal polarity suggests that magnetization was acquired before 80 Myr, the end of the Cretaceous Long Normal Interval. The corresponding palaeolatitude of Lhasa, possibly as late as 80 Myr, is 12° N. At the same time, the northern margin of India may have been between 20 and 30° S. Results from nine sites in the Palaeocene–Eocene Lingzizong formation indicate a palaeolatitude close to 15° N. Very few precise isotopic ages are available for the Lingzizong formation[7,8]: they are a $^{40}Ar/^{39}Ar$ age of 60 Myr on an andesite and a K–Ar age of 48 Myr on an ignimbrite. Thus it appears that the Lhasa block remained approximately stationary in latitude for a period that extended at least from 80 to 60 Myr and may have been as long as from 100 to 48 Myr. Since the suturing of India to Asia, the block has moved about 20° north.

The most significant piece of new palaeontological information is given by fossil plant remains from the Takena formation. Immediately north of Lhasa, but also further north near Lake Peng-Co, close to Barda, new species of silicified woods

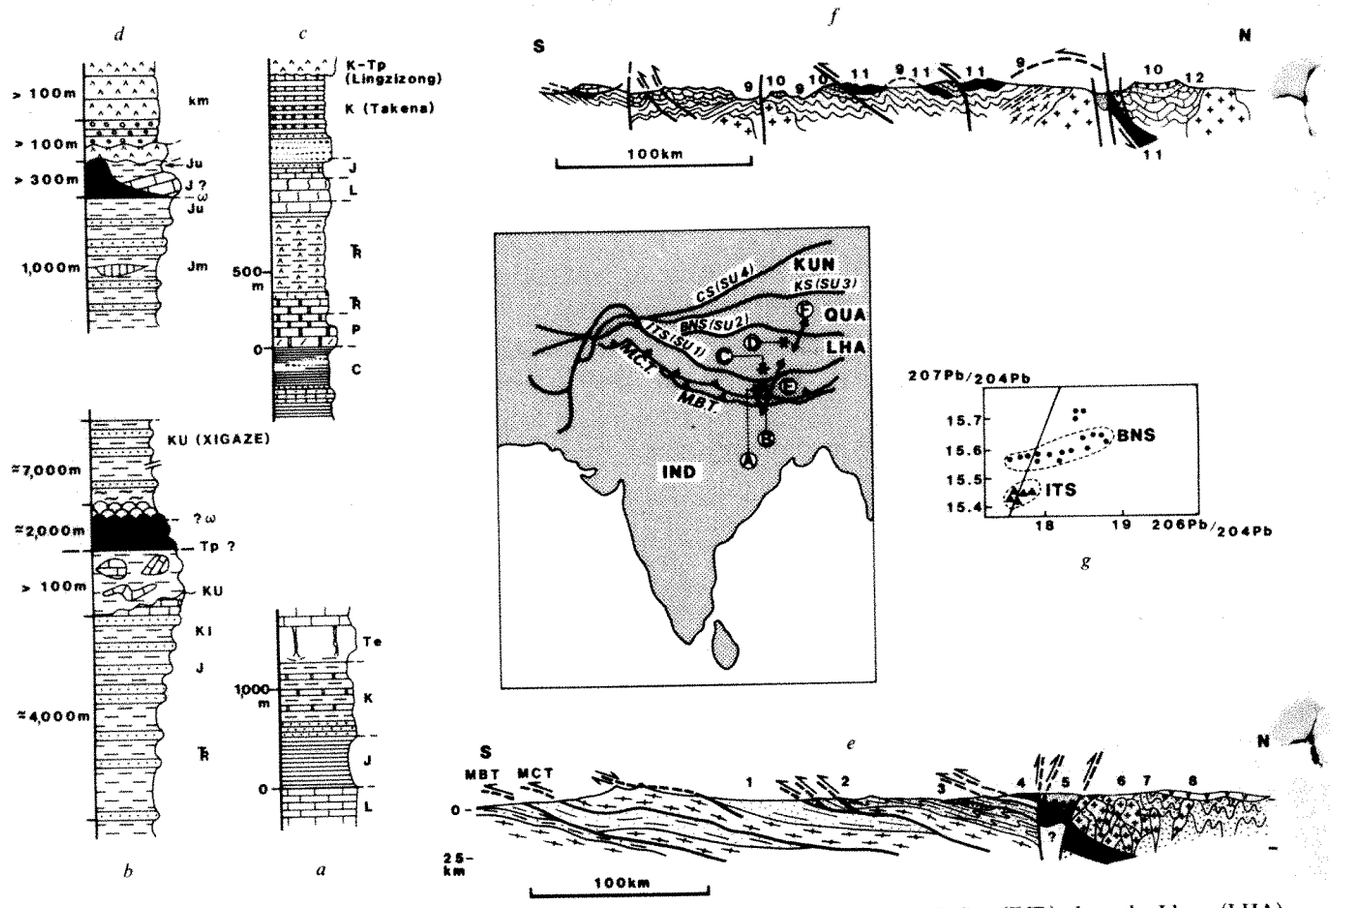

Fig. 1 Major tectonic blocks and boundaries in the Tibet–Himalaya. From south to north are the Indian (IND) plate, the Lhasa (LHA), Quantang (QUA) and Kunlun (KUN) blocks and the Asian (ASI) plate and the main boundary thrust (MBT), main central thrust (MCT) and Indus Tsangpo (ITS or SU1), Bangong Nujiang (BNS or SU2), Kokoxili (KS or SU3) and Chilien (CS or SU4) sutures. Stratigraphical sections from the southern (*a*) and northern (*b*) parts of South Tibet and from the southern (*c*) and northern (*d*) parts of the Lhasa block (see ref. 1 for details of sections *a* and *c*). *e*, Schematic cross-section through the ITS (see also ref. 37). 1, South Tethyan series (Indian shelf sediments); 2, North Tethyan series (Triassic and Jurassic of the Indian continental rise); 3, Upper Cretaceous or Palaeocene (?) wildflysh; 4, ophiolite series; 5, Xigaze group flysh; 6, Gangdise plutonic belt; 7, folded Mesozoic series of the Lhasa block (including Takena red beds); 8, Lingzizong volcanic formation; *f*, schematic cross-section through the BNS; 9, Middle to Upper Jurassic flysh and slates; 10, Middle Cretaceous volcanics and red series; 11, ophiolite series; 12, Jurassic limestone and slates. *g*, Lead isotope diagram for the ITS magmatic section (triangles) and BNS (circles) ophiolites. The isotopic composition of the three points above the main field of the Donqiao ophiolite is due to alteration processes. The reference line is the geochron.

belonging to the genus *Protopodocarpoxylon* (gymnosperms, Cheirolepidiaceae) have been discovered that are always associated with Albian orbitolinids. This genus, which is widely represented in the Lower Cretaceous of western Europe, northern Africa and south-east Asia, has never been recorded in India or other south-Gondwana areas. Its distribution seems to fit palaeolatitudinal boundaries between 0 and 35° N. All the numerous fossil woods sampled from the Lhasa block show the presence of growth rings suggesting a palaeolatitude not too close to the Equator during Albian and Aptian times, in agreement with palaeomagnetic results. Our observations confirm previous work[9].

The discovery of abundant palynomorphs in a level from the latest Triassic (Rhaetian) north of Lhasa suggests that an equatorial or tropical latitude was reached by the Lhasa block as early as late Triassic. The flora indicates very close relationships with the equatorial (and north equatorial) province and lacks any significant Indian taxa. Most of the taxa are commonly found in Europe and the Caucasus and more recently in Szechuan province[10]. The latter find suggests that not only the Lhasa block, but also the south Chinese block were situated near the Equator or not far from the tropical area as early as late Triassic[11,12]. Somewhat surprisingly, there seems to be no unambiguous palaeontological proof of the Gondwanian origin of the Lhasa block as doubts can be cast on the significance of the Damxung–Linzhu tillites. Examination of these 'tillites' is not sufficient to demonstrate that they are a glacial sediment or alternatively rift infill. If they are indeed late Carboniferous glacial tillites, they imply a climate and latitude in striking contrast with the early Permian climate and latitude implied by the Cathaysian flora which has been discovered in the Lhasa block, and which does not contain a single Gondwanian element[9]. This indicates that if the Lhasa block indeed originated as a Gondwanian microcontinent it had detached from Gondwana as early as early Permian.

The tectonic environments of the ITS and BNS sutures are quite distinct. To the north of the ITS, the southern part of the Lhasa block can itself be divided into three zones[1,13]. North of the Gangdise (Transhimalayan) plutonic belt, a Precambrian continental basement and its Mesozoic cover have been tightly folded in the Cretaceous with east–west trends and vertical cleavage[1,14,15]. Within the southern part of the Gangdise belt, amphibolites, meta-pillow lavas and meta-cherts may be associated with a meta-ophiolitic suite. A thin Triassic to Lower Cretaceous sequence with low metamorphic grade occurs to the south of Lhasa. This sequence displays at least three phases of deformation: small scale (<10 m) isoclinal folds (north–south stretching lineation, slaty cleavage (S1) with southward vergence, increasing in intensity towards the ITS) are followed by a second phase, with larger (>100 m) folds (fanlike cleavage (S2) and vertical axial planes with undecided vergence). However, no unconformity which would allow precise separation of these two phases has been observed and they may be pulses of a single event. The second phase was over when the

uncomformable Lingzizong volcanics were deposited. Tectonic and stratigraphical observations suggest that the Gangdise belt intruded a continent–ocean margin, leaving remnants of continental crust to the north and of (Triassic?) oceanic crust to the south. The associated Lingzizong volcanics, which span possibly from the Palaeocene to recent times[7,8], have themselves undergone a third phase of crustal shortening, with long wavelength folds, and both high and low angle thrust faults with small (less than a few kilometres in size) displacements.

South of the crystalline Gangdise belt, the Xigaze series may be both transgressive on the plutons to the north, and conformably deposited on the Tsangpo ophiolites to the south. The bulk of the Xigaze group consists of a thick turbidite sequence earlier thought to represent a fore-arc basin (see refs 1, 14). It has suffered east–west folding with clear southward vergence and exhibits steeply dipping cleavage and shortening of at least 30%. The ophiolite sequence on which the Xigaze formation rests has been described by Nicolas *et al.*[3]. Using radiolaria, Marcoux *et al.*[16] have determined an age of 110 Myr for the cherts overlying the pillow lavas. Although a complete sequence from the pillows and radiolarian cherts to the Xigaze series has been observed near Tiding[16], ophiolitic massifs are generally bounded by thrust or strike slip contacts and are intensely deformed. New (1982) observations have revealed important tectonic zones within the Xigaze formation and throw doubt on the previously suggested continuity of this formation between the batholith and the ITS ophiolites[1]. It has already been pointed out that a very late compressive phase, postdating the Oligo-Miocene(?) Liuxu conglomerate, has in some places led to a northward backthrusting of the ophiolites. The tectonics of the Upper Cretaceous (?) mélange, Triassic flysch and autochtonous Indian series south of the ITS involve four shortening phases, with intense isoclinal folding and southward thrusting and symmetrical folding with steeply dipping cleavage and varying vergence between the Upper Cretaceous and the Eocene[1]. This complex history of superimposed deformations may be consistent with an Upper Cretaceous to Palaeocene southward obduction of the ophiolites on top of India (see ref. 37). Alternatively, it could be related to progressive deformation within an accretionary prism at different depths. Post-Eocene deformation is mostly related to strike-slip faulting.

The tectonic style of the BNS is rather different. The suture zone has been studied in particular near Anduo and between Gyanco and Donqiao. There, an ophiolitic nappe is thrust over a thick series of Middle to Upper Jurassic sandstones and black slates. This series is locally strongly folded, slightly metamorphosed and displays a steep cleavage with variable dips both to the south and to the north. The ophiolites are in turn locally tectonically covered by a metasedimentary nappe of Palaeozoic (?) rocks. All these units are uncomformably overlain by a Middle Cretaceous volcanic and red detrital formation. These formations have undergone isopaque (constant thickness) folding, with N140° axes, show a cleavage with undecided vergence, and thrust faulting accompanying late emplacement of the ophiolites on the red beds. Although the ophiolites have been severely deformed, they exhibit all the traditional components of the suite (pillow-lavas), a sheeted dolerite complex overlying garnet-bearing amphibolites, isotropic to layered gabbro, troctolites, wehrlites to dunites and serpentinized residual harzburgites containing chromite rich bodies. The ophiolites have been reworked in a grey neritic limestone of Upper Jurassic age. Moreover, in Donqiao, the ophiolites seem to be covered in turn by a transgressive marine detrital Upper Jurassic to lowermost Cretaceous series.

The Quangtang block, north of Anduo, is less well known, as observation there was far less extensive. It seems to involve rather simple, broad, folding of dominantly neritic Jurassic sediments. Rapid surveys and inspection of the geological map of China seem to indicate that plutonic and volcanic formations are far less abundant to the north of BNS, which, of course, raises questions as regards the polarity of the former subduction zone. A southward dipping subduction would be favoured by the scanty presently available data, opposite to what was previously thought (see ref. 6).

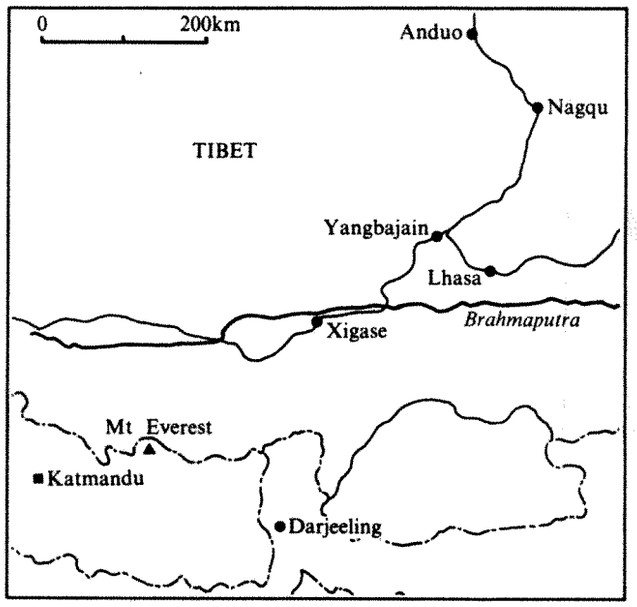

Fig. 2 Map showing the relationship of southern Tibet to the Himalaya. The place names given are those used by the French–Chinese three-year geoscience cooperation programme.

The analysis of lead isotopes in samples of ophiolites from the ITS and BNS sutures reveals striking differences (Fig. 1). The Pb isotopic composition of the magmatic sequence from ITS falls in the field of dredged samples from the Indian Ocean Ridge[18]. This may indicate a genetic relationship between the sub-Indian Ocean mantle and the ophiolites. A U–Pb total rock age of 119 ± 25 Myr has been obtained from the magmatic section of the ophiolite near Xigaze. In contrast, rocks from BNS show higher 207/204 ratios and resemble ophiolites from the eastern Mediterranean[19]. This is compatible with the Bangong-Nujiang ophiolites have formed in a small back arc or interarc basin, as indicated by the palaeolatitudinal studies reported above.

The ultramafic part of the Tsangpo ophiolite has an isotopic signature that is similar to that of the Donqiao pillow-lavas with higher 207/204 ratios than in the magmatic section. This suggests that the two parts of the Tsangpo ophiolite may not be cogenetic.

The volcanic environment of the two sutures is also contrasted. Volcanic rocks are very abundant in the south of the Lhasa block. They occur as ignimbritic tuffs in the Middle Cretaceous Takena formation and form most of the 1,500-m thick Lingzizong formation, with piles of andesite flows and rhyolitic ignimbrite flows. This thick calc-alkaline sequence contrasts with the less abundant mostly basic volcanic rocks of BNS. Only a few ignimbrite flows are observed there. In Nagqu, volcanic rocks overly the black Jurassic slates and seem to postdate the Cretaceous red beds in Anduo. These red beds are sometimes thrust over the basalts and andesites. Thus, the volcanic environments of ITS and BNS appear to be suggestive of Andean and island-arc subduction respectively, although the age of the northern volcanics remains to be determined.

Plutonic rock and basement gneisses have been sampled in a fairly systematic way to obtain geochronological data (U–Pb: accessory minerals) and to identify the source regions of the granitoid magmas (Nd, Sr and Pb initial isotopic compositions). The ages at which the basement material was transformed into gneisses, although poorly defined because of the heterogeneity of the inherited Pb components, appear to be synchronous with the plutonic activity. Inherited Pb-components in zircons yield

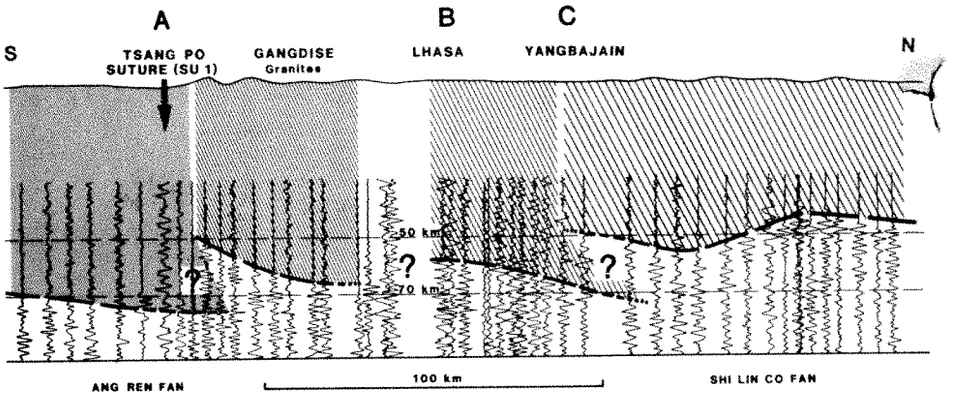

Fig. 3 Wide-angle seismic refractions from the Moho along the section shown in Fig. 2 reveal a complex Moho topography (after refs 20–22). First arrivals are picked at the dashed lines, providing the Moho topography. Particularly noteworthy are the 20-km step in the Moho near ITS and the presence of two superimposed Mohos at the latitude of Yangbajain. The profiles result from two shots in Angren and the Shi Lin Co (about 100 km outside of the figure to the west) recorded in fans along the main road from Quxu to Nagqu. No vertical exaggeration.

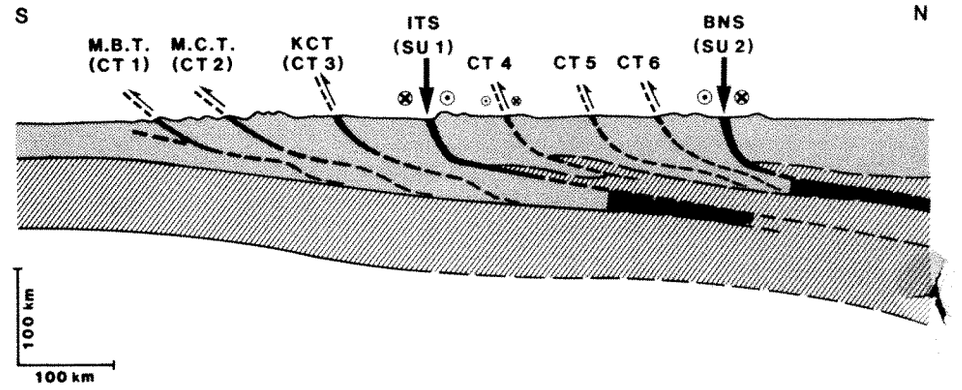

Fig. 4 A model for the structure of the lithosphere in the Tibet–Himalaya. The role of obduction related sutures (Indus Tsangpo suture or ITS, Bangong-Nujiang Suture or BNS) and of continental thrusts on the Indian plate (main boundary thrust, main central thrust, Kangmar thrust labelled CT1 to CT3) and in the Lhasa block (CT4 to CT6 corresponding to possible thrusts near Yangbajain, Gulu and South of Anduo) is emphasized. Continental and oceanic crusts are shaded in light and dark grey respectively. The subcrustal lithosphere is ruled. Older sutures and continental thrusts are rotated into the vertical and reactivated as strike-slip faults.

minimum ages up to 2,200 Myr in the Everest area and also Precambrian ages in the Yangbajain and Anduo areas. Clearly, all crustal blocks are made of old basement materials. The leucogranites of the High Himalayas, and those intruding the Tethyan sediments further north, yield ages of 15–30 Myr and seem to be purely anatectic. The Gangdise plutonic belt comprises numerous bodies of gabbro, diorite, granodiorite and granite which have been intruded from 95 to 40 Myr ago. Initial Nd, Sr and Pb isotopic compositions show large heterogeneities and plot along trends interpreted as a mixture of mantle-derived component(s) with continental crust materials. The volcanic rocks of the Lingzizong formation have the same isotopic characteristics implying a similar origin. In both cases, the crustal components appear to be dominant. Farther north, the Yangbajain, Gulu and Anduo granitoid belts yield ages around 50, 100 and 100 Myr respectively. The Pb-isotopic composition of these rocks is compatible with an origin by partial melting of the basement materials. From the point of view of geochemistry, the Gangdise belt looks like a subduction related complex built on continental crust, similar to the Sierra Nevada batholith, whilst other intrusives farther north in Tibet are anatectic granitoids.

Thus, the available information suggests that the ITS corresponds to an Andean subduction environment, which has been terminated between the Upper Cretaceous and the Eocene by the collision of India with the Lhasa block, acting as the southern margin of Asia. On the other hand, the BNS is different and a likely interpretation at this stage involves an island-arc subduction environment, which has been terminated in the Upper Jurassic to Lower Cretaceous by a collision between the Lhasa block and the Quangtang block, then the southern margin of Asia.

Crustal repetition

A 300-km long north–south seismic section has been obtained by Hirn *et al.*[20–22], using critical reflection profiling on the Mohorovicic discontinuity, complemented by fan profiles. The detailed data and interpretation are given elsewhere[20–22] and only the major features are summarized here (Fig. 3). The section reveals a thick crust (between 50 and 70 km) with a complex structure. An outstanding feature is a 20-km step in the Moho precisely below the surface trace of the ITS which is consistent with strike-slip reactivation of a major thrust contact. The data do not allow resolution of whether or not the Lhasa block is actually underlain by Indian crust. Crustal repetition occurs along parts of the section, particularly north of Yangbajain: there two superimposed Mohos are observed with the lower crustal member being ~20 km thick. Another 20-km step in the Moho, very similar to that observed below the ITS has been found near Anduo below the BNS (outside of the range of Fig. 4, see refs 20–22). Thus, the Tibetan Moho displays a complex topography with slopes and faults and in places implies crustal repetition (although the two crustal members are not necessarily complete) by continental thrusting.

It is now widely accepted that the structure of the High Himalayas is associated with a major intracrustal thrust, the MCT, with the northern Himalayan crust thrust southwards. The throw on the MCT is not yet known but may be very large. It seems that the MCT is no longer the active thrust but that tectonic activity has jumped southward, with a new continental (crustal) thrust, the MBT, presently active[23–25]. Intense shear along the MCT within the lower structural levels of the Tibetan slab is linked with the genesis of the 20-Myr old anatectic Himalayan leucogranites. A detailed field study of the Lhozag–Kangmar–Lhagoi–Kangri belt of granite plutons, about 100 km to the north of the High Himalayas[26], also implies that a major continental thrusting episode occurred there, possibly leading to crustal thickening, and associated with a high grade metamorphic episode contemporaneous with thrusting on the MCT (around 20 Myr).

The gneisses around Yangbajain, about 100 km north of the ITS, have a Precambrian primary age but have undergone a young metamorphic episode at around 50 Myr. This is also the age of the Yangbajain anatectic granites. The U–Pb systematics of zircons imply that these gneisses have been formed at a depth of ~15 km. They may have been thrust over the Cenozoic Lingzizong volcanic formation and thus be related to another intracrustal fault with 15 km of vertical offset. It may be sug-

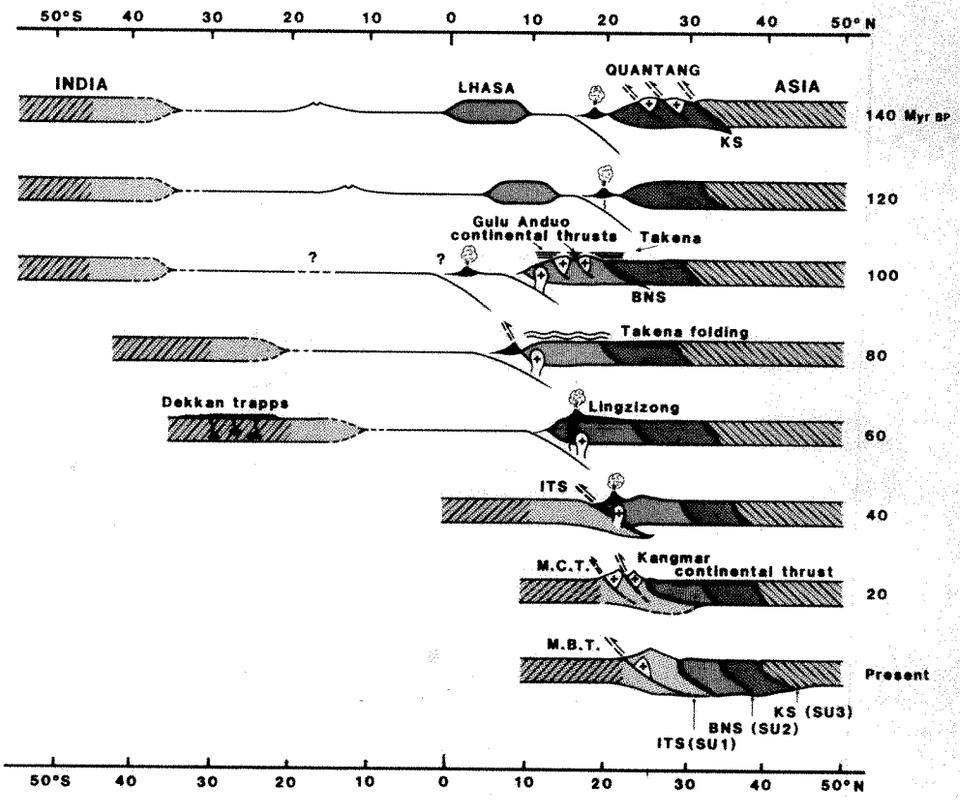

Fig. 5 An attempt to reconstruct the evolution of the Lhasa block in relation to the Indian and Asian continents since the beginning of the Cretaceous, at 20-Myr intervals. The blocks are located in latitude in agreement with palaeomagnetic (after 100 Myr) and palaeontological (before 100 Myr) data. Shortening of the Lhasa and Quantang blocks by a factor of two and of the northern margin of India by about 1,000 km have been included. Closing of sutures, activation of continental thrusts and related granite formation, Takena deposition and folding and Lingzizong volcanic activity have been emphasized. Controversial aspects are, of course, present such as the origin of Takena folding by collision with an island arc (see text for another possibility).

gested that the genesis of granitoid rocks in Tibet is related to large-scale intracontinental thrusts (leading to crustal doubling or thickening) and that, for instance, the Gulu and Anduo belts are the signature of older (100 Myr old) thrusting events. This would be a major means of crustal thickening in Tibet: a picture emerges where two sutures, both related to major continental collisions, separate thickened continental blocks in which thickening (crustal repetition) is related to as many as six major thrusts (MBT, MCT, Kangmar, Yangbajain, Gulu, Anduo from south to north; see Fig. 4). These continental thrusts might result from post-collisional continuing convergence.

Some of the authors of this article are, however, reluctant to accept Yangbajain as the site of a major southward verging Tertiary intracontinental thrust. Some structural observations show that between Yangbajain and Nagqu deformation of late Mesozoic to Cenozoic age is characterized by steep cleavage dipping mostly south and, locally, horizontal stretching lineations, and thus presumably indicative of large scale strike slip motion, dominantly in an east–west direction. The relative importance of thrusting and strike slip faulting with respect to crustal shortening in Tibet has yet to be analysed in detail.

Kinematic evolution

The stratigraphical and tectonic observations, together with the isotopic age determinations and palaeomagnetic data reported here allow us to propose a geodynamical model for the evolution of blocks which are now part of the Indian–Asian continent over the past 120–140 Myr. The time and space distribution of our data is, of course, still far from complete and the interpretation that we propose is not unique at all periods. The present model (Fig. 5) includes the possibility of lithospheric shortening by continental thrusting and is controlled in latitude by palaeomagnetic and palaeontological data. It begins around 140 Myr ago. The Quangtang block was sutured to Asia along the Kokoxili suture ~200 Myr ago and some crustal shortening may subsequently have occurred on (hypothetical) continental thrusts. Around 140 Myr ago, a small ocean basin between the Quangtang and Lhasa blocks closed along the BNS (its size at 140 and 120 Myr has been exaggerated on Fig. 5). Continental shortening followed along the Gulu and Anduo thrusts and continental red beds were deposited over this southern margin of the Asian continent. Folding of the red series may have occurred around 80 Myr or later. Its origin is still puzzling and it may either be due to interaction with a hypothetical island arc (which would have to have been completely obliterated subsequently), or be linked with the subduction process (Andean folding) or be related to the obduction and collision themselves. At this time, the Lhasa block was at low latitudes. The Lingzizong arc volcanics were erupted between 60 and 45 Myr, at which time the subduction zone was blocked and obduction occurred along the ITS. Continental shortening then occurred in the Yangbajain (40 Myr), Kangmar and MCT areas (20 Myr), recently jumping to the MBT. An unknown length of Indian continental lithosphere may also have been thrust under the MCT. Our schematic representations suggest that it may be up to 1,000 km long as suggested by Argand in 1924[27].

Geodynamical consequences

Our observations have important geodynamical implications: first, they may provide constraints on the mechanism of continental accretion and evolution, second they can tell us something about the driving mechanism of plate tectonics.

We have suggested that there may be as many as two continental collisions and six continental thrusts between 26 and 33° N at the longitude of Lhasa. There are two more collisions (suture zones) and possibly several continental thrusts north of the area that we surveyed, between 33 and 40° N. Each one of these tectonic features leads to the disappearance of some continental surface, to crustal thickening and to high elevations. As time passes, erosion will destroy high mountains and plateaus, thin the crust and bring it back to its 'normal' 35-km continental thickness. In the process, continental crust will have been removed not only along horizontal dimensions (surface area) but also along the vertical dimension (volume loss). The eroded material will, of course, be redeposited elsewhere, although much of it is likely to be returned to the mantle in nearby active subduction zones. A very quick and crude estimate of the surface and volume loss in Tibet over say, the past 150 Myr can be made: over a 2,500 km long front, from the Pamir to the Assam syntaxis, blocks that now extend over 1,500 km from north to south with a double continental crustal thickness may have originally extended over as much as 3,000 km. The total surface

loss is of the order of 4×10^6 km^2 (or between 2 and 3×10^{-2} km^2 yr^{-1} in average surface loss) and the final volume loss will amount to over 100×10^6 km^3, or between 0.5 and 1 km^3 yr^{-1} on average. It is interesting to compare this value with the rate of possible sediment loss in subduction zones, which is of the order of 1–2 km^3 yr^{-1} (taking average sediment thickness, length of trenches and subduction velocity of 0.5 km, 40,000 km and 5 cm yr^{-1} respectively). Thus, continental collision acts as a significant limiting factor for continental growth (which is itself related to volcanic and plutonic activity in subduction zones).

Nevertheless, continental collision has enlarged the Asian continent by adding allochtonous continental fragments to it. The older sutures are the remnants of continental collisions related to previous accretion of allochtonous blocks to Asia since the beginning of the Palaeozoic[6]. The situation encountered in western North America[28] is reminiscent of what we observe in Tibet. The origins of each individual block may be quite diverse, as shown by the analysis of faunas and floras. The Lhasa block for instance is a Cathaysian block and not necessarily of Gondwanian origin. Together with much of Indochina, the Lhasa block may have been part of Pacifica[29]. Thus the Asian continent actually results from the juxtaposition of many blocks of diverse origins and is a typical continental mosaic.

The sutured edges of previously accreted continental blocks will induce large-scale heterogeneity and anisotropy of deformation when a new block is accreted through collision. Those earlier sutures which are favourably oriented with respect to the principal compressive stress due to the new collision will be reactivated, often as large strike-slip faults[30]. Some of the major strike-slip faults described by Tapponnier and Molnar[31] in Tibet are rejuvenated sutures. This is the case for large segments of most sutures described here. It is also true for other parts of China, and in Tibet for several continental thrusts (such as the ones near Yangbajain and Gulu, for instance). However, active faults resulting from a collision need not necessarily all be reactived block boundaries: the most efficient way to join two reactivated strike slips faults may in cases be to create a new fault through some particular block in the mosaic. Still, an active tectonic phase is in some ways guided by tectonic features resulting from previous phases. If the mode of accretion of the Asian continent is to be regarded as the rule rather than the exception for continental accretion, then earlier continental collisions are important in establishing the tectonic grain of a future continental collision.

Following the work of Forsyth and Uyeda[32], many authors have considered the pull of descending slabs at oceanic subduction zones as the main force acting to drive plate motion. Other forces, such as the so-called 'ridge push', gravity sliding and shear coupling to the asthenosphere have been regarded as less important and in any case not resolvable. However, it seems clear that slab pull cannot be the leading force in the case of the relative motion of the Indian plate with respect to Asia. Subduction along the ITS stopped at least 45 Myr ago and since then, there has been no oceanic lithosphere left between India and Asia. Continuing slab pull beneath Java and Sumatra is not likely to be sufficient to counteract alone resistance to convergence in the Himalayas. Yet, intracontinental motion continues on the MCT and Kangmar CT around 20 Myr, and now on the MBT, at a rate of about 2 cm yr^{-1} (ref. 33). The total motion between India and Asia is 5 cm yr^{-1} (ref. 31).

Continental shortening is also taken up along sets of large strike-slip faults[31,34]. Models of continental delamination (see ref. 35) cannot account for the continued penetration of India either, and other boundary forces must be sought. The northward motion of India lasted since the Jurassic and the subcontinent was subjected to considerable tensile stress from maybe as early as 110–60 Myr ago when the Dekkan traps were produced. Recent geochemical analyses suggest that the traps result from the fusion of the continental lithosphere and do not involve deeper components[36]. This observation seems difficult to reconcile with any significant contribution from the ill-named 'ridge push' force. Moreover, before India was rifted away from Gondwana, other continental fragments, rifted earlier either from Gondwana or elsewhere, were already 'attracted' towards Asia in a dominantly northward direction and collided with it[30].

Thus, there is a long history, probably more than 200 Myr long, of polarized accretion of blocks to the southern margin of the Asian continent. A similar long-lived polarization of motion is suggested by the study of allochtonous terranes accreted to North America and sheared along the San Andreas–Denali strike-slip system (see ref. 28). These observations seem to imply the persistence over several hundred million years of large-scale convection currents, more or less stationary with respect to the mantle, and coupled to the lithosphere. A possible mechanism is gravity sliding over the hot ascending limb of such a large convection cell. The initial breakup of Gondwana, the motion of small blocks and then of India, the successive collisions and present continental shortening would thus all be due to northward gravity sliding over a large hot mantle zone lasting at least 200 Myr. This zone may well correspond to the Atlantic–African geoid high, as recently argued by Anderson[17]. The trend of the southeastern part of this geoid high, associated with the Réunion, Kerguelen and Crozet hotspots, is compatible with the observed direction of polarized motion, that is perpendicular to it.

This work was carried out within the Cooperative Research Project of the Chinese Geological Academy, Chinese Academy of Sciences, French Centre National de la Recherche Scientifique and Institut National d'Astronomie et de Géophysique. This programme benefited greatly from the help of the French Ministère des Affaires Etrangères, and the Service des Relations Internationales of the CNRS. Special acknowledgments go to G. Aubert, J. Mirabel, A. Curien and Li Chengda for administrative assistance. This is IPGP contribution no. NS 689.

Reversed critical wide angle reflection profiles of the crust–mantle boundary south of the Yarlung Zangbo suture in Tibet reveal a deep (70 km) Moho extending north from the High Himalayas, whilst to the south the Moho is 15 km higher. Even further south, reflections from 35 km depth may correspond to the Moho of peninsular India.

In September–October 1981 seven charges ranging from 2 to 10 tons were detonated in two lakes and at one drill-hole shotpoint between the High Himalayas and the Yarlung Zangbo Jiang as part of the French–Chinese geoscientific exploration of southern Tibet. Forty portable tape recording seismic stations were laid out to cover a 500-km long east–west line with a system of reversed and overlapping profiles, together with auxiliary profiles (Fig. 1). Twelve additional stations in Nepal tested the propagation through the High Himalayas. Details of the method, experiment and interpretation are presented elsewhere[1–3] and partly summarized below.

Interpretation of critical reflections

Critical reflections recorded from the crust–mantle boundary (Fig. 2*a*) are exceptionally clear when compared with former experiments on thick crusts of complex origin[4–9], a result partly attributable to propagation along the strike of geological units. The crust–mantle boundary can be modelled (using synthetic seismograms[10]) as a transition zone about 12 km thick at 75 km beneath the present-day surface (4,500 m mean elevation). Such a large crustal thickness was unexpected so near to the High Himalayas. In the upper crust strong variations in seismic response along the Tibetan line indicate significant structural variation, but reflectors at mid-crustal depth can be detected on most profile sections. Crustal mean velocity, derived from reversed observations of the Moho reflection, is of the order of 6.3 km s^{-1}, with upper and lower crust mean values around 6.0 and 6.4 km s^{-1}, respectively. The slope of the spectral ratio and the comparison of overall amplitudes of waves reflected respectively, on a mid-crustal interface and on the Moho provide a significantly high value for P-wave attenuation in the lower half of the crust of the order of 10^{-2}. Another peculiar feature

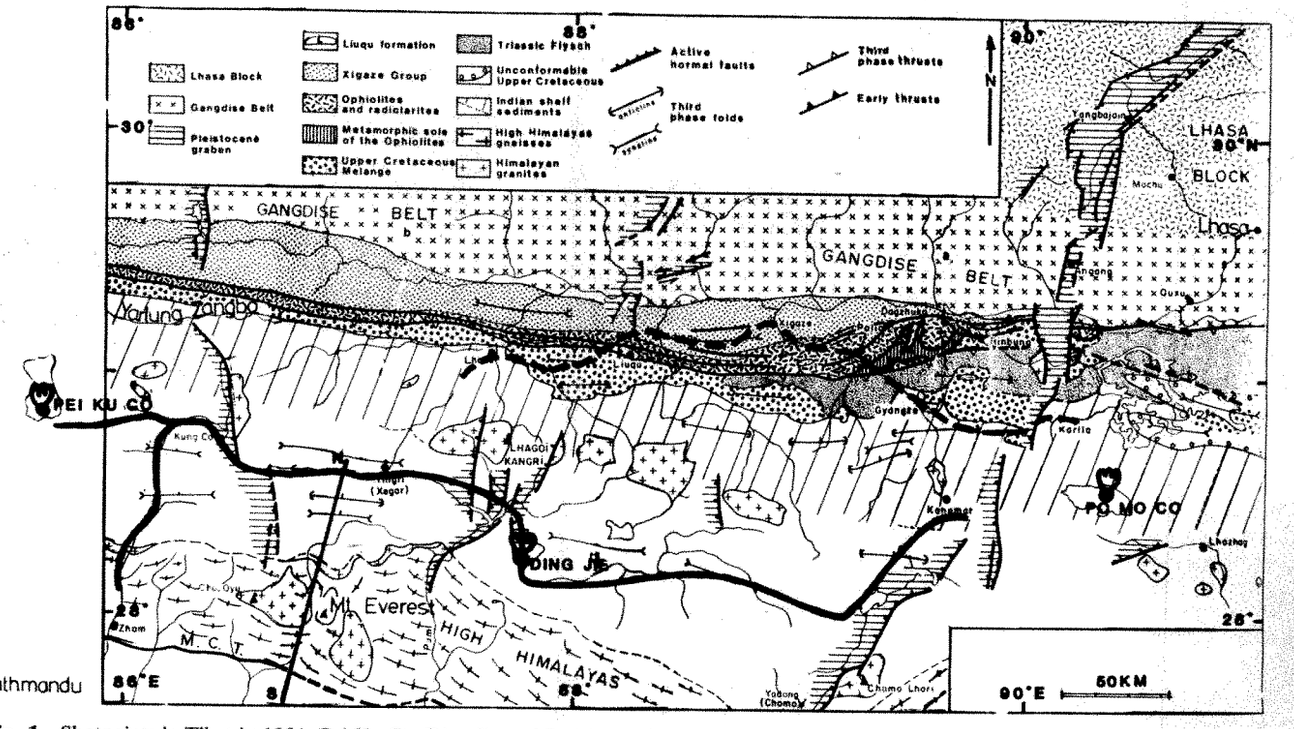

Fig. 1 Shotpoints in Tibet in 1981: Pei Ku Co, Ding Jie and Po Mo Co. Heavy lines are the location of profiles of seismographs with 10 km spacing. Geology is from Tapponnier *et al.*[18]. S–N is the position of the crustal section of Fig. 3.

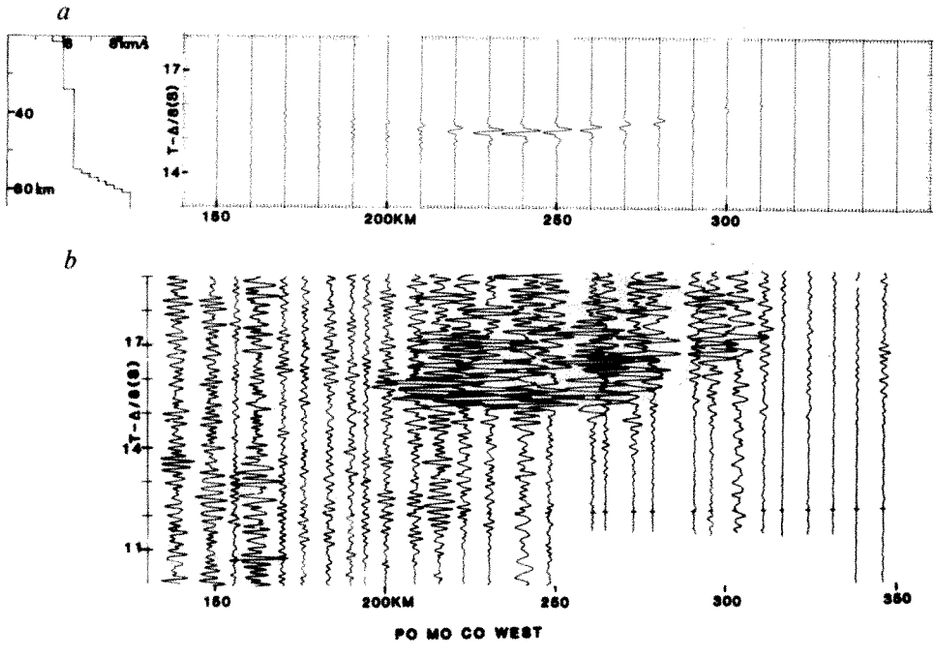

Fig. 2 *a*, Synthetic record section for a 12-km thick transition from crust to mantle velocity around 75 km beneath the surface. *b*, Shots Po Mo Co recorded on the east–west in-line profile. True amplitude record section reduced to 8 km s^{-1} velocity. Note the prominent burst of energy returned between 200 and 300 km distance and 15 and 16 s reduced time due to reflection at the Moho.

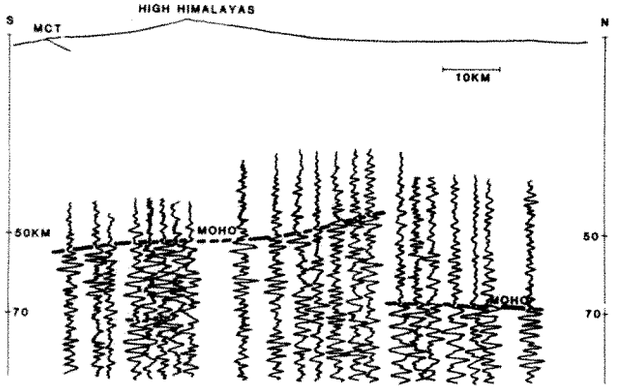

Fig. 3 Fan-profile to the west from shotpoint Dingjie. Correlated phases at these shotpoint distances from 180 to 300 km correspond to reflections at the crust–mantle boundary (see Fig. 2). Reflection times are corrected to a constant offset of 200 km, so that the time-section is directly transformed in a depth-section (S–N on Fig. 1) across the High Himalayas under the assumption of negligible variation of mean crustal velocity along it.

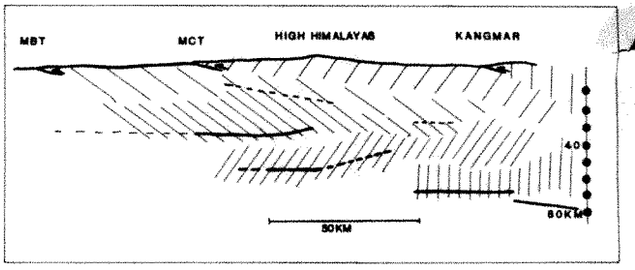

Fig. 4 Sketch of elements of seismic structure across the High Himalayas. Dashed line: interface between upper and lower crustal velocity material. Solid line: interface between crust and mantle velocity material. Loose hatching: upper crust layers. Their superposition is supposed to occur along flat thrusts at the base of the overriding unit. Tight hatching: lower lithospheric units. These are comprised of the lower crust, Moho and a sole of uppermost mantle material and are assumed to be brought to the present position, attested by the position and shape of the Moho marker, as a result of thrusting and superposition along levels of decoupling in the middle or lower crust and at shallow depth in the uppermost mantle. Possible correspondence of upper and lower units is indicated by hatching of same direction. MBT, Main Boundary Thrust; MCT, Main Central Thrust.

derived from the east–west reversed profile is a value of Pn velocity greater than 8.5 km s^{-1}.

North–south crustal profile

North–south crustal variation at the level of the Moho has been investigated using the relative arrival times of the reflections at critical-wide angle, that is, at 200–300 km range, on fan profiles in southern Tibet and across the High Himalayas to Nepal. Figure 3 shows a topographical cross-section of the deep crustal interfaces west of Mt Everest, obtained from a time-section of reflected waves at their mirror position. This section has been corrected for different offset distances and transformed into a depth-section assuming negligible variation of average crustal velocity. The deep Tibetan Moho is seen to extend to southwards to within a few tens of kilometres of Mt Everest. Another crust–mantle interface, probably dipping northwards, is seen at 55 km depth under the High Himalayas and partly on top of the Tibetan Moho. The mantle is deeper than expected beneath and south of the High Himalayas. Nevertheless, the depth to the mantle can be reconciled with the observed values of the gravity field[11,12] by taking into account the abnormal thickness of the low velocity upper half of the crust and the density deduced from the intermediate velocity value at the crust–mantle transition. However, the crustal section derived from explosion seismology no longer supports a continuous, smoothly north-dipping trend for lithosphere features beneath the Himalayan border of Tibet (a model which was suggested by gravity data and was consistent with a simple underplating of the crust causing a doubling of crustal thickness to the North[13]), nor slicing and superposing of crustal units on top of a decoupled, smoothly depressed Moho[14,15].

Evidence for further sharp topographical variations of the Moho to the north is derived from a fan profile between the High Himalayas and the Yarlung Zangbo. Here the crust–mantle transition zone appears to be composed of reflecting elements which may overlap each other at depth intervals of the order of 10 km (ref. 3).

To the south, and possibly on top of the Everest Moho (55 km depth), a reflector which could be another segment of crust–mantle interface is shown by a profile in Nepal through Kathmandu, in line with the western shotpoint in Tibet. Here the depth difference between these interfaces is of the order of

20 km so that the shallower one could be the Moho of peninsular India at 35 km depth[2].

Conclusions

Figure 4 summarizes the explosion seismology data by projection onto a cross-section from the Main Boundary Thrust (the southern extremity of the lower Himalayan domain) to the Yarlung Zangbo. This figure suggests that the observed thickening of the crust from north to south is not due to a smoothly north-dipping Moho. The amplitude of the steps is significantly smaller than normal crustal thickness, suggesting that the crustal doubling is not the result of the superposition of two whole normal crusts on each other, but rather the result of separate doubling (by decompling and thrusting) of the upper and lower crustal layers (plus Moho). The resulting structure would be consistent with the observation that the 70-km thick Tibetan crust can be divided into two layers of different mean velocities, each being twice as thick as the corresponding layers of normal crust.

The decoupling at mid-crustal depth thus implied may have occurred at the lower limit of the brittle layer or at the base of the upper, less basic layer in a compositionally layered crust[16]. Decoupling beneath the Moho might be related to the behaviour of a low velocity layer at a shallow depth in the mantle lithosphere[17].

The Sino–French geoscientific programme in Tibet has been promoted by the Foreign Ministries of both countries and discussed and supported by the French Institut National d'Astronomie et de Géophysique of CNRS and the Chinese Ministry of Geology and Academia Sinica. Additional effort in Nepal came from the Department of Mines and Geology. Contribution IPG 684.

Lhasa block and bordering sutures— a continuation of a 500-km Moho traverse through Tibet

Alfred Hirn*, Alexandre Nercessian*, Martine Sapin*, Georges Jobert*, Xu Zhong Xin†, Gao En Yuan†, Lu De Yuan‡ & Teng Ji Wen§

§ Institute of Geophysics, Academia Sinica, Beijing, China

A north–south wide-angle fan-profile through the Yarlung Zangbo suture, across the Lhasa block and through the Bangong-Nujiang suture shows several significant and sharp changes in crustal thickness. Both sutures appear as vertical 20-km steps in the Moho and may have been the loci for eastward strike-slip motion of the Tibetan lithosphere.

THE Yarlung Zangbo Jiang suture zone between southernmost Tibet, part of the Indian continental plate, and the Lhasa continental block, part of Asia since before the Cretaceous, was a major target for the seismic exploration of deep structure in the 1981–82 French–Chinese joint programme. The results of the first phase (an east–west profile in the south Tibetan zone between the High Himalayas and Yarlung Zangbo suture) are reported in the accompanying article[1] and elsewhere[2–4]. The second phase in June 1982 was intended to record a parallel line in the Lhasa block, to the north of this suture, to allow a comparison of structures. However, difficulty of access obliged us to displace it 300 km to the north, near the other limit of the Lhasa block. Consequently fan-recording was used to investigate crustal variation between these lines.

From a methodological viewpoint it is worth noting that the width of individual crustal segments between Moho disruptions thus defined is of the order of their thickness (50–100 km). As the critical distance for waves reaching the Moho is much larger (200 km) than this width, these segments could hardly have been resolved by waves propagating across them in a conventional north–south in-line shooting and recording except perhaps by using numerous tightly spaced shotpoints. Although, in principle, vertical seismic reflection profiling of the continental crust[5] offers the possibility of improved resolution of horizontal variations, significant attenuation in the deep Tibetan coast[3] would affect high frequency signals.

Depth-section

The depth section of deep crustal reflectors presented here can be tied in with sections further south discussed in the accompanying article[1] to establish a 500-km long Moho traverse north of Kathmandu (Fig. 2). Parts of it, principally in the northern third, are provisional, as the interpretation now in progress of east–west in-line profiles may add or modify some conclusions. The depth-section is obtained under the assumption that the average crustal velocity is regionally constant. Most seismograms were obtained at constant distance, 200–250 km, from shotpoints, so the plot is that of the time-section; in some parts, however, the data are corrected for larger offset distances. The largest uncertainty in the conversion of time into depth results from lack of control of possible variations in the sharpness of the velocity contrast across the Moho along the section. In contrast to vertical

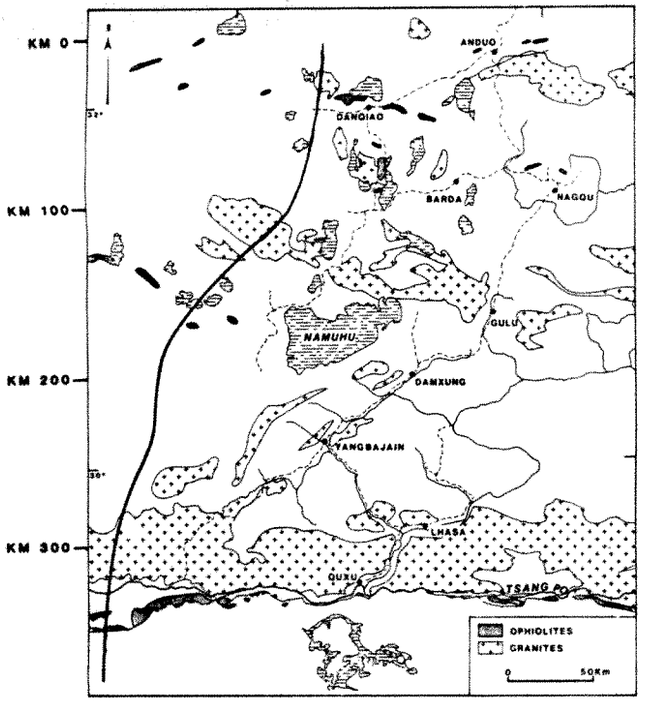

Fig. 1 Map with simplified geology, southern Tibet. The black line is the location of the seismic cross-section of Fig. 2. Data were recorded in a fan-like manner by seismic stations aligned along the main road through Quxu, Yangbajain, Gulu, Nagqu and Anduo at approximately equal distances of 250 km from two shotpoints to the west near latitudes 32° N at Shi Lin Co Lake and 29°5 N in drill-holes at Ang Ren. Distances (in km) from Fig. 2 are taken from the left side scale. South of km 300 the section of Fig. 2 is a composite of data discussed in the accompanying paper[1].

reflection profiling, only interfaces for which the offset of 250 km corresponds to the angle of incidence for critical reflection respond by sending back strong signals. Clear correlated onsets correspond to deep interfaces between crust and mantle material, and cannot originate as simple or multiple reflections from shallow levels or from deep levels with only small velocity contrasts.

North of the Himalayan region discussed previously[1], the 70-km deep Moho can be traced at approximately that depth until it is abruptly interrupted in the region of the Yarlung Zangbo. The Moho rises from a depth of 70 km only about 50 km to the north to a depth of 50 km below the river at km 330, where it is interrupted. What we detect here is a very sharp limit at the Moho level to the south of the Lhasa block. Lithospheric perturbation in this region of former oceanic subduction and suture seemed likely. However, the sharpness of the Moho depth variation was unexpected. We should stress that seismograms on both sides of it were obtained at strictly the same offset from the shotpoint just on the suture, so that there can be no ambiguity of data reduction. If the mantle wedge on the northern side is indicative of the direction of thrusting during subduction, the exact coincidence of the Moho step with the edge of the Gangdise granitic belt, a major structural and mechanical boundary, points to a vertical contact of crustal segments. This is a strong argument for considering this boundary as related to post-suture strike–slip motion. This heterogeneity in the lithosphere may represent one of the major shear zones for the eastward expulsion of lithospheric segments in the continuing motion of India towards Asia[6]. This motion could have preserved and enhanced the sharpness and verticality of the shear zone and taken advantage of the east–west linearity of the original suture.

Three hundred kilometres further north the Lhasa block is thought to be limited by an earlier suture, the Bangong-Nujiang line. The northernmost part of our section crosses a branch of the related ophiolite belt. There is a striking similarity between the northern 70 km of the Moho section and the topography beneath the Yarlung Zangbo suture. Here also we see a very sharp step of slightly less than 20 km in the depth of the Moho and the same polarity. The location of this step is coincident to within about 10 km with the geological boundary at the surface, so that the same aspect of probable verticality of contact between lithospheric segments is documented and the same considerations on post-suture strike–slip activity may hold.

Deep crustal features

For logistical reasons seismic recording stations were situated along the road through Lhasa, Yangbajing, Gulu and Nagqu, which is also a geologically well studied section. Because of the offset, however, seismic data sample the deep structure 100 km to the west, on the other side of the Niainqentangla range which interrupts the east–west structural trends. Thus, deep crustal features cannot be compared with geology in a simple way. In particular the extension to the west of the Damxung accident is not known and conversely the geological significance of the ophiolitic belt and of structural limits which are indicated on general maps and crossed by the seismic section, is not assessed. This central region appears to be the most complicated in the section. From km 330 to km 170 the average depth to the shallowest reflector of crust–mantle type apparently decreases from 70 to 50 km. However, at least four overlapping Moho segments can be identified, three of which are north-dipping, contrary to the general trend. From the Yarlung Zangbo, where it is at 50 km depth, the Moho dips to 70 km at km 300. At this point a further Moho segment is seen on top of it, dipping northwards from 55 km depth at km 300 to more than 75 km at km 230.

Near km 260, data to the south are from the Ang Ren shotpoint whereas to the north they are from Shi Lin Co. When approaching from the south the Moho dips from 60 to 70 km over 30 km distance. When approaching from the north the shallowest reflector is at 50 km, also dipping north. The energy, at this offset, of strong late arrivals suggests these can be attributed to a deeper crust–mantle velocity contrast. The depth and dip of this second level allow it to be tied in continuously through km 260 with the Moho defined from the other side and from another shotpoint. The geometry of these reflector segments could be described as the southward over-thrusting of three north-dipping lower crust layers on each other.

From km 230 to km 170 the depth to the Moho decreases from 50 to 40 km, although with local changes in dip. The succession of overlapping north-dipping reflectors followed in the south of the Lhasa block is interrupted by a new step when the shallowest level, 45 km, is reached at km 160. Contrary to findings in the south, one interpretation here is the northward overthrusting of a south-dipping deep crust segment. Alternatively, as second arrivals after those of the shallow reflector are not followed far to the south, a vertical step in the Moho without overlapping can be postulated.

In the region to the north (from km 120 to km 70), throughout the Bangge–Gulu granitic belt, the base of the crust is apparently about 50 km deep, the shallowest in the whole section. This zone is however tectonically very complicated, with further large ophiolite bodies. Variations in structure are also deduced from an additional east–west seismic profile perpendicular to the section presented here which may thus not be completely representative; furthermore, reflections deeper than this shallow Moho may be present. That such structure exists deeper can also be supposed from the significant signal level in later parts of the seismograms; it is likely that further crustal material is present beneath the shallowest mantle material at 50 km depth.

Tectonic interpretation

The considerable departure of the crust–mantle boundary from the horizontal along the section suggests that crustal thickening did not occur through mere underplating of several hundred kilometres of continuous Indian crust beneath Tibet, unless the

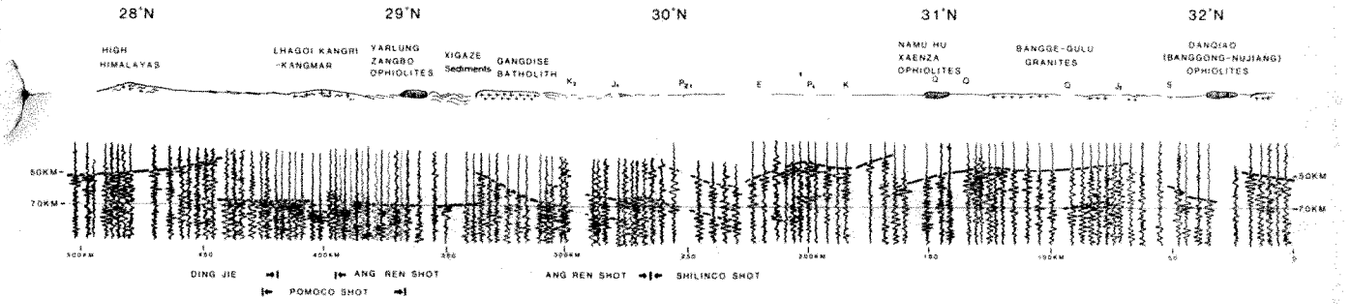

Fig. 2 Time-section of Moho reflections at constant offset of 250 km, that is, critical to the wide angle. This is a depth-section of the topography of the crust–mantle boundary along the line of Fig. 1 assuming negligible variation in average crustal velocity along the section. Approximate distances are counted along the north–south projection. Note the 20 km change in Moho depth across sutures (km 330, Yarlung Zangbo; km 30, Bangong-Nujiang; possibly km 160, Namu Hu ophiolites) thought to indicate later strike–slip motion on vertical block limits. Note also, for example, between km 180 and km 350, successive dipping and overlapping segments of crust–mantle reflectors indicating thickening of deep crustal levels as a result of the superposition of neighbouring pieces of lower crust along deep thrusts.

deep crust topography is due to more recent disruptions. We attribute the occurrence of vertical steps in the Moho, coinciding with major surface lineaments vertically above them (as documented for the two former suture zones bordering the Lhasa block), to such phenomena, mainly to horizontal strike–slip on major east–west lithospheric fractures due to the expulsion of Tibet to the east. The Moho step at km 160 could be interpreted in the same way unless the nearby ophiolite belt (west of Namu Hu) is an allochthonous unit or if prominent strike–slip features can be identified at the surface, as in the case of the Damxung accident on the other side of the Niainqentangla. The overlapping of dipping segments of the Moho noted at several places would suggest intracontinental thrusting of neighbouring crustal slices onto each other as a means of thickening the crust. No data on a possible subdivision of the thick crust of the Lhasa block are available as they were for the southern block towards the Himalayas.[1] It is worth noting however, that, as was the case there, the thickness of crustal units which are seen to interact at depth is less than 20 km. A similar picture of thickening of the lower crust by superposition of neighbouring lower crust units may thus be obtained. The complete thickening of the crust would then also have needed superposition of neighbouring segments of upper crust layers along major thrusts. They could have the same polarity as the lower crust thrusts or the opposite one, as seems to be the case at the Himalayan border. As the part of the Lhasa block north of the Gangdise belt and west of Niainqentangla is not easy to reach, no geological study documenting surface expression of crustal thrusts is available with which to consider this hypothesis.

The Sino-French geoscientific programme in Tibet has been promoted by the foreign ministries of both countries and discussed and supported by the French Institut National d'Astronomie et de Géophysique of CNRS and the Chinese Ministry of Geology and Academia Sinica. Contribution IPG 685.

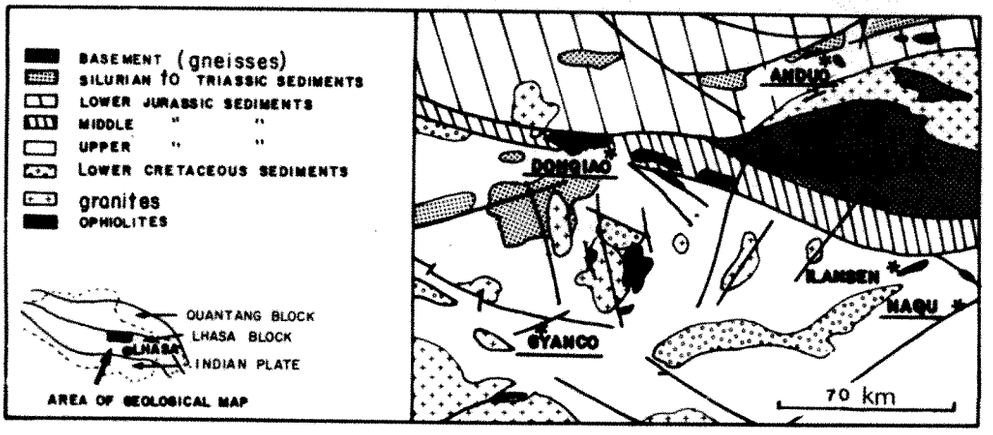
The Bangong-Nujiang suture zone is underlain by a discontinuous and roughly EW ophiolite belt. Around Donqiao–Gyanco, ophiolitic and metasedimentary Palaeozoic series form nappes thrusted over Jurassic flysch series. All these series have undergone a late symmetrical folding accompanied by generally northward reverse faulting. Although strongly dismembered, a complete ophiolitic sequence comprising harzburgites with large podiform-type chromite deposits, wehrlites, cumulate gabbros, sheeted dolerite dykes, foliated garnet-bearing amphibolites and pillow lavas, has been found.

THE Tibetan plateau, which probably results from successive accretion of several continental blocks to the south of Eurasia, is cross-cut by two major EW suture zones[1,2]. To the south, the Yarlung Zangbo suture zone is underlain by a nearly continuous ophiolite belt over several hundred kilometres. The latter separates the Indian plate to the south from the Lhasa block to the north. In the Xigaze area, the ophiolites form a slice a few kilometres thick thrusted to the south onto the Himalayan series. Although strongly dismembered, it shows a continuous ophiolite sequence, whose most peculiar feature is the occurrence of dolerite sills and dykes throughout the whole sequence from the basal fresh peridotites up to the Upper Albian–Lower



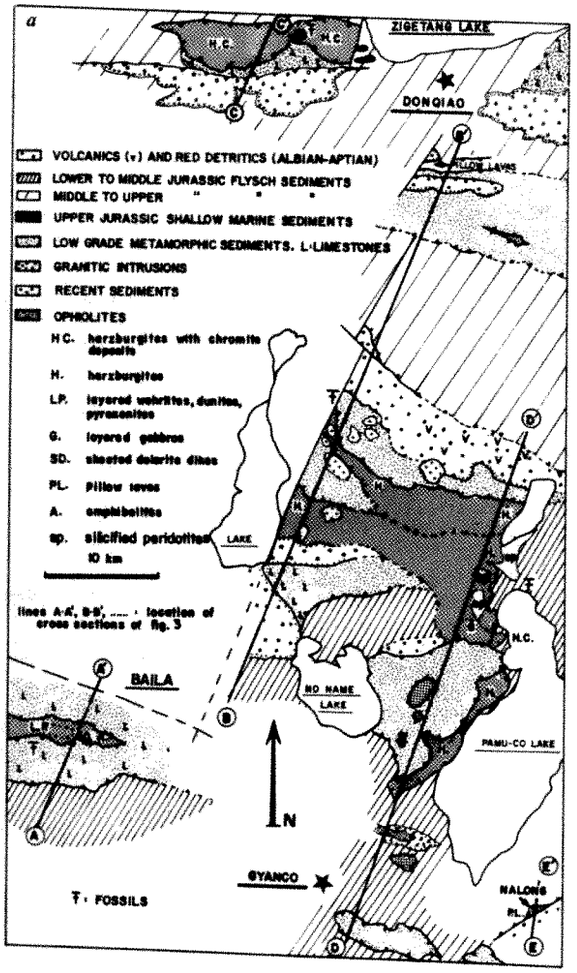


Fig. 1 The Bangong-Nujiang suture zone in the Anduo–Donqiao–Gyanco-Gulu area (from the Chinese 1/1,500,000 scale geological map).

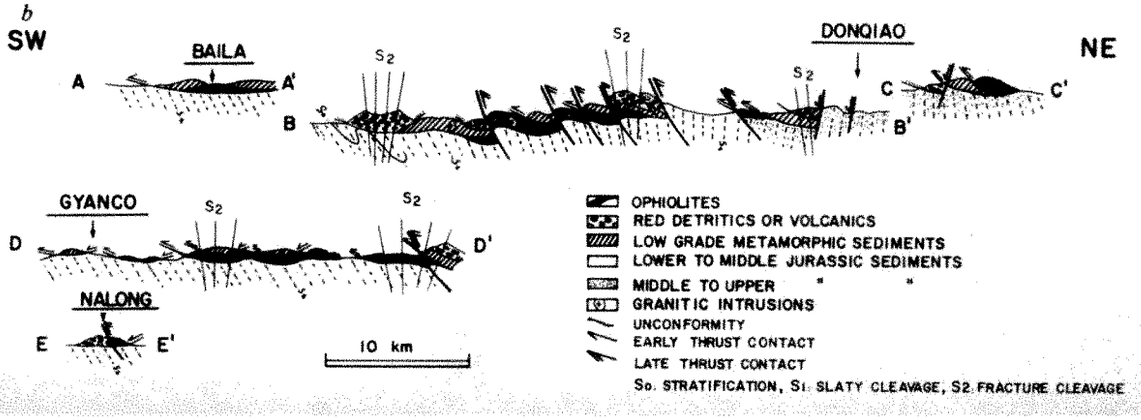
Cenomanian pillow lavas[3–5]. The ophiolite was probably obducted during the Eocene[6,7].

The Bangong-Nujiang suture zone[8–11] separates the Lhasa block to the south from the Quantang block to the north (Fig. 1). It is located approximately 300 km north of the Yarlung Zangbo suture zone and forms poorly defined EW belt several hundred kilometres long running from the north of Laddack to the west, to Nujiang valley (Salouen River) to the east, and is locally underlain by ophiolitic massifs. Very few data have been published on the tectonics of this suture zone[8–11].



The observations presented here were obtained in the Donqiao–Gyanco area, during the 1981 field work of the 3-yr French–Chinese joint project in Tibet. This area has been mapped at a scale 1:100,000 over a distance of nearly 100 km from north to south between Donqiao and Gyanco, with an approximate EW width of 30 km.

A synthetic cross-section in that area shows, from bottom to top, a succession of Jurassic flysch, and ophiolitic and Palaeozoic metasedimentary series. They all stand in flat tectonic contact with each other and are overlayed in angular unconformity by Aptian–Albian red detritics and volcanics. The lithological and structural characteristics of the different series and their geodynamic significance are discussed.

Lithological and structural characteristics

The most representative outcrops of the Jurassic flysch series can be observed along the eastern side of the Pamu-Co Lake and immediately north of No-Name Lake (Fig. 2*a*). This series consists of rhythmic intercalations of dark shales, slates and yellow sandstones with scarce bio-detritic limestones forming lenses several metres thick. Fossils indicate a Middle Jurassic age (Aalenian) in the Gyanco area (*Gutnicella* (*Lucasella*) *cayeuxi*, *Haurania* sp. and *Nauticulina* sp. in sample XSM 96)

Fig. 2 *a*, Lithological and structural map of the Donqiao–Gyanco area. *b*, NNE–SSW sections through the Donqiao-Gyanco area (location of sections on *a*; topography has not been respected).

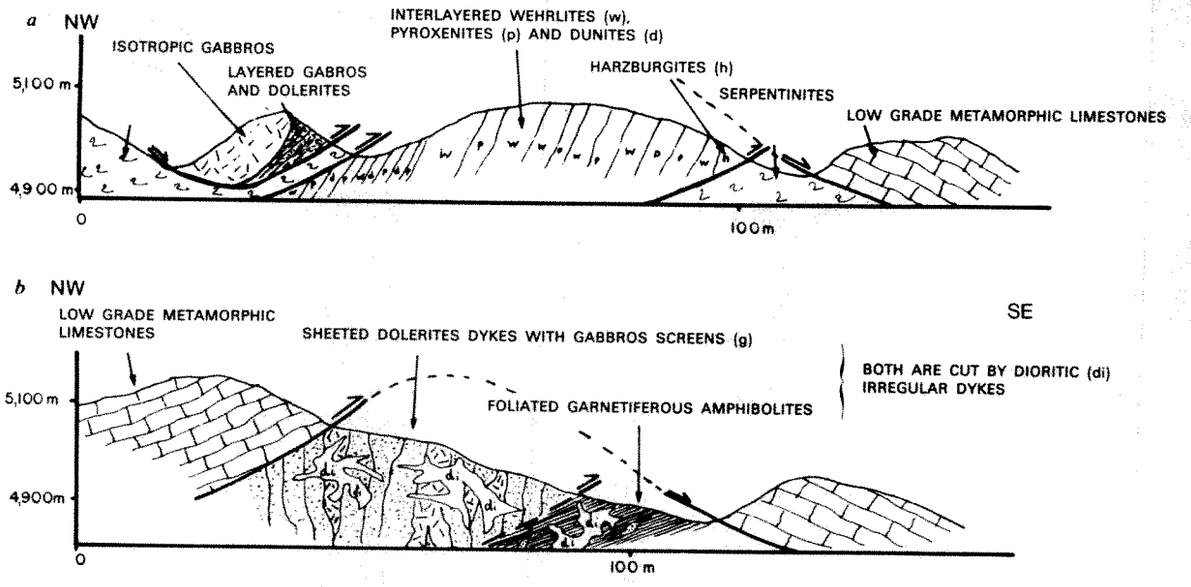


Fig. 3 NW-SE sections through the Baila massif. *a*, Wehrlites and gabbros section; *b*, sheeted dolerites and foliated amphibolite section.

and a Malm age around Donqiao (gastropods, *Sequania* sp.; G. Termier, personal communication).

This sedimentary series has undergone a low-grade metamorphism (sericite–chlorite) and shows N 060 trending asymmetrical folds with subhorizontal axes and a generally north-dipping slaty cleavage S1 (~60°) parallel to their axial planes. In the Donqiao area, this cleavage is vertical or south-dipping (Fig. 2*b*). The F1 folds north of No-Name Lake seem to be overturned to the south. A subvertical late crenulation cleavage S2, related to large symmetrical folds, is locally superimposed on the previous structures.

The ophiolite series tectonically overlies the Jurassic sedimentary series everywhere, their basal contact being marked by low-temperature tectonic breccia, silicified peridotites or schistose serpentinites. Although the ophiolite sequence has been strongly dismembered and scattered, all the different parts of a typical ophiolite suite are found in the Donqiao–Gyanco area. They are:

(1) Residual harzburgites. These largely outcrop in the Donqiao massif and in minor amounts on the western side of Pamu-Co Lake, and in the Baila and Nalong massifs (Fig. 2*a*). Some serpentinites are also observed in the Ilansen area (Fig. 1) and about 20 km east of Amdo (Fig. 1). The harzburgites generally show porphyroclastic structures typical of low-stress high-temperature deformations[12,13]. They are, however, serpentinized and locally schistosed in shear zones related to EW subvertical late northward reverse faults. In some places the harzburgites are rich in dunite patches several metres in size and bear many podiform-type chromite deposits. These deposits, which are surrounded by irregular dunite walls, can reach several tens of metres in size and stand at a steep angle (40°) to the primary foliation plane. The chromite is massive with only a few local interstitial olivines transformed into serpentine. The foliation plane and lineation measured in the harzburgites show nearly constant orientations of about N 060, NW 70 and N 055, NE 17, respectively.

(2) Wehrlites, clinopyroxenites and dunites. These occur only in the Baila massif (Fig. 2*a*), approximately 30 km WNW of Gyanco where they outcrop as a window beneath Palaeozoic metasedimentary rocks (Fig. 2*a*). From south to north a section through this massif (Fig. 3*a*) shows (upwards) a few metres of harzburgites overlain by ~50 m of alternating bands (up to 5 m thick) of wehrlites and clinopyroxenites and ~30 m of more layered rocks composed of 10–30-cm thick layers of dunites, clinopyroxenites and wehrlites.

(3) Troctolites, layered and isotropic gabbros. These have been

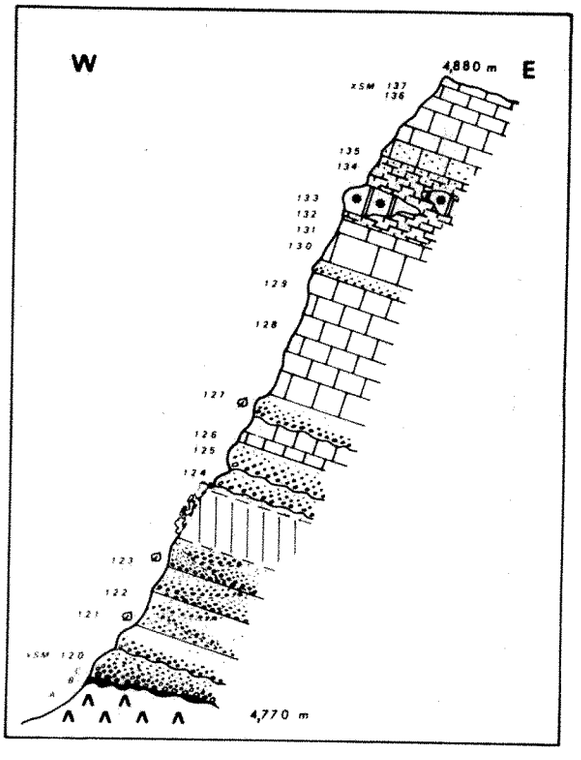

Fig. 4 The transgressive Zigetang formation. From bottom to top: A, serpentinized harzburgites and dunites; B, red silicified encrustings; C, coarse-grained conglomerate with chromite pebbles. Sandstone member, XSM 120 to 127, thick-bedded terrigenous sandstones (cross-bedded laminations and plant remains); calcareous member, XSM 128 to 137, mainly well bedded calcareous mudstones, wackstones, subordonate terrigene influx and patchreefs (XSM 133). Depositional environment: sub-aerial deltaic for XSM 120 to 127 to very shallow marine for XSM 128 to 137. Biostratigraphic content: XSM 122, grainstones with coral remains, *Cladocoropsis* sp. *Pseudochaetetes* sp., algae (Salemoporaceae), *Pycnoporidium lobatum* Y. and T. Foraminifers: *Kurnubia* sp. (or *off. Kurnubia*), *Pseudocyclammina* sp., *Nautiloculina* sp., XSM 133, boundstone with *Cladocoropsis* sp. and Stromatoporidae; XSM 137, mudstone, wackstone with Dasycladacae, *Salpingaporella annulata* Carozzi, *Trinocladus perplexus* Elliot.

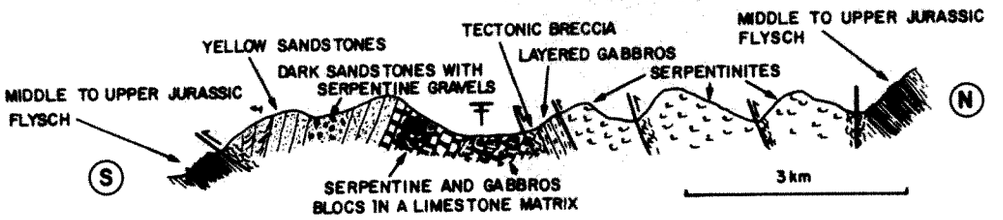

Fig. 5 NS synthetic section across the Ilansen olistostrome formation.

found on the western side of Pamu-Co Lake and in the Baila massif (Fig. 2*a*). Their total thickness does not exceed 50 m. In the Pamu-Co Lake area, troctolites form lenses several metres long and 5–10 m wide which are intercalated with olivine gabbros. They are overlain by a few tens of metres of slightly-layered plagioclase-rich gabbros. In the Baila massif, mafic rocks form a slice in tectonic contact over serpentinized harzburgites and over the previously described wehrlites, clinopyroxenites and dunites (Fig. 3*a*). It consists of approximately 10 m of interlayered fine-grained gabbros and dolerites overlain by 20–30 m of mainly brown amphibole-rich isotropic gabbros and dolerites in minor amounts.

(4) Sheeted dolerites and foliated garnet-bearing amphibolites. Approximately 50 m of sheeted dolerites overlie foliated garnet-bearing amphibolites a few tens of metres thick in the Baila massif area (Fig. 3*b*). The 1-m thick dolerite dykes are intrusive either in scarce isotropic gabbros or in older intrusive dolerite dykes. They generally show two chilled margins. The sheeted dolerites tectonically overlie foliated amphibolites. Both the sheeted dolerites and the foliated amphibolites are intruded by diffuse and interdigitated amphibole-bearing leukocratic diorite. This late undeformed intrusive shows chilled margins with surrounding rocks.

(5) Lava flows and pillow lavas. These outcrop in the Nalong massif, ~20 km east of Gyanco (Fig. 2*a*), and also in the Anduo village (Fig. 1). In the Nalong massif, the volcanics form several tectonic slices limited by late reverse north-dipping faults, and are thrusted to the south over the Aptian–Albian red continental series[14]. The volcanics, which are ~100 m thick, at their base (that is, to the south) comprise mainly massive lava flows several metres thick and, at the top, are formed of pillow lavas with a few hyaloclastite levels. The pillows (40–70 cm diameter in section) are generally variolitic. They display a general northward normal polarity. Lava flows and pillow lavas are cut by rare diabase dykes.

The allochthonous low-grade metamorphic sedimentary series is mostly composed of grey limestones, and of minor yellow-banded quartzites below dark shales. This series is observed in many places in the Donqiao–Gyanco area (Fig. 2*a*). This sedimentary series generally lies over the Jurassic flysch or the ophiolite series but can be locally overthrusted by the ophiolite series, as in the Donqiao area (Fig. 2). We have found no specific

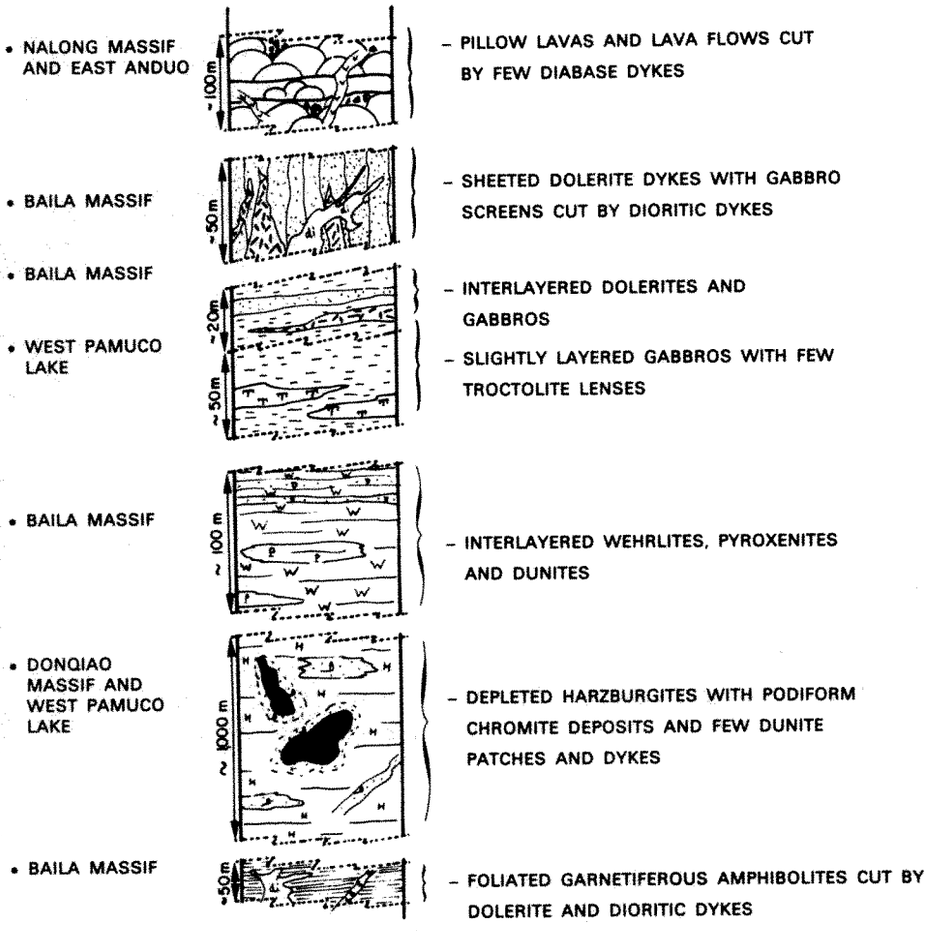

Fig. 6 Restored synthetic section through the Donqiao ophiolitic sequence.

fossils in this low-grade metamorphic formation, which is considered to be Upper Palaeozoic (C. F. Chang, personal communication). This series locally shows south-facing folds. It has been intruded by granites forming locally dykes oriented at about N 120, N 30.

Red detritics comprising conglomerates, red sandstones and shales largely outcrop in the Anduo–Donqiao–Gyanco–Gulu area (Fig. 1). Volcanics occur only north of Pamu-Co Lake where 5-m thick basaltic flows intercalated with thinner vesicular andesitic flows and a few ignimbritic flows lie unconformably above serpentinized peridotites (Fig. 2*a*). These volcanic series, some 10 m thick, are also covered in angular unconformity by red detritics beginning with coarse conglomeratic beds rich in pebbles of volcanics. Upwards, some thin pelite beds and rare ignimbrite flows a few centimetres thick are intercalated within the coarse conglomerate banks. These series, which are ~100 m thick, seem to be covered to the north by a thick yellow volcanic pile.

Biostratigraphical datations have given an Aptian–Albian age for the red sandstones and pelites which outcrop east of Gyanco[14]. The volcanics or red detritics overlie in unconformity the Jurassic flysch series as well as the ophiolitic or Palaeozoic metasedimentary series described above. The volcanics and red detritics are not metamorphic but, in addition to the underlying series, have undergone a symmetrical folding with N 140 axes, accompanied by a fan-shaped spaced cleavage.

North of Donqiao, the chromite-bearing peridotites (Fig. 2*a*) are covered by a transgressive detritic shallow marine formation called the Zigetang formation[15]. It begins with coarse-grained conglomeratic levels containing chromite pebbles transgressing red silicified peridotites (Fig. 4). At the top the conglomerate beds are interbedded with thick terrigenous sandstone beds. This sub-aerial deltaic 40-m thick unit is covered by very shallow marine sediments mainly comprising well bedded calcareous mudstones, wackstones. subordinate terrigene influx and some patchreefs. The thickness of this strongly eroded formation does not exceed 130 m. The numerous foraminifers and algae we have found (see Fig. 4 legend) indicate an uppermost Jurassic–lowermost Cretaceous age.

In the Ilansen area (Fig. 1) the ophiolitic series constitute an olistostrome formation southward thrusted over an Upper Jurassic flysch series. From north to south a section across this massif (Fig. 5) shows (downwards) the stratigraphical succession of yellow sandstones displaying abundant cross-bedded figures indicating a normal polarity to the south, serpentine-bearing sandstones and grey limestones locally rich in angular layered gabbro blocks of various sizes. The contact-between the limestones and the peridotites to the south has not been observed. The grey limestones in which the gabbro blocks are cemented are rich in corals and gastropods, indicating a probable Upper Jurassic age.

The Donqiao ophiolite

A typical ophiolitic sequence, though strongly reduced in thickness (the cumulated thickness is 1,400 m), has been found in the Donqiao–Gyanco area (Fig. 6). This ophiolite is very similar to those previously described elsewhere[16]. It is composed of a mantle part comprising harzburgites which clearly represent residual rocks, wehrlites, pyroxenites and dunites which can be either cumulates or impregnation rocks, and of a crustal part composed of cumulate-layered gabbros, sheeted dolerites and volcanics. The foliated garnet-bearing amphibolites, which lie beneath the sheeted dolerites, could represent remnants of a metamorphic sole, as is seen beneath many ophiolites[17]. The occurrence of large podiform-type chromite deposits is the only peculiarity of this ophiolite sequence. The first geochemical data analysis performed on this ophiolite indicates that it could have been formed in a small ocean in a subduction zone environment and is distinct from the Kigaze ophiolite to the south[18].

Tectonics and geodynamics

Several successive tectonic events can be defined in the different units:

(1) The first tectonic event, D1, has led to folding of the Jurassic flysch series in which south-facing folds accompanied by axial-plane slaty cleavage can be locally observed. This tectonic event has been followed by a large thrusting tectonic event D1-2 corresponding to the southward emplacement of the ophiolites and of the Palaeozoic metasedimentary rocks onto the Jurassic flysch series. Thrusting was from north to south as demonstrated by the NS direction of stretching lineations in limestones beneath the ophiolite series and by subsequent shear structures.

(2) A second folding event, D2, inducing the formation of large symmetrical folds accompanied by vertical fracture cleavage postdates the deposition of the Aptian–Albian red detritics and associated volcanics and deforms all the basal sedimentary or thrust contact planes. It is followed by large reverse faultings producing thrusting of the Upper Jurassic flysch and of the ophiolites over the Lower Jurassic flysch and red detritics, respectively.

The obduction of the Donqiao–Gyanco ophiolite occurred at the Upper Jurassic, as the ophiolite is trangressively covered by uppermost Jurassic–lowermost Cretaceous sub-aerial to shallow marine sediments.

It is therefore likely that the D1 tectonic event observed in the Middle to Upper Jurassic flysch series is due to the obduction of the ophiolite. The obduction probably occurs from north to south as indicated by both the vergence of folds in Jurassic flysch series and the stretching direction and sense determined at the base of the nappes. This obduction can be related to a north-dipping subduction zone which should have been located northwards and could have resulted from the uppermost Jurassic–Lower Cretaceous collision between the Lhasa and the Quantang blocks.

The D2 folding and associated reverse faulting events occurred in the same time span as the folding of the Takena formation to the south (upper part of the Lower Cretaceous) which is probably related to the Eocene India–Eurasia collision[2,6,7].

The Donqiao ophiolite yields new information on the Bangong-Nujiang suture zone. A quite similar suture zone has been described west of Tibet in the Farah Rud, Afghanistan[19,20] and to the east in the Sittang Valley Mytkyina zone in Burma[21,22], where the obduction of the ophiolitic series occurred at the same time (Upper Jurassic to lowermost Cretaceous) during a wide Neo-Cimmerian tectonic crisis along the South Eurasian margin.

We thank J. C. C. Mercier and J. P. Burg for their critical review of the manuscript, G. Termier for fossil determinations and R. Guez for technical assistance. This work has been supported by INAG, through the French–Chinese Three Year Cooperation Project in Tibet. IPG contribution no. 690.

High heat flow in southern Tibet

Jean Francheteau*, Claude Jaupart*, Shen Xian Jie†, Kang Wen-Hua‡, Lee De-Lu‡, Bai Jia-Chi‡, Wei Hung-Pin‡ & Deng Hsia-Yeu§

* Institut de Physique du Globe, Université Paris 6, 4 place Jussieu, 75230 Paris Cedex 05, France

§ Institute of Geophysics, Academia Sinica, Beijing, China

Heat flow measurements have been attempted in two freshwater lakes at altitudes of 4.5 and 5.0 km, south of the Yarlung–Zangbo suture zone in southern Tibet. Probe penetration in the lake sediments was deep enough in the case of eight measurements (5.5–7.2 m) to give reliable temperature gradients. Corrections for seasonal temperature variations, topographic and refraction effects have been applied to the data. In a north–south profile trending perpendicular to the Yarlung–Zangbo suture zone, heat flow is approximately constant at 146 mW m^{-2} over a distance of 30 km and drops to a value of 91 mW m^{-2} in <25 km. The high heat flow and the sharp spatial variation both suggest the existence of a heat anomaly located at relatively shallow depths (no greater than 25 km) in the Tibetan crust, probably due to the recent emplacement of plutonic bodies.

TIBET is a massive plateau with a vast areal extent (2.5×10^6 km^2) at an unusually high elevation (5 km above sea level). It holds a privileged geodynamic position north of the India–Asia collision zone between the Himalaya and Kun Lun mountain ranges. The origin of this remarkable broad regional uplift is still unresolved. Somehow, it must be related to the overly thick (70-km) crust determined by different seismic studies[1,22]. Any model for the plateau uplift must use as a constraint the thermal regime at depth. So far, educated guesses have only been made about a representative geotherm when trying to model the tectonics of Tibet[2] or when trying to recover the uplift rate from fission track analyses in Himalayan rocks[3]. The Tibetan plateau is characterized by strong geothermal activity with numerous boiling springs, hot springs and even geysers scattered over most of its area[4]. Because the rheology of rocks depends strongly on temperature, the thermal structure of Tibet is a most important parameter for understanding the processes active in a continent–continent collision zone. Some predictions have been made. Wang and others[2] assumed a heat flow value of 84 mW m^{-2} on the basis of poorly constrained correlations between heat flow and age in geological provinces[5]. The existence of a thick crust enriched in radioactive elements would also yield a high heat flow. The lack of conductive heat flow measurements leaves the question unsettled. During the last field programme of the French–Chinese cooperation for the study of Tibet and the northern Himalayas which was started in 1980, it was decided to carry out heat flow measurements using oceanographic techniques in the numerous lakes which dot Tibet. The measurements reported here are the first known conductive heat flow measurements in Tibet.

Measurements

Many heat flow measurements have been made in lakes using the oceanic probe technique[6]. They have the obvious advantage that the cost and time required are much less than those needed for boreholes, tunnels or mines. Unfortunately, they are associated with many difficulties. For example, the recent and fast erosion of a lake depression leads to an artificial increase of temperature gradients[7]. These difficulties have been encountered in the Alps where deep lake heat flow data appear systematically higher than tunnel or borehole data[7,8]. There are fewer problems in small and shallow lakes which have been shown to yield results comparable to those from deep boreholes[9]. The ideal lake is probably not too deep, so that the transient erosion effects mentioned above are small, and not too shallow, so that thermal conditions in the lake are rather stable. In Tibet, our main problem has been to find such lakes as well as a suitable vessel from which to conduct the measurements.

We used a pontoon, which could be assembled and disassembled in a few hours, 10×12 m, about 1 m high on the water and powered by three outboard motors. A derrick had been erected in the middle and a gasoline-powered winch permitted the instruments to be lowered on a standard steel cable.

We used seven equally spaced (60 cm) thermistors mounted on outriggers tied either to the 4.5-m long barrel of a standard Kullenberg piston corer or to a thin (48-mm diameter) 6-m long metal rod used in quarry drilling operations. Both the corer barrel or the metal rod were clamped to a Kullenberg coring head with ~250 kg weight. A trigger weight enabled the barrel

Table 1 Heat flow data

The average heat flow for Yang-Zho-Yung lake (stations 6, 10, 14–16) = 146 ± 17 mW m^{-2} (excluding station 15). Average heat flow for Pu-Mu-Yung lake (stations 17–21) = 91 ± 5 mW m^{-2}. G_1 is the uncorrected temperature gradient which can be estimated from the deepest data points. G_2 is the temperature gradient after correcting for seasonal bottom-lake temperature fluctuations. T_1 is the average bottom-lake temperature, obtained after extrapolating the corrected temperatures.

or rod to free fall through the last 2 m of the water column before penetrating the sediments.

The temperature recorder for the seven sediments and one water temperatures was housed in a basket fastened to the coring head. We used an AANDERAA recorder modified for oceanic heat flow work at the Centre Océanologique de Bretagne, France. Temperatures were recorded internally on magnetic tape which could be read later in our base camp Lang-Ka-Zhe (Fig. 1).

Water depth was monitored by a Furuno FE-400C echo-sounder operating at 50 kHz and good to 480 m. We lacked a 3.5-kHz seismic system so that the sediment thickness was assumed from previous drilling by a Chinese party in one of the lakes (Yang-Zho-Yung lake). Navigation was by means of triangulation on key-features of the shore using large-scale topographic maps (1:100,000) and a hydrographic circle good to 1°.

Conductivity measurements were made on cores using the standard needle-probe method[11].

The two lakes where heat flow work was feasible during our field trip are located south of the Yarlung-Zangbo suture zone (Fig. 1). The northern lake, Yang-Zho-Yung, lies 4,400 m south of a prominent range. It is very tortuous in plan view (Fig. 1) and clearly represents a blocked river valley which used to drain into the Zangbo river and which probably got cut off through tilting in the active extensional tectonic zone striking roughly north–south between Yadong and Gulu[12] (Fig. 1). On the basis of a preliminary description of one core from the deepest part of the lake (core K1), the sediments consist mainly of light-grey, carbonate-rich muds including many layers with grassy mats and seem to have sedimented quietly (K. Kelts, personal communication).

The southern lake, Pu-Mu-Yung, lies at 5,000 m altitude just to the north of the Himalayan mountain range (Fig. 1). Some glaciers feed into the lake. One core (core K4) shows that the sediments are siltier with less admixture of carbonate and fewer diatoms. The core material is being studied for mineralogy, ^{14}C dating, palynology, organic content and ^{210}Pb.

The temperature measurements were conducted by selecting a site away from the shore, lowering the probe 10 or 5 m off the bottom for a few minutes, free-falling the probe into the sediments and waiting for 17 and up to 70 min in the sediments. The thermistors were off scale in the bottom water so that possible instrumental bias between the probes could not be removed.

Results

Four cores about 5 m long were taken before or during the temperature measurements. To check on possible conductivity changes between stations, outrigger sampling was undertaken at 12 stations. A total of 124 conductivity measurements including 24 repeated runs were made within 12 h after samples were retrieved from the lake bottoms.

The results show that thermal conductivity is rather uniform both horizontally and vertically (Fig. 2). There is good agreement between measurements on core and outrigger samples, although a subtle tendency can be detected showing a slight underestimation of conductivity in the outrigger samples, which can be attributed to a slightly different water content. There is no systematic variation of thermal conductivity with depth, except for the lowermost part of the cores (40 cm) where a dramatic increase of k values occurs, presumably due to compaction at the end of penetration (Fig. 2). These high values were omitted from the data set. We therefore used simple average values of 2.00 ± 0.16 (8%) and 2.09 ± 0.20 (9%), in units of 10^{-3} cal cm^{-1} s^{-1} °C^{-1}, for Yang-Zho-Yung and Pu-Mu-Yung lakes respectively.

According to the diffusivity–conductivity relation reported by Von Herzen and Maxwell[11], the thermal diffusivity of these sediments should be $\sim 2.5 \times 10^{-3}$ cm^2 s^{-1}. This value will be used throughout this study.

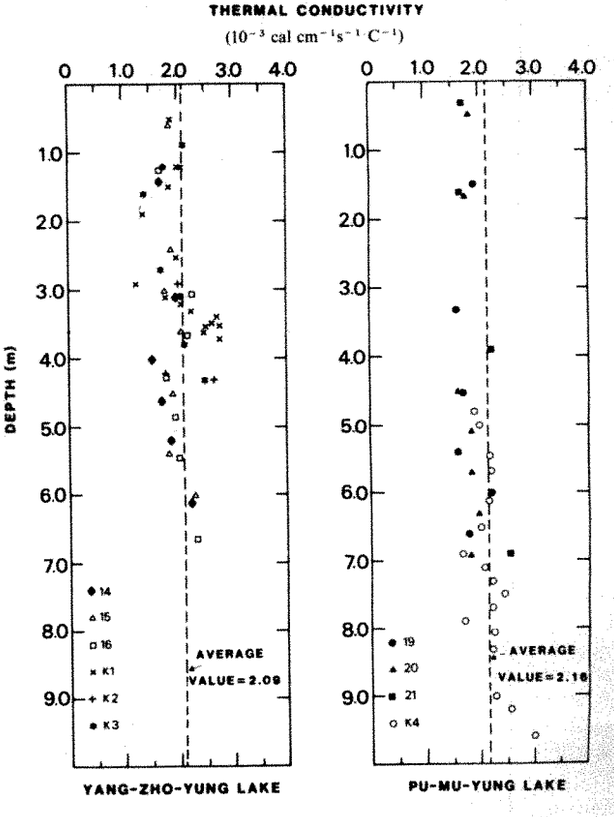

Fig. 2 Thermal conductivity of sediments from the two Tibetan lakes. The average value is that for all measurements.

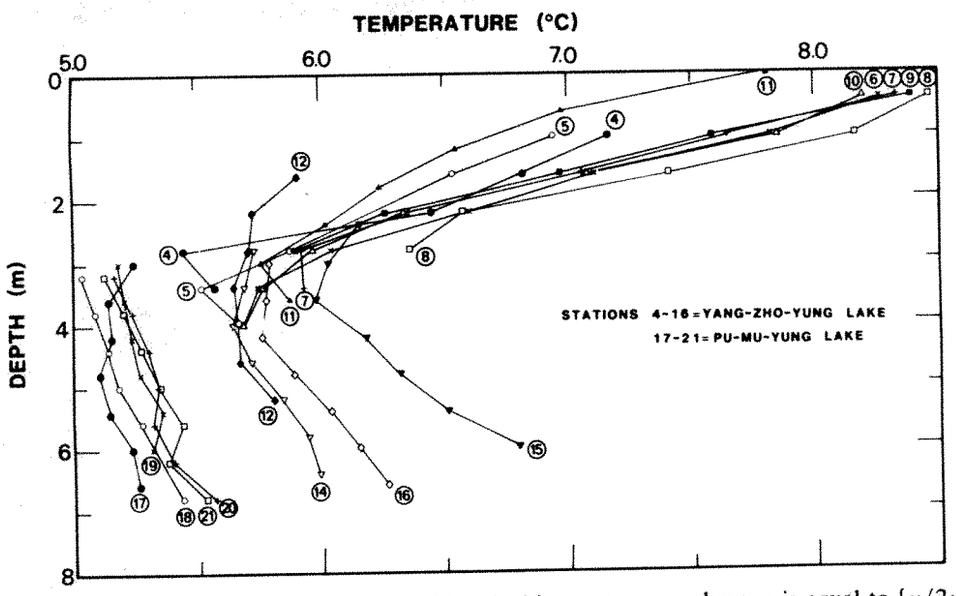

Fig. 3 Temperature versus depth plots for all the heat flow stations of this study.

Seventeen temperature stations were achieved with penetration depths ranging from 2.7 to 7.2 m (Table 1). For most of the stations, the duration of stationing was sufficiently long (>20 min) for equilibrium temperatures to be obtained. All the available measurements can be seen in Fig. 3. Note the good consistency of the data within each lake, and the marked difference between the two lakes. The data are believed to be reliable except for stations 4 and 5 where the measurement duration was too short to yield equilibrium conditions. In stations 11 and 17, the estimates of penetration depths seem to be wrong. Above a depth of 4–5 m, temperatures are obviously affected dramatically by seasonal climatic variations.

We now turn to the various corrections which must be applied to these raw data.

The correction for lake-bottom water temperature fluctuations requires the knowledge of the sediment–water interface temperature variations. In the remote highlands of the Tibetan plateau, none of these data are available or easy to obtain. However, climatic records are available over a 20-yr period from the Lang-Ka-Zhe meteorological station close to our lakes (Fig. 1). Figure 4 shows the evolution of the yearly mean temperature over this length of time, as well as the monthly mean air and ground temperatures. The data can be fitted by a simple cosine function with a period of 1 yr (Fig. 4). The lakes do not freeze in the winter season. The external forcing due to weather conditions is regular and it is likely that the lake water temperature varies with the same 1 yr period. In any case, the 1 yr cycle with 8 °C amplitude must be the dominant component of temperature fluctuations.

Fluctuations with shorter periods are possible due to transient water transport phenomena in the lakes, but would be of smaller magnitude and of much smaller depth penetration. For an amplitude T_0 and a pulsation ω, the resulting amplitude of fluctuations at depth z is (ref. 13, p. 63)

$$T_0 \exp\{-(\omega/2\kappa)^{1/2} z\} \quad (1)$$

Considering the high gradients observed, such fluctuations must be smaller than 0.02 °C in amplitude to be considered as negligible. For the main 1 yr cycle, we found that a good estimate for T_0 was 4 °C. From equation (1), this perturbation has no measurable effect at depths >8.4 m. Shorter period fluctuations must be of smaller amplitudes. Taking for example, a 1 °C amplitude and a 6-month period, we find that the effects are significant down to depths of 4 m only.

As a consequence, we assumed that the major correction to be applied is for a 1 yr cycle, with an amplitude smaller than that of the air temperature (T_0) and a time-delay (ϕ) due to the lake response. The formula used for the temperature fluctuations at depth z is:

$$T_0 \exp\{-\alpha.z\} \cos\{(\Pi/6)t - (7.5/6)\Pi - \phi - \alpha z\} \quad (2)$$

where α is equal to $\{\omega/2\kappa\}^{1/2}$, ω is the pulsation ($\Pi/6$) and t is time (in months). The correction was applied to all stations on a trial basis, varying both the amplitude and the delay, until optimum linear profiles were obtained. Parameters used in establishing the best correction were: amplitudes of 3.2–4.0 °C for both lakes, and small delays of 1.3–1.7 months which are not unexpected since the lakes are rather shallow. The extrapolated sediment–water interface temperatures were checked to be uniform in all cases (Table 1). In each lake, a single type of correction was found to correct most of the stations. The corrected gradients are in good agreement with each other, except for station 15 which yields a very high value. We attribute this anomaly to local refraction and topographic effects because this station is close to a small island in Yang-Zho-Yung lake (Fig. 5). No correction could be applied with reasonable success to several stations with shallow penetrations in Yang-Zho-Yung lake. This is probably due to temperature fluctuations with periods smaller than 1 yr, over which we have no control but which have negligible effects on the deeper data points. These stations do not constitute a heavy loss because they are clustered near stations 6 and 10 where reasonable corrections could be applied. A more detailed discussion of these corrections will be reported elsewhere.

Steady-state corrections are made up of corrections for local topography, thermal refraction at the sediment–basement boundary, and the warm-rim effect of the lake.

These effects were estimated numerically using a finite-element computer program. Calculations were done mostly at the Institute of Geology, Academia Sinica, Beijing and some on a different program in Paris. We took seven profiles between 14 and 30 km long, roughly perpendicular to local topographic features, which covered all heat flow stations. Most of these corrections are of small magnitude (<10%) (Table 1).

Transient corrections involve long-term climatic changes, sedimentation rates and uplift and erosion. Using available climatic models for Tibet[14] and the preliminary observation that the lakes have sedimented quietly, the first two corrections are found to be small (~1.7–3.5% and 1.0–2.6% for climatic and sedimentation effects respectively). The correction for uplift and erosion is more difficult to evaluate because we have no good estimates for erosion and uplift rates. We now discuss the implications of these measurements, with due consideration for the remaining uncertainties.

Discussion

Figure 5 summarizes the heat flow values obtained in this study after all corrections excluding those for uplift and erosion. Note the good consistency of the values within each lake. Given the magnitude of measurement errors which is certainly larger than

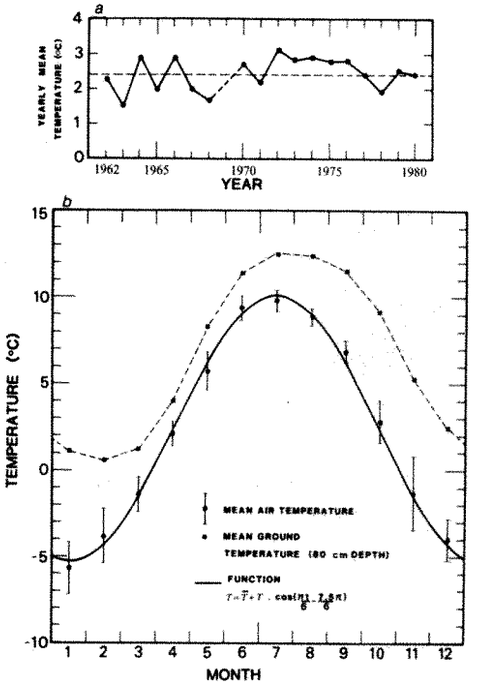

Fig. 4 *a*, Evolution of the yearly mean temperature at the Lang-Ka-Zhe meteorological station. *b*, Evolution of the air and ground temperature (at 80 cm depth) over a period of 1 yr. The air temperature data is made of average monthly values over 20 yr (bars represent ±1 s.d.). Also shown is the simplest cosine function which fits these data.

10% (a representative value for the conventional oceanographic technique), the data do not provide any evidence for a significant variation of heat flow within Yang-Zho-Yung Lake. Our measurements show that heat flow rises sharply from 91 to 146 mW m^{-2} in ≤25 km, and remains approximately constant over a distance of 30 km towards the Yarlung–Zangbo suture zone (Fig. 6). There are *a priori* three possible explanations for such high heat flow values: high heat production, an anomalous heat source (magma), or an anomalous mantle heat flow. A detailed interpretation of the data requires a proper understanding of: (1) uplift and erosion; (2) the regional thermal structure and its evolution with time; and (3) the age of the hypothetical intrusion or melting event. More extensive thermal modelling will be reported elsewhere.

The uplift problem is probably the most crucial one. Several authors have argued on palaeontological evidence and fission track studies[3] that the uplift is recent (2 Myr) and fast (0.2 cm yr^{-1}). Such fast uplift rates could increase the heat flow values by as much as 60%. However, some of these estimates depend on an assumed thermal regime and the reality of such a dramatic pulse remains questionable. The India–Asia collision has been occurring for ~45 Myr (ref. 15) and there is no obvious reason why a major change in tectonic regime occurred 2 Myr ago. Typical epeirogenic uplift rates in active regions are of the order of 0.2 mm yr^{-1} (ref. 16), which would spread out in time the plateau uplifting, making it more compatible with the overall evolution of the region. In such a case, the uplift effect would be much smaller, around 20%. However, these corrections were estimated in the usual fashion (ref. 13, p. 338) and, in the very transient thermal state of Tibet, are of little interpretative value.

Erosion effects must also be taken into consideration. In the absence of any information concerning the shaping of the present terraine morphology, it is impossible to estimate the effects of local and recent erosion, such as those discussed by England[7]. In the plateau environment, they are probably small because local topography is very subdued, as witnessed by the small magnitude of the topographic correction (Table 1). Relief is more pronounced near sites 6 and 10 in Yang-Zho-Yung Lake. However, these stations yield values which are comparable to

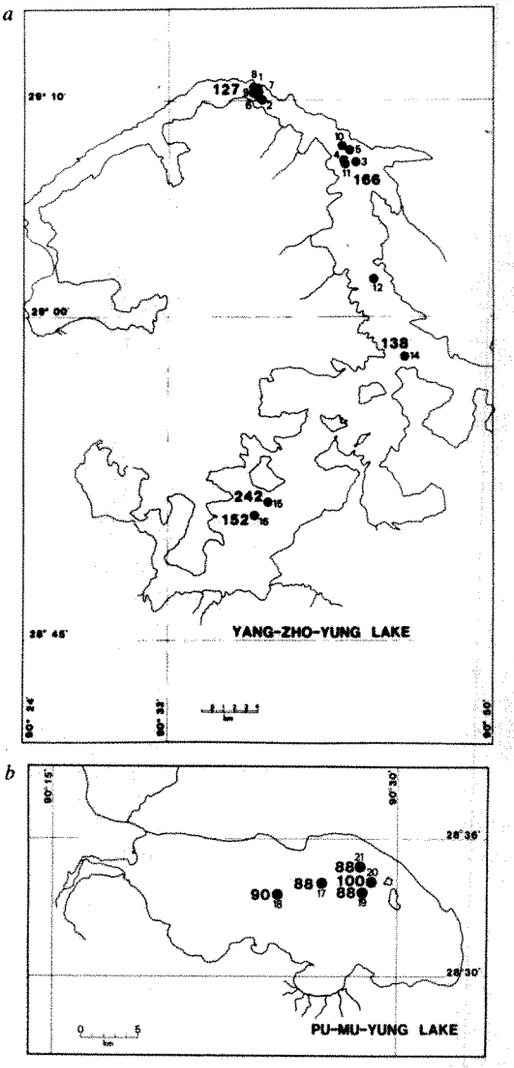

Fig. 5 *a*, Heat flow stations (small numbers) and values (large numbers) in Yang-Zho-Yung lake. Heat flow values are in mW m^{-2} (not corrected for uplift and erosion, see text). *b*, As *a* for Pu-Mu-Yung lake.

those from stations 14 and 16, 20 km away to the South where local topography is negligible (<70 m). We believe that the difference between the heat flow values for the two lakes is real. As will be stated later, electromagnetic measurements yield evidence for a discontinuity at the same location. The regional erosion of the Tibetan highlands is more of a problem. It represents an additional increase of heat flow, as it corresponds to a vertical advection of hot material (see, for example, ref. 17).

Note that in the extreme conditions prevailing here, the usual procedure for 'correction' is not valid. It is designed to account for transient effects which are significant at shallow depths only in otherwise steady-state conditions and to allow the calculation of representative geotherms. In the case of Tibet, we must take into account the full transient thermal evolution of the region, including crustal shortening and the resulting stretching of geotherms[18] as well as regional cooling due to the underthrusting of cold continental lithosphere.

At any rate, such regional phenomena must affect all heat flow values and cannot account for the sharp spatial variation which is observed. Even if the maximum correction of 60% is applied, the Yang-Zho-Yung values would still be high by continental standards: at 58 mW m^{-2} they would clearly stand above 'equilibrium' regions where the mean heat flow is 46 mW m^{-2} (ref. 19). This difference is not due to anomalously high heat production. There are few radioactivity determinations on Tibetan rocks. The available data from basement material

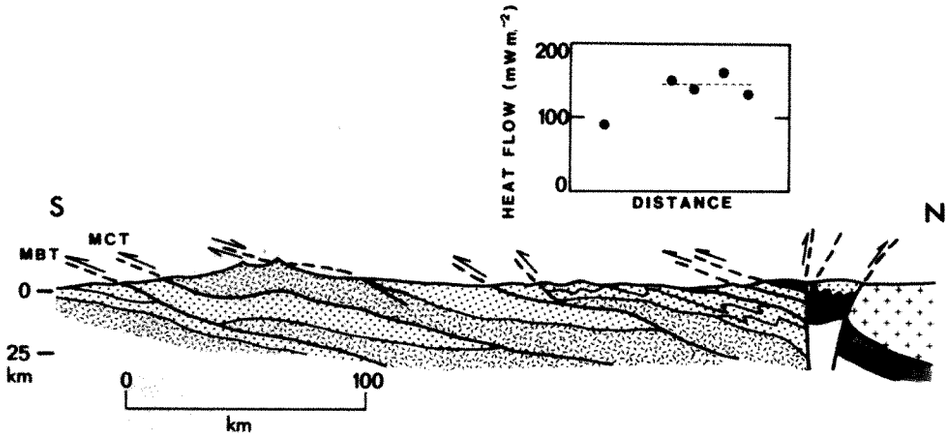

Fig. 6 Schematic cross-section perpendicular to the Yarlung-Zangbo suture zone (from ref. 15). Crosses and dots indicate granitic and sedimentary formations. The stippled and grey patterns are for basement and ophiolite rocks. The heat flow values are shown at their respective locations.

which outcrops to the West of our lakes (Fig. 1) indicate a value of 2.7 $\mu W\,m^{-3}$ for the heat production rate[20]. This value is normal for old continental formations, and, according to empirical heat flow/heat production relations, corresponds to heat flow values around 45 $mW\,m^{-2}$ (see, for example, ref. 19).

One explanation for the high heat flow values would be that because the crust is anomalously thick, there is a larger amount of radioactive elements beneath the plateau. Considering an average heat production of 0.7 $\mu W\,m^{-3}$ for continental crust material[21], it would take a thickness of 140 km to yield a radiogenic contribution of 100 $mW\,m^{-2}$ to the surface heat flow (that is corresponding to an observed average heat flow of 125 $mW\,m^{-2}$). Furthermore, we would also have to explain why heat flow increases so rapidly between the two lakes. Similarly, an anomalous mantle heat flow is not a suitable hypothesis because it should have a regional effect. Even if it was localized in a narrow zone below the lithosphere, it could not create a sharp horizontal variation because of the masking effect of the plate.

The most likely explanation is therefore that there is a source of heat in the crust which terminates abruptly somewhere between the two lakes. Such a discontinuity at this particular spot was also found from magneto-telluric soundings carried out in the same area[21]. This anomalous source of heat is most probably a hot intrusive body. To model the associated thermal effects would require some knowledge about the time of emplacement or melting: a recent event must be shallow to be detectable by surface heat flow measurements. The conductive time scale is $\tau = d^2/4\kappa$, where d is the depth to the anomaly and κ thermal diffusivity. Because the intrusive or melting event must somehow be associated with the underthrusting of India beneath Asia, it must be younger than 45 Myr[15,22,23] and must therefore be shallower than ~70 km (using a κ of $10^{-2}\,cm^2\,s^{-1}$). The Makalu granite in the Himalayan range has been recently dated at about 21 My[24]. This is evidence that melting conditions have been reached in the Tibetan crust after India collided with Asia.

From the value of 146 $mW\,m^{-2}$ and the maximum range in corrections, it is possible to give a rough estimate of the depth to the anomalous body. Assuming steady-state conditions and a standard radioactivity model (see ref. 19), and taking the 600 °C isotherm as a reference for crustal solidus temperatures (for hydrated material such as sediments), we find that this depth must be between 10 and 25 km. Allowing for transient effects, these estimates must be considered as upper bounds. A conservative conclusion is therefore that the heat source must be shallower than 25 km. Such small crustal depths would indeed yield a sharp horizontal variation of heat flow in the vicinity of the body edge. The horizontal distribution of heat flow allows some further constraints on the timing and depth of the intrusive or melting event which will be developed in a future paper.

Our data yield no evidence for any significant heat flow variation over a distance of ~30 km (Fig. 6). This suggests that the heat source is of large horizontal dimensions. If this source is also the cause of the widespread geothermal activity of the plateau, it is not surprising that it has large horizontal dimensions. This would agree with geological observations made in old continental collision zones which typically exhibit tabular granitic formations extending over whole provinces[24].

Sharp horizontal heat flow variations are reminiscent of other tectonically active regions such as the southwestern United States[25,26] or geothermal areas[27]. Finally, note that the heat flow increase occurs at a distance of about 230 km from the main locale of underthrusting (Fig. 6). This is typical of subduction environments where high heat flows and volcanic activity show up abruptly at similar distances from trenches[28].

The measurements reported here suggest that regional melting conditions are reached at relatively shallow crustal depths in Tibet. This represents a powerful contraint for thermo-mechanical models of continental collisions.

The field work was funded by CNRS and INAG (France) and the Chinese Academy of Geological Sciences and Academia Sinica (China). It would not have been possible without the loan of heat flow and coring equipment by CNEXO and GENAVIR. We thank C. Allegré, chief scientist of the French expedition, for his encouragements in setting up this project. Professor Shau Shu Chang was the chief scientist of the Chinese party. We thank H. Lossouarn for help in the field, J. P. Foucher, R. Conogan, C. Toularastel and J. Le Pavec for assistance in preparing the Tibetan cruise and K. Kelts for advice. We also thank the Math Geology Research Group at the Institute of Geology, Academia Sinica, Beijing. We acknowledge the important logistical support provided by the People's Liberation Army and all the individuals who helped us in the field.

Evolution of the genes for the β subunits of human chorionic gonadotropin and luteinizing hormone

Karen Talmadge*, Nikos C. Vamvakopoulos* & John C. Fiddes*

Cold Spring Harbor Laboratory, PO Box 100, Cold Spring Harbor, New York 11724, USA

Nucleotide sequence comparisons of the single gene for the human luteinizing hormone gene β subunit with two of the seven genes for the human chorionic gonadotropin β subunit suggest that the β human chorionic gonadotropin genes have evolved from an ancestral β luteinizing hormone gene by a series of selected changes with very little neutral drift. Moreover, the 24 amino acid carboxy-terminal extension of the human chorionic gonadotropin β subunit appears to have arisen by a single base deletion that incorporated the 3'-untranslated region of the ancestral β luteinizing hormone gene into the coding region.

HUMAN chorionic gonadotropin (HCG) and luteinizing hormone (LH) are two members of the glycoprotein hormone family. The two hormones are very similar both functionally and structurally, although they are expressed in different tissues and at different developmental stages. Luteinizing hormone is made in the pituitary and has a central role in promoting spermatogenesis and ovulation by stimulating the testes and ovaries to synthesize steroids. In contrast, HCG is made by the first trimester placenta and stimulates the ovaries to synthesize the steroids that are essential for the maintenance of pregnancy. Nevertheless, both hormones bind to the same testicular and ovarian receptors (for a review of the biochemistry of these hormones, see ref. 1).

In common with the other members of the glycoprotein hormone family, HCG and LH are dimeric with two dissimilar, noncovalently associated subunits, α and β. The α subunit is common to all the glycoprotein hormones[1] and, in humans, is encoded by a single gene which has been isolated and characterized[2–4]. Unlike the α subunit, the β subunits are unique to each hormone and confer biological specificity. However, in keeping with their closely related biological functions, β-HCG and β-LH have an 82% amino acid sequence homology[5–9].

We isolated a cDNA clone for the β subunit of HCG[10] and used this to examine the structure and chromosomal organization of the genes for the β subunits of HCG and LH. We found that the β-HCG and β-LH genes were linked[11] and that the latter was encoded by a single gene[12]. In contrast, we found that β-HCG is encoded by seven genes or pseudogenes[11,12] which, together with the single β-LH gene, were shown to have an unusual structural organization of genes arranged in tandem and inverted pairs[11]. Figure 1 summarizes these data.

We present here the complete nucleotide sequences for the single β-LH gene and for two of the β-HCG genes, those numbered 5 and 6, which were chosen because they form one of the two inverted gene pairs (see Fig. 1) and we were interested in the possible implications of this symmetrical arrangement for gene expression. The strategies used to determine the sequences are shown in Fig. 2 and the sequences, aligned with respect to each other, are shown in Fig. 3. Comparison of these sequences suggests that the β-HCG gene evolved from an ancestral β-LH gene by a series of selected changes with very little neutral genetic drift. The sequence comparison also shows that the carboxy-terminal extension of the β-HCG subunit protein arose, as we previously predicted[10], by a readthrough event in which the 3'-untranslated region of the β-LH gene became incorporated into the coding region. This readthrough could have been caused by a single base deletion.

Origin of the HCG gene

Luteinizing hormone is synthesized in the pituitaries of a wide range of species. In contrast, chorionic gonadotropin is found only in the placenta of certain mammals such as horses, baboons and humans[1,13,14], and is thus considered to be the most recently evolved member of the glycoprotein hormone gene family. Due to the strong structural and biological similarity between LH and HCG, it has been suggested previously that the β-HCG gene arose directly from a β-LH or β-LH-like ancestral gene[15].

The β subunit of HCG is 24 amino acids longer than the β subunit of LH. Alignment of the two β subunit amino acid sequences shows that the extra 24 amino acids of the HCG β subunit form a carboxy-terminal extension that is unique to β-HCG. We suggested previously[10] that this carboxy-terminal extension resulted from a readthrough event in which the β-HCG gene evolved from its β-LH gene ancestor by incorporation of the 3'-untranslated region into the coding sequence. This suggestion was based on the observation that the cDNA

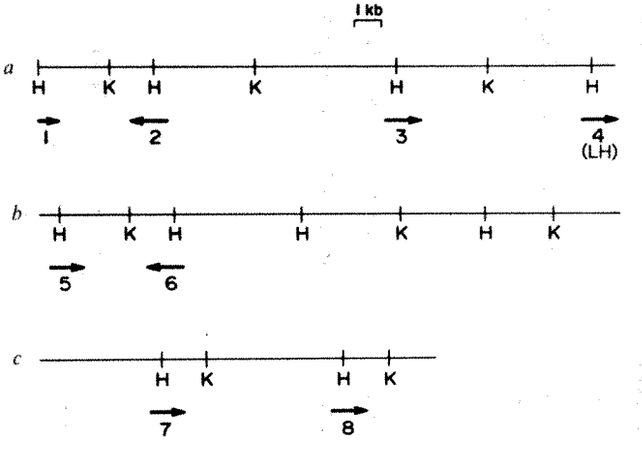

Fig. 1 Organization of the three groups, *a*, *b* and *c*, of cloned sequences that hybridize to the β human chorionic gonadotropin cDNA probe. The positions of the eight genes (4 is the single β luteinizing hormone gene) are shown by arrows pointing in the putative directions of transcription. Locations of sites for the restriction enzymes *Hin*dIII (H) and *Kpn*I (K) are shown. The identification of these genes was established in refs 11 and 12. The map is adapted from ref. 11.

Table 1 Gene sequence comparisons

Gene pairs	Replacement changes No.	Replacement changes %	Silent changes No.	Silent changes %	Intron changes No.	Intron changes %
LH:CG5	19/296.7	6±2	7/101.3	7±3	24/545	4±1
LH:CG6	19/296.7	6±2	8/101.3	8±3	32/545	6±1
CG5:CG6	1/369	0.3±0.3	1/123	1±1	18/545	3±1
HGH:HPL	33.5/482	7±1	18.5/161	11±3	72/726	10±1
RI:RII	8/249.2	3±1	15/80.8	19±5	21/99	21±5
RBG:MBG	35/330	11±2	49/110	44±6	120/267	45±4

Genes compared: LH, β luteinizing hormone; CG5, β human chorionic gonadotropin gene 5; CG6, β human chorionic gonadotropin gene 6; HGH, human growth hormone; HPL, human placental lactogen; RI, rat preproinsulin gene I; RII, rat preproinsulin gene II; RBG, rabbit β globin; MBG, mouse β globin. The values for the RI:RII and RBG:MBG comparisons are taken from ref. 20, all other values were calculated by the method given in ref. 20. The fractions (%) are the number of actual substitutions divided by the number of potential substitutions of a given type. The standard deviations were estimated as the square root of [the fractional change (%) divided by the number of potential changes]. The data are not corrected for possible multiple substitutions. The two LH:CG comparisons were made over the homologous coding regions from the start codons at position 553 up to, but not including, the single base deletion in the CG genes that is responsible for the frameshift. The CG5:CG6 comparison is over the 164 residue signal sequence and mature protein encoding regions. The HGH:HPL comparison is over their 210 residue signal sequence and mature protein encoding regions.

for the β subunit of HCG had a particularly short 3′-untranslated region of 16 nucleotides and that the termination codon of β-HCG was the TAA sequence of the polyadenylation signal AATAAA[16].

We can now identify the nucleotide changes that caused the readthrough. A single base deletion at position 1,540 puts the β-HCG sequence out of frame with the last seven codons of β-LH and allows the 3′-untranslated region to become incorporated into the coding region. In addition to this, a two base pair (bp) insertion at positions 1,612 and 1,613 in the β-HCG sequence allows the carboxy-terminal extension to continue to the termination codon, TAA. Without this 2 bp insertion, the β-HCG carboxy-terminal extension would be eight amino acids shorter, ending with a TGA termination codon. If the 2-base insertion occurred first, it would have been a neutral mutation as the inserted bases would still be part of the 3′-untranslated region. If the single base deletion occurred first, then the β-HCG coding sequence has undergone two carboxy-terminal extensions, but we consider this unlikely. Nevertheless, by either mechanism, the primary event that led to the incorporation of the 3′-untranslated region into the coding region was the single base pair deletion. We note that the β-LH termination codon, put out of frame in the β-HCG gene, has been lost by a single base change, but we do not think that that could have been the initial event leading to the carboxy-terminal extension because there is no other terminator in the 3′-untranslated region in frame with it.

Thus, the β subunit of HCG has acquired 8 amino acids by translation in a new reading frame, and 24 amino acids from a previously untranslated region. This has occurred without any substantial change other than the frameshift mutations as β-HCG genes 5 and 6 are 90% homologous with the β-LH gene over the region encoding the carboxy-terminal extension, nucleotides 1,541–1,634. The function of this carboxy-terminal extension is not known as HCG appears to bind to the same membrane receptors and to elicit the same response as LH. However, HCG is 10 times more stable than LH, and it has been suggested that the carboxy-terminal extension has a role in this (see ref. 13 for a review).

Nucleotide changes

We suggested previously[11,12] that the β-HCG gene arose by a duplication of an ancestral gene. This duplication was followed by a series of changes, including the frameshift mutations, which generated the new β-HCG function. Once this new function was established, the β-HCG gene itself duplicated and rearranged to give the present complex organization (see Fig. 1). The nucleotide sequences we have established here provide information on the series of changes that took place as the newly duplicated ancestral gene evolved into that for β-HCG.

To compare the nucleotide sequence differences between the β-LH gene and the two β-HCG genes 5 and 6, we have calculated the per cent divergence between the introns, and between replacement and silent substitution sites across the homologous coding regions. These data are shown in Table 1. Table 1 also shows similar calculations for a selection of other gene pairs, including the two β-HCG genes themselves, human growth hormone (HGH) and human placental lactogen (HPL) genes[17–19], the two rat preproinsulin genes I and II[20], and the rabbit and mouse β-globin genes[21,22].

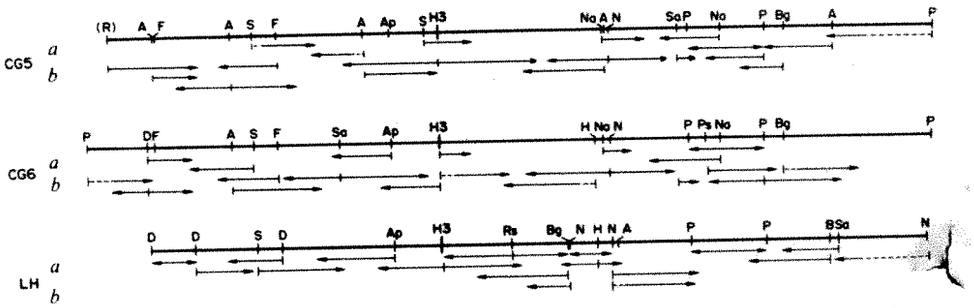

Fig. 2 Nucleotide sequencing strategy for the β-HCG genes 5 and 6 (CG5 and CG6) and the β-LH gene. Arrows mark the restriction sites sequenced from and the extent of the individual sequence determinations, the dotted portions of the arrows indicating where the sequence was not read immediately adjacent to a labelled site. Restriction enzyme sites used in the sequence determination are marked. A, *Ava*I; Ap, *Apa*I; B, *Bgl*I; D, *Dde*I; F, *Hin*fI; H, *Hin*cII; H3, *Hin*dIII; N, *Nco*I; Na, *Nae*I; P, *Pvu*II; (R), *Eco*RI (generated by an *Eco*RI linker); Rs, *Rsa*I; S, *Stu*I; Sa, *Sac*I. The nucleotide sequence of β-LH gene shown in Fig. 3 includes the area marked by solid arrows. The nucleotide sequences of β-HCG genes 5 and 6 shown in Fig. 3 begin about 100 bp after the solid arrows above. Both the chain termination method (*a*) and the chemical degradation method (*b*) were used. For chain termination sequencing[36], purified fragments were blunt-ended and cloned into the unique *Sma*I site of M13mp8[37]. A 17 bp synthetic primer was purchased from P-L Biochemicals. Chemical sequencing[38] was performed on fragments labelled at their 3′ ends with [α-^{32}P]-deoxynucleoside triphosphates and the Klenow fragment of DNA polymerase I. All restriction enzyme sites were overlapped in the β-HCG gene 5, but in the cases of β-HCG gene 6 and the β-LH gene, the overlap at one and two sites respectively was done by analogy with the β-HCG gene 5.

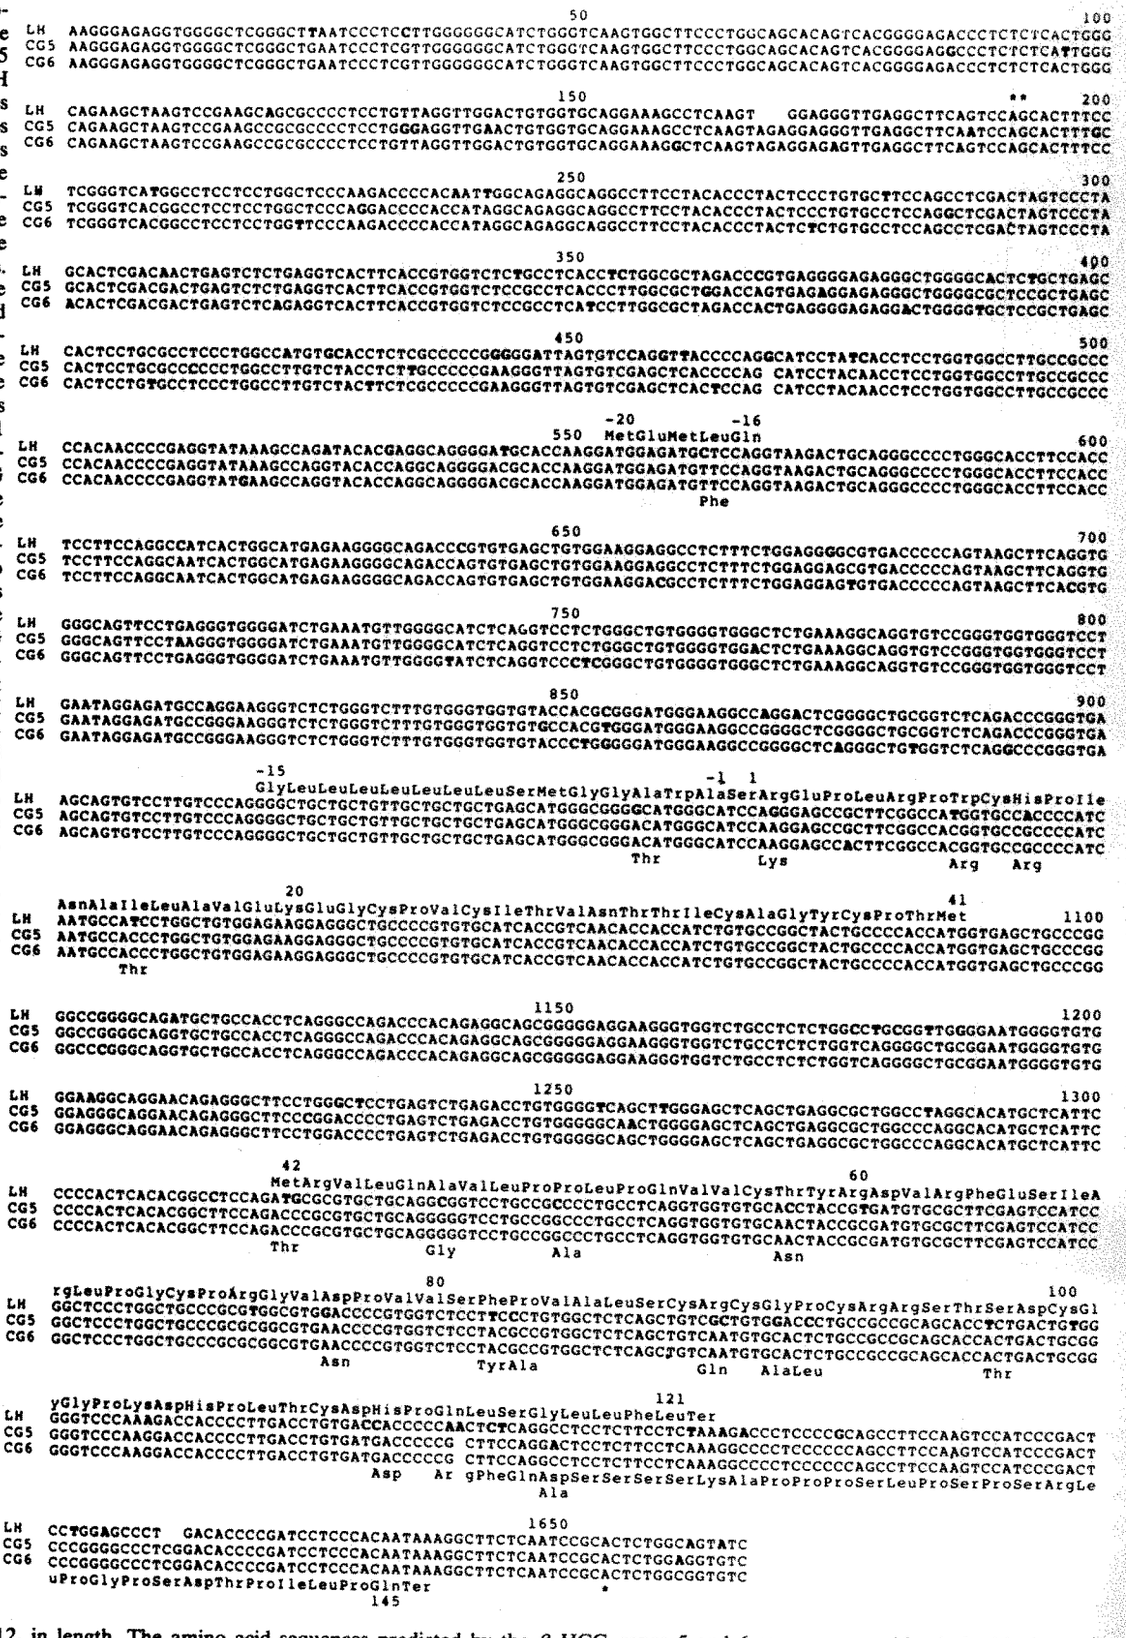

Fig. 3 The complete nucleotide sequences of the β-HCG genes 5 and 6 (CG5 and CG6) and the β-LH gene. The three sequences have been aligned with gaps where there are deletions and insertions, and the nucleotide sequence numbers, immediately above the nucleotide sequences, are not adjusted for deletions. In the alignment of the nucleotide sequences, bold face letters indicate positions where one of the three sequences differs from the other two. The two asterisks at nucleotides 190 and 191 identify the proposed transcriptional start for β-HCG (unpublished data), and the single asterisk at nucleotide 1,654 marks the polyadenylation site. The amino acid sequence of β-LH is shown above the nucleotide sequence. For the β-HCG genes 5 and 6, only the predicted amino acids that differ from those of β-LH are shown below the nucleotide sequences. Amino acid numbers are placed immediately above amino acid names, and negative numbers refer to amino acids in the signal peptide. The β-HCG genes 5 and 6 introns were located by comparison with the β-HCG cDNA sequence[10]. The β-LH gene introns were located by homology with the β-HCG gene sequences. The sequences at the intron–exon boundaries show the expected homologies with those in other systems[39–41]. The β-LH amino acid sequence derived from our nucleotide sequence differs from the published sequence[5,9], in that there is a Met–Met and a Val–Val at positions 41–42 and 55–56, respectively, rather than the single methionine and valine residues previously reported[5,9], bringing the β-LH protein sequence into register with that of β-HCG. Also, the carboxy-terminus is seven amino acids longer than previously reported[9], making the human β-LH sequence more homologous to the ovine, porcine and bovine sequences[42–44] and 121 residues, rather than 112, in length. The amino acid sequences predicted by the β-HCG genes 5 and 6 sequences are identical with the exception of position 117, which is aspartic acid in gene 5 and alanine in gene 6. This position is aspartic acid in both the published amino acid sequences from two groups[7,8] and in our cDNA sequence[10]. The β-HCG genes 5 and 6 have a single silent change in codon 4; our cDNA sequence[10] and β-HCG gene 5 agree. The nucleotide sequence of the β-HCG gene 5 is identical with that of the published cDNA sequence with two exceptions: nucleotide position 529 is a C in the gene sequence and a G in the cDNA sequence (this nucleotide is close to the 5′ end of the cDNA clone, and presumably was misincorporated by reverse transcriptase, as has been observed in other systems[45]), and nucleotide position 1,589 is a T in the gene sequence and a C in the cDNA sequence (this is a silent third position change and is an error in the published cDNA sequence[10]).

Striking differences emerge from these comparisons. For the preproinsulin and β-globin gene pairs, the rates of intron and silent position divergence are similar within each pair, and are four to seven times greater than the rate of replacement changes. Similar results have been obtained with a further 42 gene pairs encoding identical functions and a further 4 gene pairs encoding different functions[23,24]. In marked contrast, the replacement and silent sites of the two β-HCG genes have diverged from those of the β-LH gene at similar rates, between 6 and 8%, whilst the introns of each pair have diverged slightly less, between 4 and 6%. Thus, unlike most other gene pairs, the replacement, silent and intron changes have all occurred at approximately equal rates. The introns and silent sites of the HGH/HPL gene pair have also diverged at rates that are only slightly higher than the rate of replacement changes. It is interesting that the HGH/HPL gene pair is analogous in this respect to the β-HCG/β-LH gene pair: both proteins in each of the pairs have similar functions, but one (HGH/HPL) is synthesized in the pituitary while the other (β-HCG/β-LH) is synthesized in the placenta. A high rate of replacement, compared with neutral, changes has also been observed in a pair of rabbit globin alleles[21,25,26] and a pair of immunoglobulin light-chain genes[27], and in cDNA fragments encoding the carboxy-terminal thirds of two mouse H-2^d antigens[28].

Discussion

How can we explain the high rate of replacement, compared with neutral, changes between the β-LH/β-HCG and the HGH/HPL gene pairs? One theory of evolution holds that observed changes in protein structure are spread through the population by selection[29–31]. In support of this hypothesis, Perler *et al.*[23] cite the two rabbit β-globin alleles[21,25,26], between which there are four replacement changes with no silent changes and only two intron changes, as a clear example of selection. They assumed that these changes were fixed so rapidly by selection that there was no opportunity for neutral changes to appear. This could be the case for the reported immunoglobulin light-chain[27] and H-2^d antigen[28] gene pair comparisons, although the generation of polymorphisms in these systems may be a specialized and, at least in the case of the immunoglobulin light chains, perhaps distinct mechanism. The selection argument of Perler *et al.*[23] can also be applied to the evolution of the new functions in the β-HCG/β-LH and HGH/HPL gene pairs.

An alternative interpretation of the high rate of replacement, compared with neutral, changes in the evolution of the β-HCG from a β-LH gene is that genes evolve first by fixation of the new function (selection), followed by accumulation of neutral changes (drift). By this hypothesis, the evolution of β-HCG is the most recent event yet analysed, more recent than the evolution of HPL. Like the β-chorionic gonadotropin and β-LH genes, the GH and PL genes diverged late in mammalian radiation[32], but which gene family diverged first is not known because systematic cross-species protein comparisons either for chorionic gonadotropin or PL have not been done yet.

The neutral mutation–random drift theory[33–35] holds that most observed changes in amino acid sequence are neutral and are fixed in the population by random drift. Unless the β-HCG genes duplicated very recently, it is difficult to imagine how so many replacement changes could have taken place between the β-HCG and β-LH genes by neutral drift, given that so few replacement changes have been allowed between the two β-HCG genes. It is unlikely that the β-HCG genes duplicated recently compared with the original β-LH gene duplication, because the rate of divergence of the intron sequences of β-HCG genes 5 and 6 approaches those of the β-LH/β-HCG gene pairs.

From the rapid rate of replacement relative to neutral changes in the evolution of β-HCG from β-LH, and the low level of replacement relative to intron changes between the two β-HCG genes, we conclude that selection of a new function is the mechanism most consistent with the observed sequence differences. If stability is truly the only difference between HCG and LH, then the changes across the homologous coding region, and not just the carboxy-terminal extension, must be involved. However, we believe that there may be other, as yet unidentified, functional differences between chorionic gonadotropin and LH that require the observed coding differences. Moreover, because the divergence between the two β-HCG intron sequences approaches the divergence between the introns of the two β-LH/β-HCG gene pairs, we suggest that the β-HCG gene duplications and rearrangements occurred soon after the establishment of the new β-HCG function.

This work was supported by a grant from the NIH. We thank M. DeLuca for technical assistance, Computer Technology, Limited, for the computer print-out of the sequences, our colleagues at Cold Spring Harbor Laboratory for their valuable advice and discussions, and T. Jukes, B. Cordell, P. Kushner and B. McCarthy for helpful comments on the manuscript. K.T. was a postdoctoral fellow supported by a grant from the Ford, Rockefeller and Mellon Foundations.

Recurrent bursts in GBS0526−66, the source of the 5 March 1979 γ-ray burst

S. V. Golenetskii, V. N. Ilyinskii & E. P. Mazets

A. F. Ioffe Physical-Technical Institute, 194021 Leningrad, USSR

The results of the observations of GBS0526−66 during 1979[1–3] have been reviewed[4] recently primarily in the context of its possible identification with the N49 supernova remnant in the Large Magellanic Cloud (LMC). Observations in 1981 and 1982, however, reveal a still more complex pattern of behaviour and show both that the nature of this source of the 5 March 1979 event and its true position in space are far from being clear. Observations from Veneras 13 and 14 reveal that GBS0526−66 continues to generate weak recurrent γ-ray bursts. Thus the transient object which during the 5 March burst behaved for several minutes as a flaring X-ray pulsar[1] has since then been exhibiting a peculiar similarity with a hard X-ray burster.

γ-Ray burst observations from Veneras 13 and 14 started in November 1981. The Konus instrument used is a modified version of the one flown on Veneras 11 and 12 (ref. 5). The time resolution and recording time essential for the burst time profile measurements have been improved. Apart from this, Venera 13 can now measure 16 energy spectra consecutively. While Venera 14 obtains eight consecutive spectra as before, the number of the energy channels in each spectrum has been increased to 30. In both cases the accumulation time for the first two spectra is 0.5 s; the subsequent spectra are averaged over 4 s, as before.

The first two recurrent bursts originating in GBS0526−66 were recorded on 1 December 1981 and 2 January 1982 [6]. The time profiles and energy spectra of these events are shown in Fig. 1, the profiles being drawn with a 1/32 s time resolution. They reveal short rise and decay times. From the available recordings with a 1/256 s resolution one may conclude that the rise times here are $\tau_r < 30$ ms.

No spectral variability has been found within experimental accuracy. Therefore for GB811201 we present a net spectrum summed over three consecutive measurements 0.5, 0.5 and 4 s long, while for the shorter burst GB820102a the sum of the first two spectra accumulated in 0.5 s each is shown. The incident photon spectra were obtained by the usual procedure of unfolding the experimental energy loss spectra using the sensitivity matrix of our detectors. Figure 1 shows the spectra in energy units. The spectra are seen to approximate the relationship $dI(E)/dE \propto \exp(-E/kT)$ with the temperature kT, accordingly, 31 ± 2 and 26 ± 3 keV.

Ten more weak recurrent bursts from the same source have subsequently been recorded on the two spacecraft. The time profiles of some of these bursts are shown in Fig. 2. Because the spectra of these weak events were measured with a poor statistical accuracy, we do not present here the corresponding graphs. However, the data obtained clearly indicate that these spectra resemble one another and correspond to an emission temperature ≈35 keV.

Localization of these bursts was carried out by the usual procedure in the Konus experiment when recording an event at the two spacecraft[5]. The difference in the arrival times yielded a triangulation ring, the section containing the source being determined by analysing the anisotropic angular sensitivity of the detectors. Three events were detected only on Venera 13. The weak burst GB820921 did not trigger the recording on Venera 14. During the two other events, GB830321 and GB830405, the γ-ray burst detector on Venera 14 was switched off. These weak events were localized by the angular anisotropy technique with a low accuracy of ~15°. The crude localization data, the shape of the time profiles and of the spectra suggest that these three events similarly belong to a general sequence of recurrent bursts.

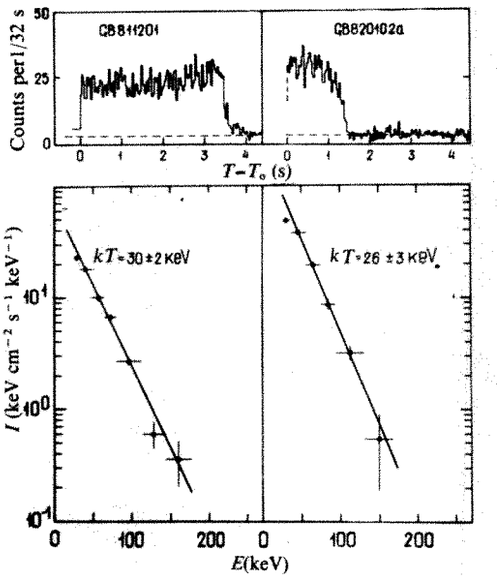

Fig. 1 Time profiles (top) and energy spectra (below) of the γ-ray bursts on 1 December 1981 and 2 January 1982. The horizontal dashed line in the time profiles shows the background level.

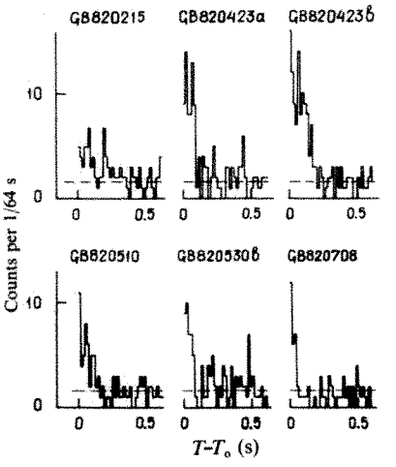

Fig. 2 Time profiles of the weak recurrent bursts from the GBS0526−66, February to July 1982.

The localization regions of 13 recurrent bursts from the GBS0526−66 observed in the Konus experiment on Veneras 11 and 12 in 1979 [7,8] and Veneras 13 and 14 in 1981–83 are presented in Fig. 3. All the localization regions are seen to intersect within a very small area of the sky which contains the most precise position for the 5 March 1979 event[9] denoted with a cross.

The sequence of bursts of 1979 followed the powerful event of 5 March. Between our observations on Venera 11 and 12 and on Venera 13 and 14 there was a break from February 1980 to November 1981. The question may arise of whether the recurrent burst sequence of 1981–83 was preceded by as powerful an event. Apparently this was not the case. The 5

March event was detected on at least nine spacecraft[4]. An analogue of such an event could hardly have escaped observation. More probably, during the break in our observations several weak recurrent bursts occurred. However, a possible loss of a series of recurrent bursts cannot substantially alter the observed pattern of behaviour of the GBS0526−66. We see that the transient object which manifested itself in the 5 March event as a flaring X-ray pulsar reveals afterwards a certain similarity to a hard X-ray burster.

The major characteristics of the recurrent bursts are listed in Table 1 which contains the date and detection time T_0 of an event on the two spacecraft, burst duration T_b, emission temperature kT, peak count rate N_{max} and total intensity S. Also given are the coordinates α, δ of the triangulation ring centre, that is the direction of the line connecting the two spacecraft, the radius of the ring, its width $\theta \pm \Delta\theta$ and the minimum distance Δ to which the ring approaches the most precise position for the 5 March event.

These data reveal two remarkable features. First, the energy spectra of all the recurrent bursts have practically the same shape and are characterized by very close values of the temperature kT. Furthermore, they are very close to the spectrum of the soft component in the two-component spectrum of the narrow initial pulse in the 5 March 1979 burst and to that of the 8-s period pulsating radiation in its late stage[8].

Second, the maximum count rate N_{max} in the recurrent bursts and, hence, the maximum luminosity of the source L_{max} also varies only slightly from event to event. Indeed, N_{max} does not differ within the error limits from the mean over all recurrent bursts which is 13 photons in 1/64 s. This count rate corresponds to the flux $I(>30\ \text{keV}) = 10^{-6}\ \text{erg cm}^{-2}\ \text{s}^{-1}$. Only in the first recurrent burst GB790306 does the maximum flux exceed this value by a factor of two. At the same time the scatter in the values of the total intensity S is much larger, namely by about a factor of 40. These differences are determined essentially only by the different duration of the bursts T_b.

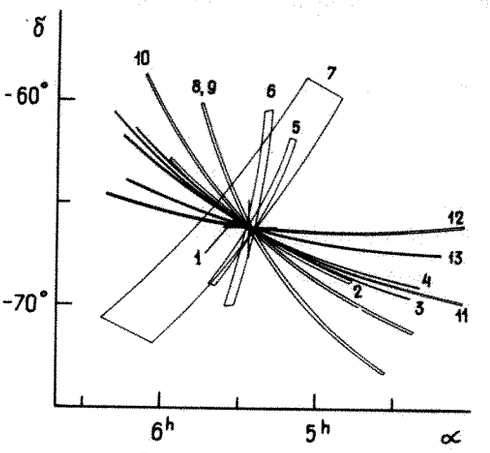

Fig. 3 Localization error boxes for the following events: 1, 5 March; 2, 6 March; 3, 4 April; 4, 24 April 1979; 5, 1 December 1981; 6, 2 January; 7, 15 February; 8 and 9, 23 April a and b; 10, 10 May; 11, 30 May; 12, 8 July; 13, 31 December 1982. The cross shows the most precise localization of the GBS0526−66 (ref. 9).

The 5 March 1979 event and views on its nature have been widely discussed (see review in ref. 4). New observations of the activity of this source show that the burst recurrence represents one of the most essential characteristics of its behaviour. Therefore these new data should prove to be important in the search for an explanation of the nature of the source. In particular, they provide a new argument against its identification with the N49 supernova remnant in the LMC at a distance $d = 55$ kpc.

* The data presented are for the initial burst pulse, whose spectrum consist of two (one hard and one soft) components. For the pulsating phase $S = 10^{-3}$ erg cm^{-2} (ref. 7), $kT = 35.5\pm1.0$ keV (main pulse sequence) and 31.5 ± 1.0 keV (interpulses)[8].

If one compares the limitation on the maximum source luminosity observed in all the recurrent bursts with the Eddington luminosity limit for a neutron star, $I_{Edd} \sim 10^{38}$ erg s^{-1}, then from the measured maximum fluence in the recurrent bursts, $I = L_{Edd}/4\pi d^2 \sim 10^{-6}$ erg cm^{-2} s^{-1}, one can derive an estimate for the distance to the source, $d \sim 1$ kpc. Moreover, it is only natural to assume that the recurrent bursts, just as the 5 March event, are generated in the vicinity of the neutron star's magnetic poles. In this case the emitting region will constitute only a small fraction of the total surface of the neutron star, $f \sim 10^{-2}$–10^{-3}, the total source luminosity being determined by the quantity $L_{max} = fL_{Edd} \sim 10^{35}$–$10^{36}$ erg s^{-1}. Accordingly, the estimate of the distance to the source will become reduced down to $d \sim$ 30–100 pc.

We conclude that the continuing activity of the GBS0526−66 opens up the possibility of looking for recurrent bursts in other, primarily the soft X-ray and visible spectral regions. If these observations are successful, they may be invaluable for helping to solve one of the most intriguing problems in γ-ray astronomy.

The study of metal–oxide interfaces using sputter ion plating

G. C. Allen & R. K. Wild

Central Electricity Generating Board, Berkeley Nuclear Laboratories, Berkeley, Gloucestershire GL13 9PB, UK

The interface between solids has always been difficult to characterize. It is possible to use analytical techniques to probe through an outer surface but matrix effects within the penetrated solid often modify the results to the extent that the interface becomes difficult to detect. The progressive analysis and removal of layers of material from an outer surface until the interface is reached may prove useful but during the removal of thick outer layers the interface becomes indeterminate. A third approach is to dissolve one solid leaving the other intact, but again limitations are encountered. For example, only one side of the interface can be studied and the real boundary may be perturbed or damaged by the dissolving medium. Here we describe a new approach which may be used to study both the metal and oxide side of metal–oxide interfaces. Although this may at first appear to be a rather specialized application, the principles involved may be readily transferred to a number of other systems.

Metal–oxide interfaces may be studied in several ways. For interfaces formed between a relatively thin layer and a bulk material, layers of the thinner entity can be removed by ion sputter-etching the surface. If analysis of the freshly exposed surface is performed simultaneously using Auger electron spectroscopy[1], the surface composition as a function of depth into the specimen may be obtained. This 'depth profiling' capability permits the analysis of a material in three dimensions. When a particular sub-surface feature, such as an interface, is of interest, etching can be stopped when this is reached and a more detailed analysis performed.

A novel technique has been developed by Coad, Tappin and Rivière[2] for stripping oxide layers from metals to expose the interface on both the oxide and metal side. Previously one of the few reliable methods for the removal of an oxide from ferrous materials involved the dissolution of the metal by iodine–methanol solutions. Originally developed by Vernon, Wormwell and Nurse[3], this method has been extended more recently to iron–silicon alloys by Moseley, Tappin and Rivière[4]. Although a profile into the oxide could be obtained, the results suffered from the limitation that contamination of the oxide occurred during the process of dissolution. Coad's method, known as sputter ion plating is not subject to this disadvantage because the oxide is simply pulled away from the metal matrix.

The technique involves the deposition of a layer of nickel, or other suitable metal, onto the oxide surface at the elevated temperature of 300 °C. During the deposition process the oxide surface is subjected to bombardment with 1 kV argon ions at a pressure of 30 torr to encourage a strong nickel–oxide bond and the temperature regulated to prevent modification of the oxide film composition. On cooling to room temperature, stresses are induced between the oxide and its nickel overlayer sufficient to pull the oxide away from its base when the coating is deformed. Experiments using sputter ion plating have been carried out on iron–silicon alloys[2] and in our own laboratory on 20% Cr, 25% Ni, Nb stabilized steel[5].

The current UK civil advanced gas-cooled nuclear reactor uses a thin-walled 20% Cr, 25% Ni, Nb stabilized austenitic steel cladding for the fuel pins. For heat transfer purposes the surface of the steel tubing is roughened by circumferential ribs of 0.31 mm^2 section with a pitch of approximately 2.5 mm. Here we report the examination of two samples of this austenitic alloy (total composition 20% Cr, 25% Ni, 0.6% Nb, 0.6% Si, 0.05% C, balance Fe) which had previously been exposed to a CO_2, 1% CO gas mixture at 40 atm for 4,000 h at 550 °C and 650 °C respectively. An oxide layer of thickness between 0.5 and 2.0 μm was formed at the surface. To study the mode of formation and integrity of the oxide, each sample was coated with a 30-μm layer of nickel metal and oxide–metal partition was induced by bending the oxidized cladding alloy parallel to a surface rib. Since separation of the oxide and metal occurred in air, the metal side was contaminated with an air-formed oxide film. However, sputtering experiments using a beam of argon ions of energy 4 keV showed this film to be no more than a few

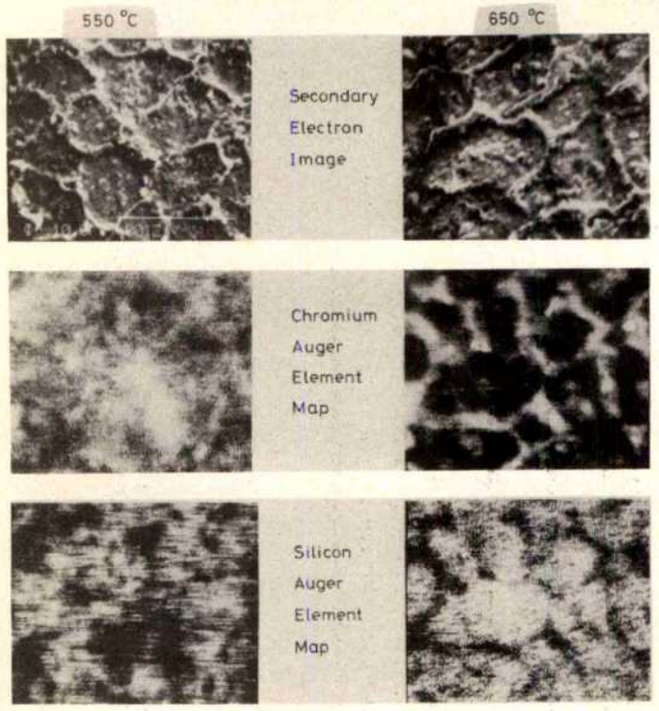

Fig. 2 Scanning electron micrograph and Auger element maps from the oxide side of the metal–oxide interface exposed by sputter ion plating a 20% Cr, 25% Ni, Nb stabilized austenitic steel.

atom layers in thickness and supported the view that separation had occurred at the metal–oxide interface rather than within the oxide.

The alloy side of the oxide–metal interface is illustrated in Fig. 1. It is this surface which cannot be examined readily by other methods. The secondary electron images from the 550 °C and 650 °C samples are very similar. Both show grains of ~20 μm diameter within the polycrystalline alloy which are clearly delineated by grooves at the boundary positions. The grooves corresponded to ridges on the oxide side of the interface which were pulled out from the grain boundaries during the process of separation.

Auger electrons emitted by a given element were measured over the area examined in the secondary electron micrograph to provide a visual display of the lateral distribution of the element in question. Maps of this type obtained using the technique of scanning Auger microscopy are illustrated for the elements nickel and chromium beneath the corresponding secondary electron image. Although not illustrated here, results of this kind were also recorded for silicon and iron. As Fig. 1 indicates, striking differences in the distribution of elements were observed from the two samples. At 550 °C an enrichment of nickel at some grain surfaces was noted, together with rather low concentrations at others but, following exposure at 650 °C, a consistently uniform concentration of this element occurred at grain centres with a corresponding depletion at the boundaries of the grains. Similarly, chromium appeared to be randomly distributed across the surface of the metal oxidized at 550 °C but at the higher temperature a significant enrichment was observed in the grain boundary regions. Maps for silicon and iron identified a similar pattern of behaviour, the higher temperature sample revealing the enrichment of silicon at grain boundaries and iron at grain centres.

Scanning electron micrographs of the oxide side of the interface are shown in Fig. 2, together with the Auger element maps from chromium and silicon. Iron and nickel were rarely detected on the oxide surface, an indication that the deposited nickel layer had not penetrated the oxide to the interfacial region. Detailed studies identified a marked difference in the composition of grain surface and grain boundary regions on this side of the oxide–metal interface. In contrast to the metal, the freshly exposed oxide counterpart of the 650 °C sample showed high levels of silicon at the grain centre and high chromium levels at the grain boundary positions but similar behaviour was not evident in the sample oxidized at 550 °C. Complementary information of this kind can be used to determine the mode of metal–oxide fracture. Results from the experiments at 650 °C, taken together with those from experiments at 850 °C (ref. 6) and argon ion etching, indicated that above the grains at the surface of the metallic structure, separation occurred between the metal crystallites and a very thin layer, ~70 Å across, of silicon-rich oxide. At the crystallite boundary regions within the surface of the polycrystalline metal on the other hand, oxide was formed as a wedge down the grain boundary and into the metal so that fracture occurred across the surface and through the bulk of the keyed oxide. Hence the Auger map from the surface, exposed when the oxide was torn away, revealed the presence of chromium, a major constituent of the bulk oxide, in the grain boundary regions.

At 550 °C simple metal–oxide separation no longer occurred. The intervening silicon-rich oxide was incompletely developed across the interfacial region and the metal and oxide were more strongly bound. In fact, the oxide film was so adherent that in certain areas of the surface, separation was only achieved by removing a portion of the metal substrate with the oxide layer.

Providing separation can be achieved, the sputter ion plating technique thus permits the examination of both the metal and oxide sides of a metal-oxide interface by scanning Auger electron spectroscopy. The data so obtained may be used to determine both the mode of separation and the strength of the metal–oxide interaction.

Last interglacial reef growth beneath modern reefs in the southern Great Barrier Reef

John F. Marshall & Peter J. Davies

Bureau of Mineral Resources, Geology and Geophysics, Canberra City, ACT 2601, Australia

Studies of modern coral reefs have shown that Holocene reef growth is relatively thin, and that in many instances it has developed on an older limestone surface[1–4]. This surface is commonly associated with leaching and pedogenic processes, indicative of subaerial exposure, and has been termed the solution unconformity[5]. Investigations into reef growth history have interpreted the pre-Holocene substrate as an older reef surface[2–4,6–8] that may or may not have undergone karst erosion during periods of lower sea level[6,9]. Uranium-series dating of corals directly below the uppermost solution unconformity at Eniwetok[10] and Mururoa[11] has shown that previous reef growth, before the Holocene, occurred ~120 kyr ago. We present here $^{230}Th/^{234}U$ dates that confirm a last interglacial age for reefal limestones directly beneath the uppermost solution unconformity in the southern Great Barrier Reef.

Previous drilling on the Great Barrier Reef has encountered the topmost solution unconformity at depths ranging from 4 to 22 m below sea level[2–4]. Radiocarbon dating of material below the unconformity has produced ages that are beyond the detection limit of this method, and there has been insufficient suitable

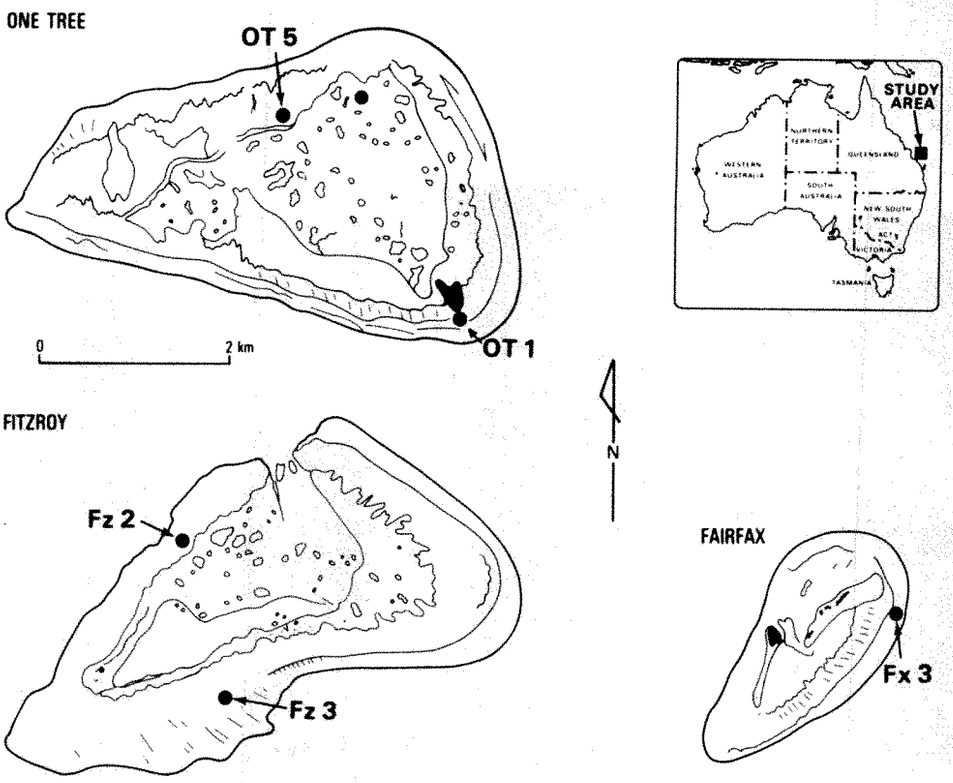

Fig. 1 Locality diagram and physiographic outline of the reefs showing the position of drill holes which penetrated below the solution unconformity.

material to enable absolute age determinations using the uranium-series technique[3]. Since then, shallow drilling operations in the southern Great Barrier Reef have penetrated the solution unconformity at depths ranging from 7.4 to 14.3 m on three reefs (Figs 1 and 2). Previously, seismic refraction profiling on these reefs indicated the solution unconformity at depths ranging from 8 to 23 m (ref. 12). Radiocarbon dating of corals above the unconformity have confirmed that it is Holocene[13–15], whereas below it, unrecrystallized corals produced radiocarbon ages in excess of 30,000 yr BP (ref. 14). Core material below the unconformity is commonly leached and cemented by low-Mg calcite, while in some cores the limestone is impregnated with soil humates or contains cross-cutting stringers of brown calcrete containing numerous rhizocretions. However, while the material below the unconformity shows the effects of subaerial vadose diagenesis, aragonite corals suitable for dating were found in five of the drill holes (Fig. 2).

The results of $^{230}Th/^{234}U$ dating of these corals are shown in Table 1. All the corals obey the closed system criteria, and their uranium contents and $^{234}U/^{238}U$ ratios fall within the expected ranges.

Two anomalous ages of 107 kyr from Fairfax Reef (hole 3) and 172 kyr from Fitzroy Reef (hole 2) are considered to have resulted from these corals not being in their original growth position. The 107-kyr coral from Fairfax Reef occurs directly on top of a pronounced soil horizon that represents the surface of the solution unconformity. Previously, this coral had produced a minimum ^{14}C age of 30,000 yr BP. Its presence above the unconformity suggests that it is not *in situ*. The 172-kyr age from Fitzroy Reef (hole 2) is more difficult to explain. In the absence of age determinations both above and below it, no reliance is placed on its accuracy.

Most corals occur in the age range of 122–145 kyr. This spread in the ages is consistent with results from previously dated last interglacial terraces[16–19] and the submerged foundations of atolls[10,11]. The two ages from One Tree Reef are older than those from Fairfax and Fitzroy Reef (hole 3). This could reflect variations in the timing of reef growth and their respective growth rates, such as seen in the modern reef. However, variations of this type in the Holocene reefs are only of the order of 2,000–4,000 yr, whereas the difference betweeen One Tree and the other reefs is >10,000 yr. Alternatively, it could reflect differing rates of subaerial erosion of the last interglacial reefs during the period of low sea level before the last transgression—a period of some 100,000 yr. The relatively greater depths to the solution unconformity in the One Tree Reef drillholes (Fig. 2) would seem to bear out this latter alternative.

On the assumption that sea level during the last interglacial was ~5 m higher than present, and that the reefs were capable of attaining this high sea level elevation, the present position of

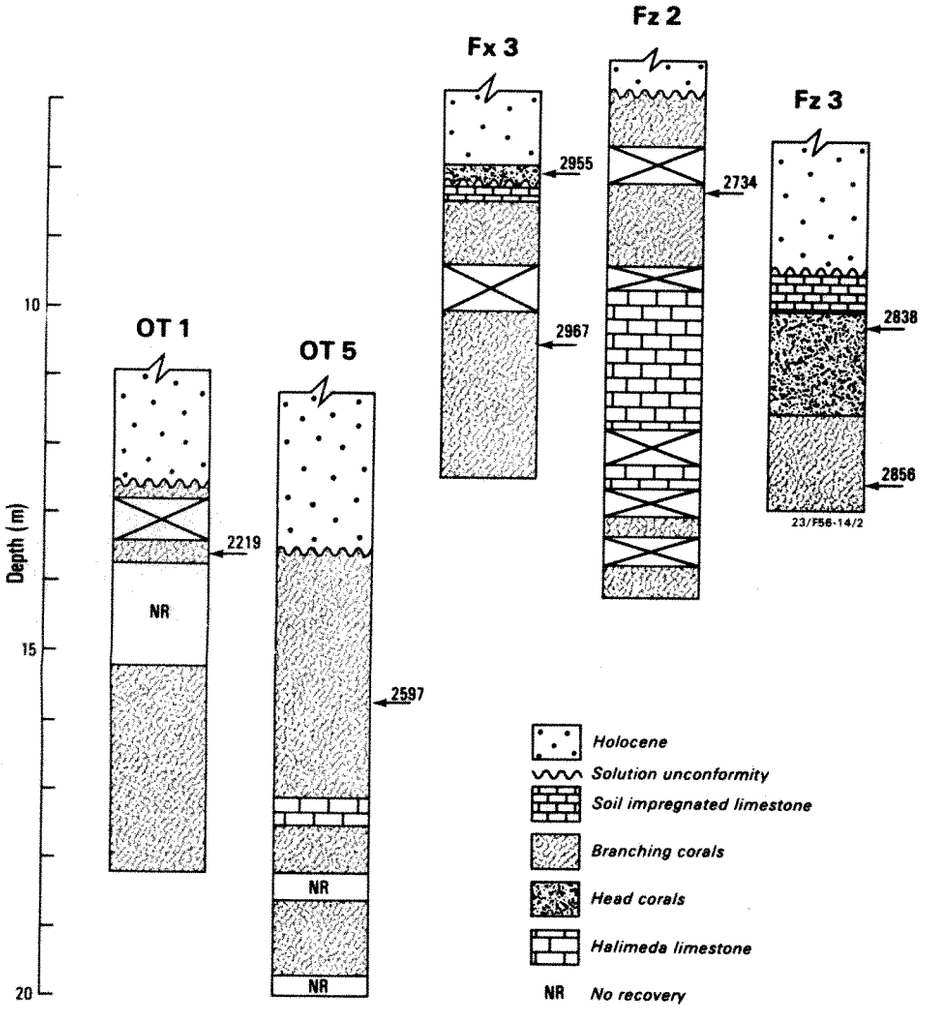

Fig. 2 Lithological logs of the pre-Holocene sections of the drill holes showing the position of the dated coral samples.

the solution unconformity in the drillholes suggests a lowering of the reef's surface of the order of 12–19 m during the intervening period between the last interglacial and the Holocene transgression. The position of last interglacial reefs and other strandline features removed from plate boundaries have verified that the sea level was higher than present by ~4–6 m (refs 19, 20). On the basis of present-day and Holocene growth rates it would have been possible for all the reefs dated here to have reached this high sea level position within the period of the last interglacial. For example, the 127-kyr date at ~11 m in hole 3 at Fairfax Reef (Table 1) indicates that for a uniform vertical accretion rate of 4 m kyr^{-1}, this section of the reef would have reached the position of the last interglacial high sea level by 123 kyr ago. Providing that the subsidence rate of the continental margin (0.05 m kyr^{-1}) has remained uniform[21], the present position of the unconformity would require a rate of erosion of the reefs' surface of the order of 0.07–0.14 mm yr^{-1}, a rate that is not unrealistic for subaerial weathering of reefal limestones[22]. Differential erosion between the perimeters of the reefs and their lagoons, possibly as a result of submarine lithification within the former, would accentuate the original relief in such a manner as to lend credence to the antecedent karst hypothesis[6].

The determination of the exact age and depth of the modern reef substrate has long been considered as crucial to understanding the development of coral reefs. The arguments regarding the age and nature of the substrate go back as far as Darwin's[23] and Daly's[24] theories on reef development, and continue to the present day. Before our results there were only two reefs (Eniwetok and Mururoa) where it had been shown that the foundations of extant Holocene reefs were last interglacial in age. Because these are both atolls, it is encouraging to find a similar age in a different tectonic setting, such as the shelf reefs of the Great Barrier Reef.

We thank G. O'Brien for the age determinations of the two corals from One Tree Reef and T. Torgersen for providing laboratory and counting facilities. H. H. Veeh kindly commented on the manuscript. Published with the permission of the director, Bureau of Mineral Resources.

Late Quaternary pollen records from Easter Island

J. R. Flenley & Sarah M. King

Department of Geography, The University, Hull HU6 7RX, UK

Easter Island is the most isolated piece of inhabited land in the world. It exhibited an unique megalithic culture[1–3], involving the sculpting of giant statues (moai) especially between AD ~1400 and ~1680[4] when, for unknown reasons, the culture suddenly collapsed. The island is also of interest in relation to Pleistocene climatic change as CLIMAP[5] predicted no reduction of sea-surface temperatures for this part of the Pacific at 18,000 yr BP. We have obtained fossil pollen records covering the past 37,000 yr from three craters on the island. They suggest that the late Pleistocene climate was cooler and/or drier than the present one. They also suggest the former existence of forest on the island, and its decline in the last millennium. This decline was probably due to deforestation by man and could have caused the cultural collapse.

The island (lat. 27°9′ S; long. 109°26′ W) appears to have been substantially without woody vegetation since its discovery in 1722[6–8]. The present vegetation is mostly grassland. The known native flora consists of 46 vascular species[9] of which only one, the endemic *Sophora toromiro* (Phil.) Skottsb., is a tree. This species is now extinct on the island, but survives in botanical gardens[10]. The only native shrubs are *Lycium carolinianum* Walt. and *Caesalpinia bonduc* (L.) Roxb. The chief herbaceous families represented are the Gramineae and Cyperaceae.

Initial work on the Quaternary palynology of Easter Island, without dating, was carried out by Selling[4] who showed that a woody vegetation had formerly occurred. He found pollen of a palm, which he believed might be *Pritchardia* sp., now extinct on the island.

In the present study, the deposits of three volcanic craters were cored, and single complete cores returned to the laboratory. All three craters hold freshwater, and the deposits are highly organic. The stratigraphy has been described elsewhere[11], and appears to be relatively simple. ^{14}C and ^{210}Pb dating were carried out on samples from the pollen cores. Figures 1–3 outline pollen diagrams; full results will be published later.

Oceanic islands are well known as recipients of pollen from distant sources[12]. In the present work some sparsely represented taxa, such as *Ephedra* and *Casuarina*, are thought to have arrived in this way, but the major pollen contributors, discussed here, are presumed to have grown on the island.

The dating results require comment. The Rano Raraku ^{14}C dates (Fig. 1) are augmented by assay for ^{210}Pb of 33 samples from the top 70 cm. The results suggest a mean accumulation

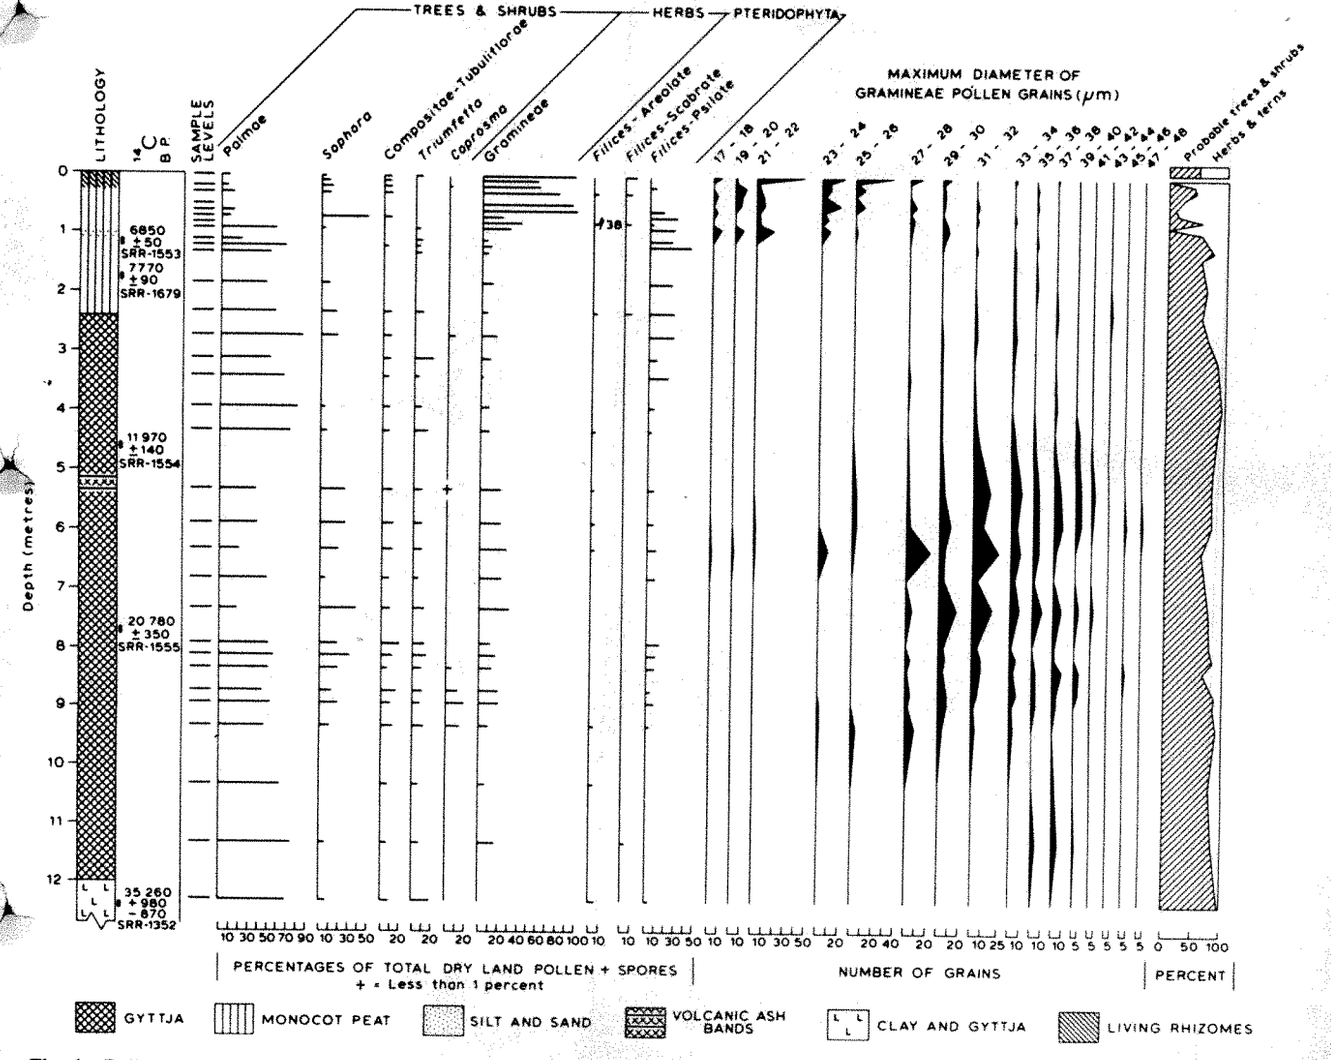

Fig. 1 Pollen diagram from Rano Raraku, alt. ~75 m. Only selected taxa are shown. Unidentifiable and unidentified grains only once represented more than 5% of the total. The summary diagram at right shows percentages of total dry land pollen and spores, not just of the taxa illustrated.

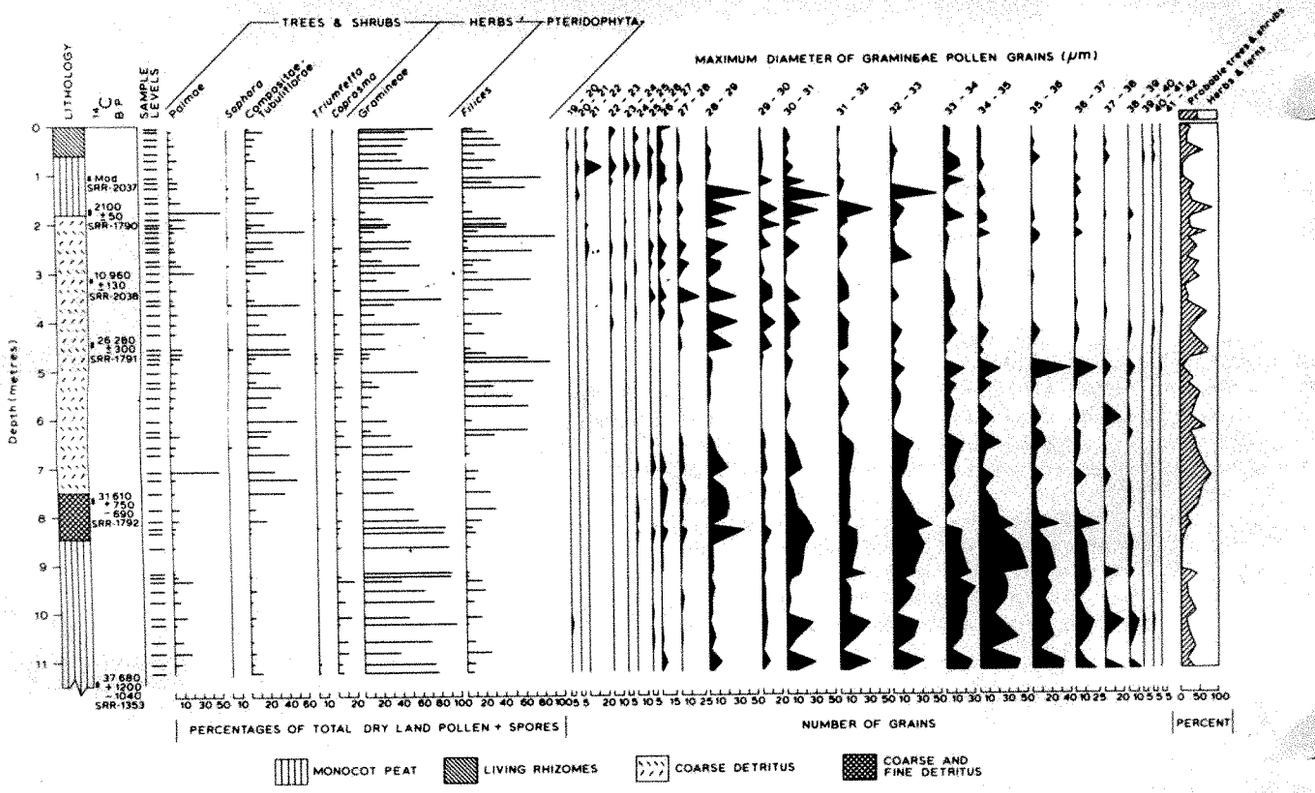

Fig. 2 Pollen diagram from Rano Aroi, alt. ~425 m. Only selected taxa are shown. Unidentifiable and unidentified grains never represented more than 2% of the total. The summary diagram at right shows percentages of total dry land pollen and spores, not just of the taxa illustrated.

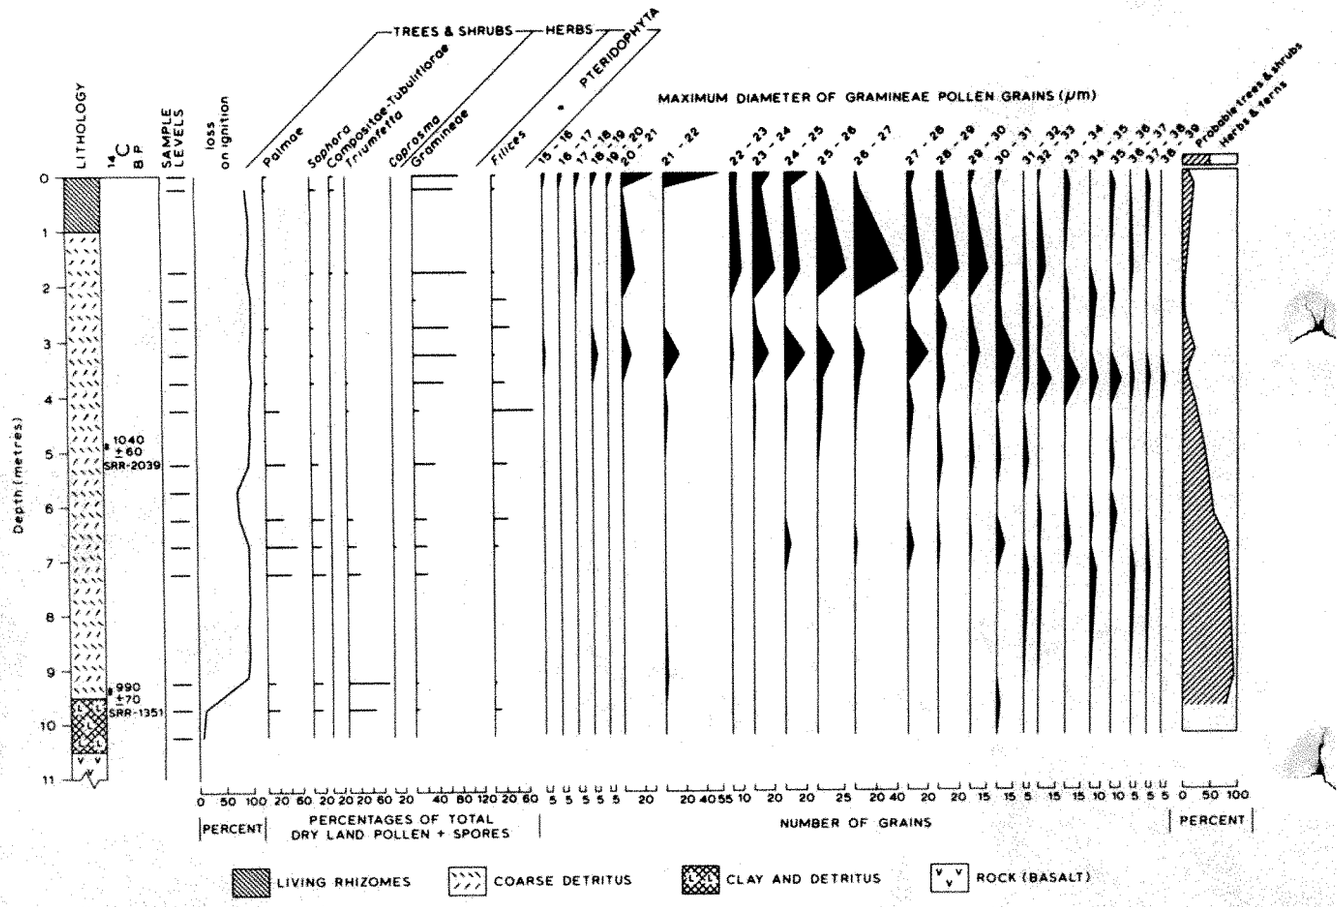

Fig. 3 Pollen diagram from Rano Kao, alt. ~110 m. Only selected taxa are shown. Note the changes of scale. Unidentifiable and unidentified grains were never more than 5% of the total. The summary diagram at right shows percentages of total dry land pollen and spores, not just of the taxa illustrated.

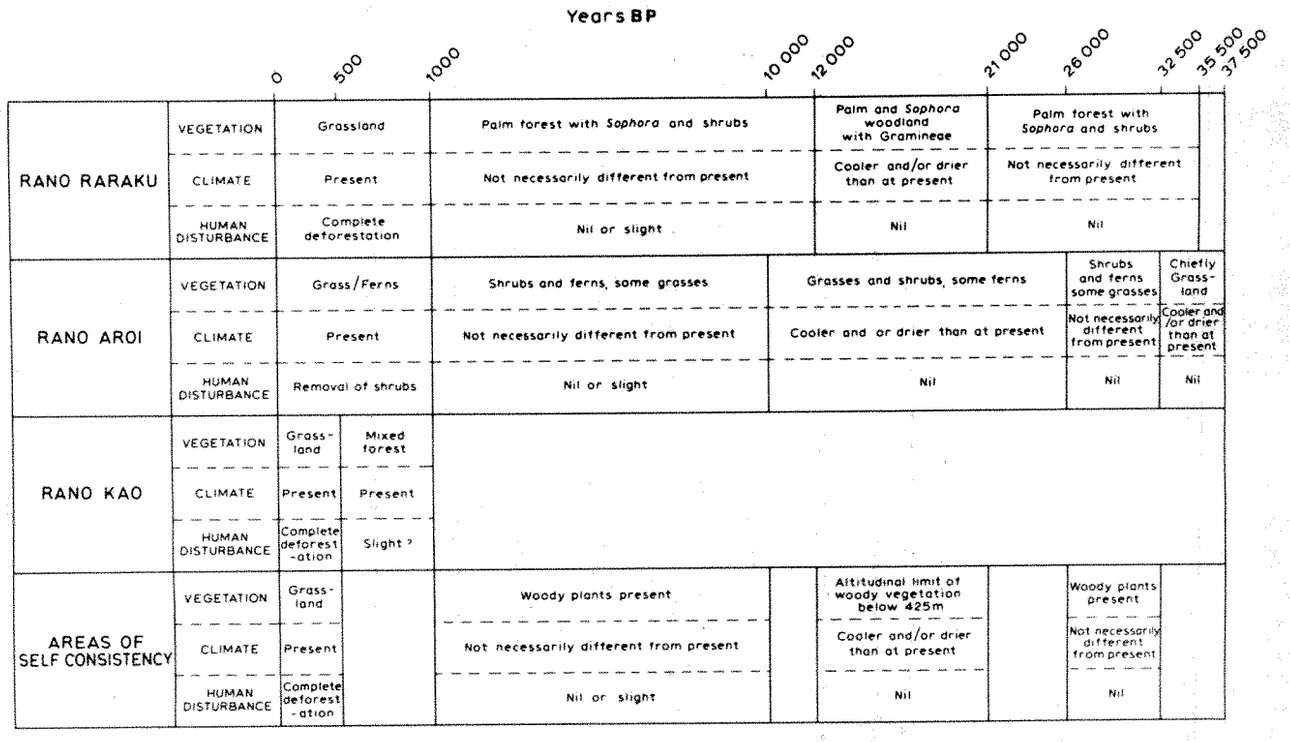

Fig. 4 Tentative conclusions as to former vegetation, climate and human disturbance on Easter Island. The time scale is given as a square root transformation.

rate of ~1 cm yr^{-1} for this part of the deposit. A date of 70 BP for 70-cm depth accords with the lower three dates in the core if a steady rate of accumulation is assumed below 70 cm, but this suggests that SRR-1553 and SRR-1679 are too old. This is feasible because they are close to the layer of inwashed silt and sand at 1.10 m. This probably indicates the inwash of soil carbon, a well known cause of contamination in radiocarbon dating[13]. The linear accumulation rate is therefore preferred for dating purposes. At Rano Kao (Fig. 3), similar contamination is suggested by the drop in loss-on-ignition values at ~6-m depth, and SRR-2039 is consequently rejected. At Rano Aroi (Fig. 2) there seem to have been changes in the rate of deposition. SRR-1790 is stratigraphically close to inwashed material seen in another borehole, and it could therefore be too old.

Figures 1–3 show evidence of the occurrence on the island of taxa which are now extinct there. The palm pollen found by Selling is abundant at all three sites. *Pritchardia*, which occurs on many Polynesian islands[14], has very similar pollen[15], but other possibilities cannot be excluded on pollen morphological grounds. This pollen taxon has been included in 'probable trees and shrubs'. There is also abundant pollen of Compositae, subfamily Tubuliflorae. Pollen morphology places this taxon in the tribe Heliantheae[16]. Plant geographical considerations make the most likely taxa *Chrysogonum* and *Campylotheca*[14–17], both of which comprise trees or shrubs. This pollen taxon has therefore also been included in 'probable trees and shrubs'.

The pollen records do not include all the taxa believed to be native today. Note that the two shrubs, *C. bonduc* and *L. carolinianum* are absent, but as they are both entomophilous, their absence is not particularly surprising. A total of 40 pollen taxa were recorded.

It is theoretically possible that some of the changes seen in the pollen record might be related to changes of facies in the stratigraphy. Thus at Rano Aroi the abundance of Tubuliflorae coincides with the occurrence of coarse detritus. The deposit contains no macroscopic remains of Tubuliflorae, however, which might have been expected if Tubuliflorae had been growing on the swamp. At Rano Raraku the rise of Palmae coincides with the occurrence of two 1-cm thick bands of volcanic ash at ~5-m depth, but it seems unlikely that so minor a volcanic event could have caused a vegetational change lasting several thousand years. The effect of such facies changes is therefore discounted.

For conciseness the vegetational and climatic interpretations will be considered simultaneously. To do this it is necessary to consider now the climatic significance of the major pollen taxa. *Sophora* grew on the island until recently, when it was probably destroyed by felling and grazing, and it may be taken as suggesting a climate similar to the present one. Palmae and Tubuliflorae were also present until recently (according to the pollen record), but Palmae were more abundant at Rano Raraku (~75-m altitude) and Tubuliflorae at Rano Aroi (~425-m altitude). This suggests that Palmae are indicative of warmer temperatures and Tubuliflorae of cooler temperatures, within the range found on the island today.

The Gramineae pollen of the record falls into two main categories. Grains below ~27 μm maximum diameter dominate the recent part of the record and are believed to be chiefly those of the grasses, both introduced and native, which now dominate most parts of the island. Grains above this size occur chiefly in the earlier part of the record and are thought to represent other native grass species which were more frequent before disturbance. They are particularly abundant in the Rano Aroi record and are probably therefore to be associated with the lower temperatures within the range found on the island.

It is certainly possible that both Gramineae and Palmae would have been favoured by drier conditions on the island in the past, as judged by the known ecological preferences of these families, but we have as yet no information on this point in relation to Easter Island taxa.

Bearing all these considerations in mind and interpolating where necessary between dates, it is possible to draw the tentative conclusions as to former vegetation, climate and human disturbance shown in Fig. 4. These will have to be revised as further dates and pollen and chemical analyses become available. Already, however, there emerges a fairly coherent picture. The chief conclusions are: (1) the island was probably formerly forested; (2) deforestation occurred, probably over a

considerable time span, but since 990 ± 70 yr BP at Rano Kao; (3) the climate was cooler and/or drier than at present during the period ~21,000–12,000 yr BP.

The chief interest arising from conclusion (3) is the general correlation in time and direction with late Pleistocene climatic changes elsewhere in both hemispheres, and the possible contrast with CLIMAP conclusions[5]. It is hoped that further work will clarify and quantify the climatic shift involved. Conclusions (1) and (2) are of archaeological interest, and do not conflict with the hypothesis[18] that the decline of the megalithic culture was associated with total deforestation. The latter could have been effective through shortage of food resulting from non-availability of fertile forest soils. Alternatively, or additionally, large timbers may have been essential for the moving of the moai[18,19] and deforestation could, therefore, have made it pointless to continue to carve them.

We thank Dr D. D. Harkness of the Scottish Universities Research and Reactor Centre for the ^{14}C assays, Mr J. D. Eakins of the Atomic Energy Research Establishment, Harwell, for the ^{210}Pb assays, Mrs M. Martin for the pollen preparations, and Mr K. Scurr for drawing of the figures. This work was financed by NERC research grant GR3/3316.

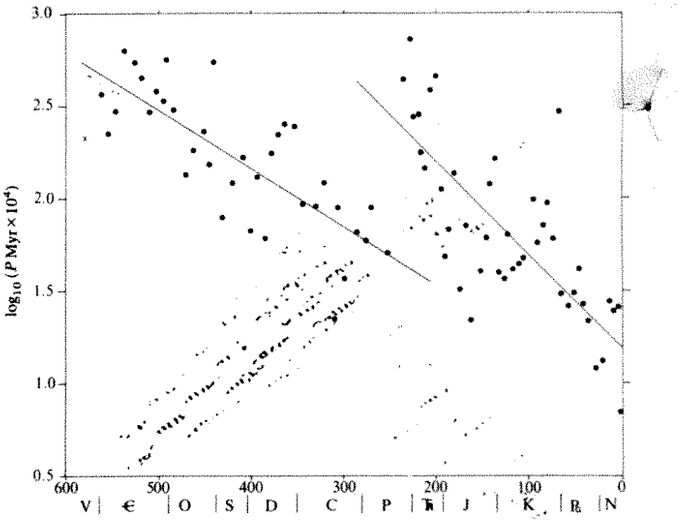

Fig. 1 Probabilities of extinction per Myr (P_{Myr}) through geological time, on a semilogarithmic scale. The abscissa is scaled in Myr BC and by standard symbols for geological periods (Table 1). The plotted regressions exclude the Vendian, because the datum plotted (×) includes soft-bodied forms, and the Maestrichtian, because of its uniquely divergent position. For the left regression, through the Leonardian, $y = -0.00313x + 0.904$, $r = 0.775$, $s_{yx} = 0.235$. For the right regression, from the Guadalupian, $y = -0.00502x + 1.191$, $r = 0.800$, $s_{yx} = 0.275$. (If the Maestrichtian is included, $y = -0.00478x + 1.240$, $r = 0.749$, $s_{yx} = 0.308$.)

A resetting of Phanerozoic community evolution

Leigh M. Van Valen

Biology Department (Whitman), University of Chicago, 915 East 57th Street, Chicago, Illinois 60637, USA

The early part of an adaptive radiation is thought[1] to show more taxonomic turnover than later stages. I show here that the effect on probability of extinction is one of exponential decrease, and that in the case of marine families this regular decline was interrupted by the great Permian extinction. A new exponential decrease followed, at a somewhat faster rate. The Cretaceous–Palaeogene extinction is the only other one detectably different from the scatter, and it had no apparent effect on extinction in the Cenozoic. These regularities support an interactive view of large-scale community evolution but do not uniquely determine the nature of the interaction.

Sepkoski[2] has critically compiled the known geological ranges, by stage whenever possible, of all marine families of invertebrates and vertebrates. I used his summary for the families which are readily preservable in the fossil record.

My analysis is based on probability of extinction[3] rather than absolute numbers of extinctions, the more common procedure. These approaches give different results when the total numbers of taxa differ among the set of taxa in a comparison. An epistemic (or a subjective or propensity) interpretation of probability gives a meaning to the probabiiity of a single event like an extinction, unlike the standard frequentist interpretation of probability. Probability of extinction is appropriate both for single taxa and for communities or broader groups; the same number of extinctions has a smaller expected effect when more taxa are present, just as for the same number of deaths in differently sized populations of individuals.

Probability of extinction decreased rather regularly throughout the Palaeozoic (Fig. 1). However, the late Permian extinction was somewhat larger than even those of the Cambrian, and even in the early and middle Triassic the probability was still about that for the Ordovician. Thus a new decrease was initiated, which has continued to the present. All but two of the post-Palaeozoic probabilities lie above an extension of the Palaeozoic regression. The scatter is homogeneous above and below the regressions and between the two regressions, and normally distributed about the regressions, but the later regression is significantly ($P < 0.02$, $P < 0.05$ if Maestrichtian included) steeper than the earlier one.

Other than the late Permian extinction with respect to the Palaeozoic regression, only the Maestrichtian (late Cretaceous) extinction is more than two standard deviations above the appropriate regression. This does not mean that all other extinctions are causally homogeneous, but any heterogeneity cannot be detected from this sort of analysis (*contra* Raup and Sepkoski[4]). It is therefore not feasible to estimate frequencies of collisions with large meteoroids, as has been done[12].

Some aspects are better seen in Fig. 2. The high Cambrian probabilities were preceded by a rise, ostensibly from no extinction at all in the Vendian. (The probability including soft-bodied forms is artificially high because such forms are almost never found in the early Cambrian; its true value could even be zero also.) A clustering of high probabilities occurs in the early Cambrian, late Devonian, late Permian, late Triassic and late

Each probability was estimated as the number of extinctions (last appearances) in the stage, divided by the average number of taxa at risk. The latter was estimated as the number of taxa at the beginning of the interval, minus half the extinctions, plus half the originations (first appearances) in the interval. This assumes that extinctions and originations are evenly distributed in the interval, which is not always true and can be easily corrected for when so desired, but even when the assumption is untrue the method provides an average value for the whole stage. For the middle and late Vendian this procedure is inappropriate because of the rapidly increasing diversity with few extinctions likely within the period; I estimated the taxa at risk as the number of extinctions plus half the number of survivors and used half the duration of the period as the time at risk. Probability per stage is appropriate if extinctions are concentrated at the end of stages. Questionable records were ignored, and the data include vertebrates as well as invertebrates. Data with accuracy less a stage were divided equally among stages, a procedure which undoubtedly makes at least the Cretaceous–Palaeogene extinction seem somewhat less extreme than it really was. Standard errors of the probabilities cannot be determined but are certainly less than the standard deviations about the two regressions in Fig. 1. Pseudoextinctions are negligible; in fact, I can think of no real case of pseudoextinction in the fossil record at the family level, which would require the last surviving species of an earlier family to give rise to the next family.

Jurassic, with some suggestions of rising probabilities before most of these local maxima.

The 'Great Dying' at the end of the Cretaceous would be unusually low for the Cambrian, and the late Devonian extinction (including more than just the Frasnian, *contra* the usual view) would be ordinary for the Ordovician. Cambrian (biomere) extinctions as well as that of the Cretaceous were mostly concentrated at the ends of stages, so probabilities per stage rather than per time are a better measure (Table 1). Apart from the Maestrichtian, the three largest deviations from the regressions are below rather than above. If these and similar deviations are real rather than artefacts of inaccuracy of the data (including stage lengths), they deserve study for their own sake. What causes intervals of low extinction? Such an interval, like one of stasis, is a real datum.

Darwin[5] and many others have proposed that organisms increase their absolute fitnesses, the average increasing through geological time. However, this does not appear to explain the pattern of Fig. 1 because there are two declines in probability of extinction, not just one. The Permian extinction reset the clock of community evolution, and it resumed a little faster than before. Similarly, control by the physical environment does not explain the bipartite distribution.

A decrease in probability of extinction can also be explained by an increase in the ratio of positive to negative interactions among taxa. Most plausibly this would involve a decreasing overlap of the adaptive zones[6] of taxa through time, a pattern which has independent supporting evidence[1]. The steeper post-Palaeozoic slope supports this hypothesis because many families did survive into the Triassic and presumably retained the broader aspects of Palaeozoic community structure. Readjustment should then be more rapid than from the initial establishment of animal communities in the Vendian and Cambrian.

The constancy of overall community fitness which is central to the Red Queen hypothesis[3,7] predicts an approximate constancy in evolutionary rate[3,8]. That is seen here at the community level, because the ratio of probabilities of extinction among successive equal intervals fluctuates about a constant value. This

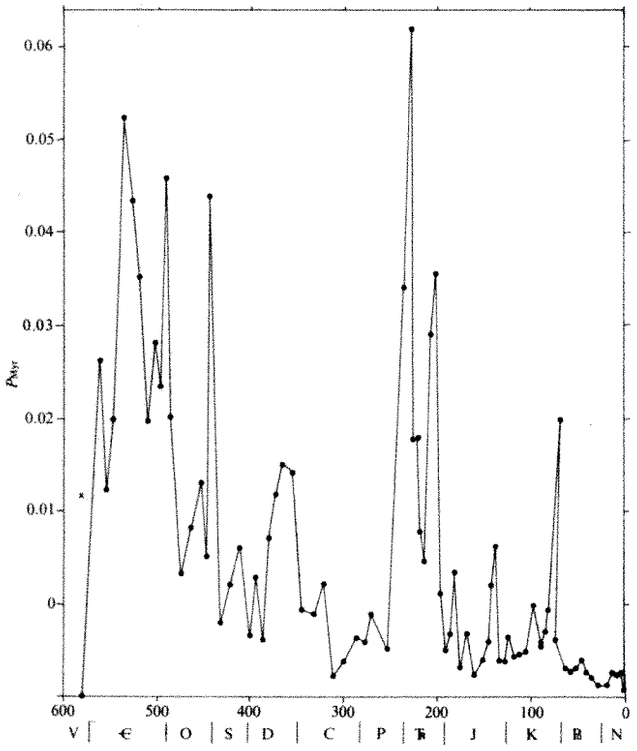

Fig. 2 Probabilities of extinction per Myr (P_{Myr}), as in Fig. 1, on an arithmetic scale. × is an artificially high value including soft-bodied forms. Abbreviations as in Table 1.

value is determined by the slopes of the regressions in Fig. 1; as it would differ numerically for intervals of different lengths, the value of an average ratio itself has little interest. However, in this way the exponential nature of the decline in probability can be explained in a natural way.

As a subsidiary point, all three radiations (angiosperms[9], placental mammals[10] and marine animals) for which data are available show unusually low probabilities of extinction, ostensibly zero in each case at the resolution possible, at the very beginning of the major radiation. Both predation[10] and competition were probably unusually low in each of these cases, although density-dependent regulation of population (or metapopulation) density more or less requires that some competition occur among taxa expanding into new adaptive zones[11]. Thus, initially it is perhaps easier to avoid competition by evolving a new adaptation than it is to stand and fight, evolving adaptations for competition. This should be testable experimentally for suitable organisms in a suitably complex environment.

A cladistic classification would preclude any analysis like that of the present paper.

I thank J. J. Sepkoski Jr for the summary of his data and for comments; A. Hoffman, J. A. Kitchell, and J. W. Valentine for comments; and V. C. Maiorana for help.

Air pollution increases *Aphis fabae* pest potential

G. P. Dohmen, S. McNeill & J. N. B. Bell

Department of Pure and Applied Biology, Imperial College, Silwood Park, Ascot, Berkshire SL5 7PY, UK

Many observations have been made of increased population densities of herbivorous insects in areas subject to air pollution[1–3]. However, in the absence of experimental investigations, the significance of most of these observations is not clear and any underlying causal mechanisms remain obscure. The only published studies designed to investigate experimentally the impact of pollutants on plant–herbivore systems involve fumigations with either hydrogen fluoride (HF)[4] or sulphur dioxide (SO_2)[5,6] of *Phaseolus vulgaris* and *Glycine max* plants, infested with the Mexican bean beetle, *Epilachna varivestis*: in general the results showed that HF reduced beetle performance whereas SO_2 stimulated it, but the relative importance of direct and indirect effects of the pollutants was not elucidated. We show here stimulatory effects of SO_2 and NO_2 and ambient London air on the growth of the black bean aphid, *Aphis fabae*, and demonstrate that these have been mediated entirely via the host plant.

Annual surveys of *A. fabae* abundance in south-east England have shown consistently higher levels of infestation on field beans, *Vicia faba*, in an area downwind of London and in the proximity of heavy industry, than predicted on the basis of the number of eggs recorded on the winter hosts (M. J. Way, personal communication). We hypothesized that this might be caused by air pollutants drifting into the area and established an experimental programme to investigate the phenomenon.

Fumigation experiments were conducted in a pair of 0.7 m^3 Perspex chambers, situated inside a heated glasshouse. The chambers were ventilated with four changes per minute of charcoal-filtered air, and SO_2 or NO_2 was added from a cylinder to give a controlled constant level of pollutant in one chamber. *A. fabae* was reared in culture in a constant temperature room and alatae were removed to clip cages attached to *V. faba* leaves. Two-day-old offspring were removed from the cages for use in each experiment. Subsequent performance of the nymphs was assessed by calculating either final fresh weight or mean relative growth rate (MRGR) on the basis of increases in fresh weight. For each pollutant, two types of experiment were carried out, designed to separate direct and indirect effects on the aphids, respectively. Effects mediated via the plants were investigated by fumigating three-leaf-stage seedlings with 200–500 $\mu g\ m^{-3}$ of SO_2 (mean 400 $\mu g\ m^{-3}$) or 400 $\mu g\ m^{-3}$ NO_2 for 7 days; the plants were then transferred to a controlled temperature room at 20 °C and one nymph was placed on top of each and its MRGR measured over the succeeding 3 days. The possibility that the pollutants had a direct effect on the insects was examined by carrying out 400 $\mu g\ m^{-3}$ fumigations with either pollutant while the insects were feeding on artificial diet sachets. At the end of the 3-day fumigation the mean fresh weight per aphid on each sachet was measured and compared between treatment and control.

Table 1 shows MRGR of the aphids grown on post-fumigation plants. Both SO_2 and NO_2 caused significant increases in aphid performance, with MRGR being stimulated by 6.5% and 8.4%, respectively. In contrast, direct fumigation of aphids feeding on the artificial diet produced no significant differences in growth (SO_2 treatment, 126 ± 4 μg; control, 118 ± 6 μg; NO_2 treatment, 90 ± 7 μg; control, 93 ± 5 μg). The MRGR of the diet-fed aphids was not measured directly, because of the problems of disturbance inherent in making repeated measurements on the same animals. However, by taking a mean value for the initial

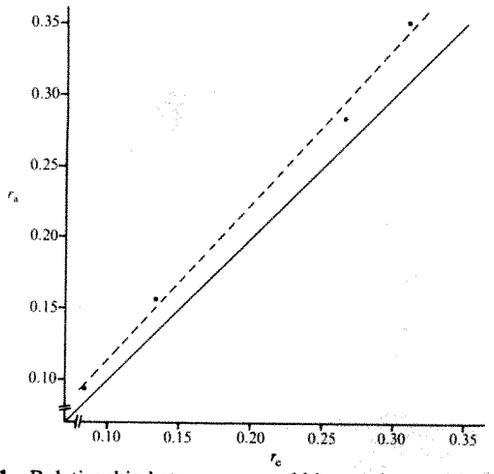

Fig. 1 Relationship between rates of biomass increase for *Aphis fabae* on *Vicia faba*, grown in either ambient London (r_a) or charcoal-filtered (r_c) air. Dashed line, $r_a = 1.086r_c + 0.006$; solid line, $r_a = r_c$.

weight of 2-day-old aphids, the MRGR of diet-fed animals was estimated and shown to be almost identical between the fumigation and control treatments, for both pollutants (Table 1). Although growth was slower overall on the artificial diet, as found by other workers[7], we consider that the difference is sufficiently small to provide a valid comparison between indirect and direct effects of the pollutants on the aphids.

The fumigations described here used SO_2 and NO_2 concentrations which are higher than the mean annual levels recorded currently in British cities. Therefore, to determine the effect of ambient urban air pollution on the performance of *A. fabae*, another pair of 0.7 m^3 chambers was set up on a roof at Imperial College in South Kensington, central London. These were ventilated with ambient air or the same air which had been passed through a charcoal filter, which removed at least 70% of SO_2 and 50% of NO_2 but no nitric oxide (NO) (S. M. Usher, personal communication). Pots containing three three-leaf-stage *V. faba* plants were infested with *A. fabae* by enclosing each pot in a gauze cage with nine adult alatae. The caged plants were then placed in the chambers, where they were grown for 9–12 days in four separate experiments between May and July 1983. The daily SO_2 concentrations measured at the nearest National Air Pollution survey site (500 m distant) ranged between 34 and 145 $\mu g\, m^{-3}$ during the experimental periods (S. T. Mossman, personal communication). No local measurements of nitrogen oxides are available, but on the basis of data from elsewhere in central London, the ratio of SO_2:NO_2 has been estimated[8] to be about 1:0.7, which would give concentrations of NO_2 at South Kensington of 20–100 $\mu g\, m^{-3}$. At the end of each experiment, the aphid offspring in each chamber were counted and weighed and the rate of biomass increase (r) was calculated ($B_t = B_0.e^{rt}$, where B_t = final biomass, B_0 = initial biomass and t = duration of the experiment in days). Different climatic conditions resulted in considerable variation in population growth between experiments, precluding direct comparisons of biomass. Figure 1 shows the relationship between the rates of biomass increase for the ambient air (r_a) and charcoal-filtered air (r_c) treatments. The regression line is significantly greater than a slope of 1 ($P < 0.01$), and there was a 12% increase in r_a over r_c throughout the series of experiments.

The results presented here provide strong evidence that two of the principal phytotoxic air pollutants occurring in the UK can enhance the performance of a serious agricultural pest. Such seemingly small increases in productivity of the insect can, because of the logarithmic nature of population growth, result in large increases in pest populations over small time periods. They will also tend to lead to more frequent escape from control by natural enemies[9]. The fumigation experiments demonstrate that these effects on aphid performance are indirect and mediated via changes in the plant. We have carried out a preliminary investigation on the nature of these changes by analysing the amino acid spectrum of *V. faba* plants subjected to the 7-day SO_2 fumigation treatments used in the present work. Consistent changes, both negative and positive, were detected for several key amino acids. It is well established that the amino acid composition of a plant has the potential to influence insect performance[10,11]. However, the significance of the observed changes for *A. fabae* growth is uncertain and will be the subject of future research.

Table 1 Mean relative growth rate over 3 days of *Aphis fabae* subjected to SO_2 or NO_2, either directly on artificial diet or indirectly via prefumigated plants

		Pollutant	Control	Significance
SO_2	Plant*	0.540	0.507	$P < 0.01$
	Artificial diet†	0.395	0.394	NS
NO_2	Plant‡	0.575	0.530	$P < 0.01$
	Artificial diet§	0.369	0.370	NS

Mean relative growth rate ($\mu g\, \mu g^{-1}\, d^{-1}$) = (ln(final weight) − ln(initial weight))/no. of days growth. NS, not significant.

* Mean of 5 experiments with 15 replicates per treatment.

† Mean of 2 experiments with 15 replicate sachets per treatment, each with a mean of 10 aphids.

‡ Mean of 4 experiments with 15 replicates per treatment.

§ One experiment with 15 replicate sachets per treatment, each with a mean of 10 aphids.

We consider that the results described here indicate a strong possibility that air pollution has a serious economic impact on crop productivity, as a result of increased pest incidence, as well as exerting the more generally recognized direct phytotoxic effects. It is necessary for such work to be extended to a much wider range of pest types and host species to assess the overall importance of air pollution/insect/crop interactions in the field.

We acknowledge the support of the Commission for the European Communities Environment Programme in providing G.P.D. with a studentship, and thank Mr I. H. M. Fosbrooke, Dr D. J. Galley and Mr M. E. Cammell for advice and the provision of technical facilities.

Direct transfer of carbon between plants connected by vesicular–arbuscular mycorrhizal mycelium

R. Francis & D. J. Read

Department of Botany, University of Sheffield, Sheffield S10 2TN, UK

Mycorrhizal infection of plants in many natural vegetation systems arises when uninfected roots make contact with mycelia spreading from infected roots[1,2]. The result of the infection is that connections are present between the roots of individual plants. It has been shown by autoradiography that these interconnections provide a direct pathway for the transfer of carbon between ecto-mycorrhizal plants[2,3]. Inter-plant transfer of carbon[4] and phosphorus[5–7] has been reported in plants with vesicular–arbuscular (VA) mycorrhizas, but in the absence of

comparable evidence it remains a possibility that in these cases the pathway is indirect, uptake by the fungus of the 'receiver' plant occurring only after leakage of the nutrients from roots of the 'donor'. We now show using autoradiography that transfer of carbon between plants connected by VA mycorrhizal mycelium occurs primarily by the direct hyphal pathway. It is further shown that the magnitude of the transfer is strongly influenced by shading of 'receiver' plants indicating that movement is governed by source–sink relationships.

Seedlings of *Plantago lanceolata* were used as 'donors' both of infection and of labelled carbon. They were first grown in either the non-mycorrhizal (NM) or mycorrhizal (M) condition in trays of dune sand partially sterilized (PS) by irradiation. Two categories of M plants were produced, one by inoculation with field collected root pieces (unspecific inoculum) and the other with surface-sterilized spores of *Glomus caledonium* (specific inoculum). After 5 weeks both the M and NM donor plants were transferred to fresh PS sand in transparent plastic Petri dishes, to which also were added three aseptically grown seedlings of *Festuca ovina*. Twelve dishes of each category of donor (NM, M field inoculum, M specific inoculum) were established. Inspection of *Festuca* roots in randomly selected dishes after 6 weeks revealed infection levels of 30–50% in M non-specific and 15–20% in M specific inoculum categories. The sand surface was then coated with warm molten paraffin wax, to ensure a seal around the bases of all plants and around the dish circumference. Immediately before application of isotope to donor plants, the receiver plants in six dishes of the NM and six of the field inoculum categories were subjected to shade treatments. Darkness was obtained by loosely covering *Festuca* shoots with aluminium foil, half-shade by covering the shoots with muslin cloth, the remaining dishes being exposed to full illumination. Shoots of donor plants were then sealed in transparent plastic boxes into each of which 30 μCi of $^{14}CO_2$ was released. The plants were exposed to the isotope for 2 days after which time the shoots were excised, and the root systems in three dishes of each of the three categories of plants were prepared for autoradiography by gently removing sand under a fine jet of water. Roots, and in the case of M plants, their mycelial interconnections were then photographed through the transparent dish base before autoradiographic stripping film was applied to the roots which were exposed to the film for 2 days. The remaining M field inoculum and NM plants were harvested, ground in liquid nitrogen and digested in NCS tissue solubilizer before ^{14}C levels of their roots and shoots were determined quantitatively by liquid scintillation counting.

Roots of *Plantago* and *Festuca* can be readily distinguished on the basis of size (Figs 1*a*, 2*a*) and in the inoculated dishes a network of hyphae is seen to form frequent interspecific linkages between plants (Figs 2, 3). Autoradiographs reveal that whereas the roots of NM donor plants are strongly labelled no activity is detected in those of *Festuca* even where they are in

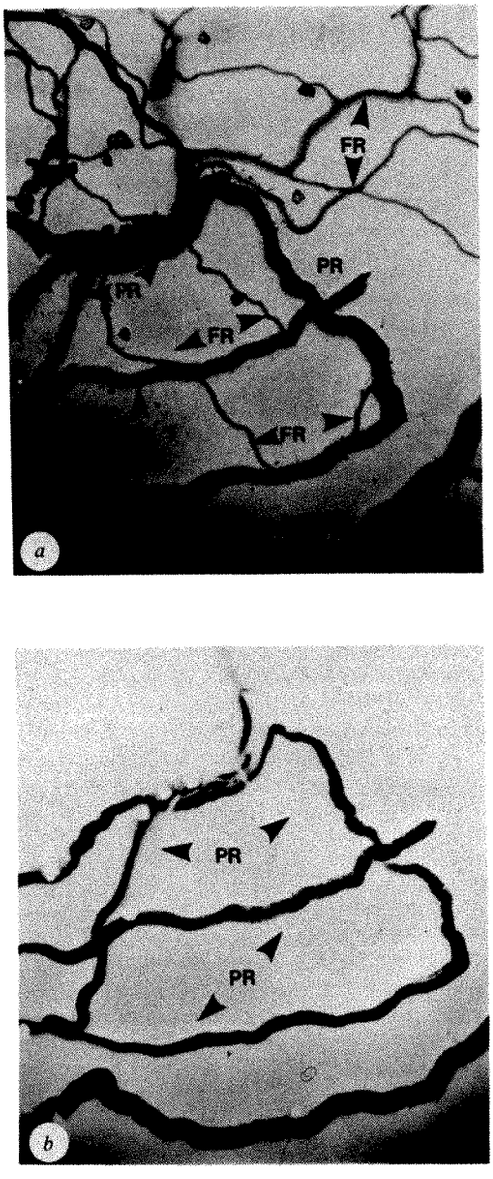

Fig. 1 *a*, Light micrograph of roots of an NM system after removal of sand showing closely intertwined roots of *Plantago* (PR) which are relatively robust, and *Festuca* (FR) (×15). *b*, Autoradiograph of same area as *a* showing accumulation of radioactivity in the donor, *Plantago* (PR), and complete absence of detectable transfer even into the most closely associated *Festuca* roots (×15).

Table 1 Radioactivity in shoots and roots of receiver plants (*Festuca ovina*) under three light regimes

Treatment	Receiver category: *Festuca* mycorrhizal			*Festuca* non-mycorrhizal		
	Activity in root (d.p.m. per mg dry wt)	Activity in shoot (d.p.m. per mg dry wt)	Activity in whole receiver plant as % of that in donor	Activity in root (d.p.m. per mg dry wt)	Activity in shoots (d.p.m. per mg dry wt)	Activity in whole receiver plant as % of that in donor
Full light	8,908* ± 3,530	363†‡ ± 242	0.015	656‡ ± 403	147‡ ± 194	0.0019
Half Light	18,072* ± 7,647	479†‡ ± 75	0.048	264‡ ± 365	229‡ ± 372	0.0010
Dark	57,218* ± 12,372	51‡ ± 38	0.112	171‡ ± 100	ND†	0.0005

Counts are expressed as d.p.m. mg dry weight (with 95% confidence limits) and as percentage of the total activity in the donor plants at harvest ($n = 6$). ND, no counts above background detected.

* Significant difference between this and all other values of activity at both treatment and category levels at $P < 0.05$.

† Significant difference between this and other value so marked at $P < 0.01$.

‡ Value not significantly different from other treatments in the same category.

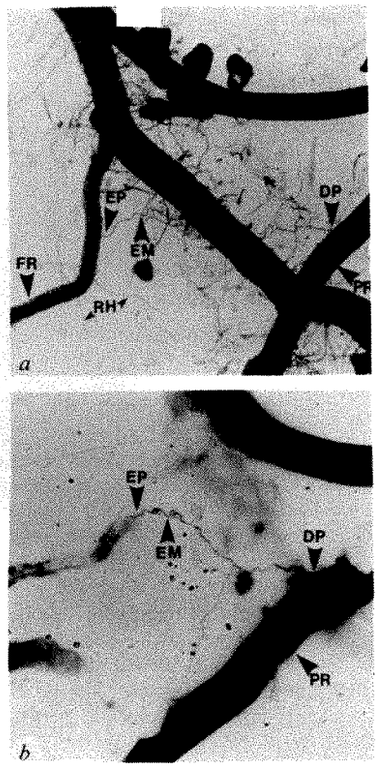

Fig. 2 *a*, Light micrograph of roots in a specific inoculum system showing *Plantago* 'donor' root (PR), *Festuca* 'receiver' root (FR) with many root hairs (RH), and interconnecting endophyte mycelium (EM) of *Glomus caledonium* (×40). *b*, Autoradiograph of same area as *a* showing heavy labelling of donor root (PR) and of endophyte mycelium (EM). Mycelial linkage can be seen from departure point (DP) on donor root to entry point (EP) on receiver root. Radioactivity in receiver roots is restricted to area of developing infection around the fungal entry point (EP) (×40).

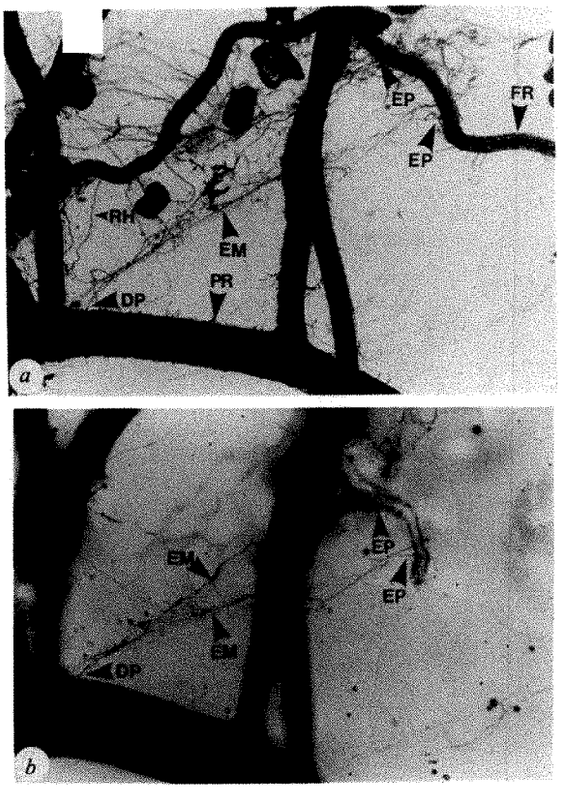

Fig. 3 *a*, Light micrograph of roots of a field inoculum system with typical fascicle of hyphae (EM) passing from departure point (DP) on 'donor' root (PR) and branching to form an entry point (EP) in the upper *Festuca* root (FR) (×40). *b*, Autoradiograph of same area as *a* showing accumulation of radioactivity in the hyphal fascicle (EM), at the entry point (EP) and in the infected part of the *Festuca* root (×40).

close physical contact with *Plantago* (Fig. 1*b*). Indeed, there is little evidence of loss of carbon through leakage from roots of either NM or M donor plants. In the M systems, however, label has moved from donor roots into the external mycelium and to connected receiver roots where it has accumulated around newly formed infections of the *G. caledonium* systems (Fig. 2*b*) and in the vesicles and arbuscules of the more advanced field inoculum infections (Fig. 4*b*). Labelling of mycelium is most pronounced in the coarse hyphae of *G. caledonium* (Fig. 2*b*). The finer hyphae of the field inoculum systems are often grouped together in fascicles running between roots. Chlamydospores developing on these hyphae become sinks for accumulation of label (Fig. 4*a*, *b*) confirming an earlier report[8], which was based upon counting methods. Again, only infected roots accumulate label (Fig. 4*b*) most of which can be shown by subsequent staining to be restricted to vesicles and arbuscules. This pattern of tracer movement indicates that in VA, as in ectomycorrhizas[2], transfer of carbon between plants occurs primarily by a direct hyphal pathway. Slow leakage may yield some assimilate to scavenging mycorrhizal hyphae and so provide an additional indirect or facilitated uptake by receiver plants but the significance of such a pathway is likely to be relatively small not only because leakage is restricted but because of intense competition for such materials amongst the microorganisms of the rhizosphere.

Quantitative analysis of radioactivity in the plants (Table 1) confirms the occurrence of assimilate transfer between mycorrhizal seedlings. While label is scarely detectable in NM plants, levels of activity in M receiver roots of both categories is high and in darkened M plants is six times greater than in those which are fully illuminated. Since the quantity of label moved is strongly influenced by shading it is likely that levels of transfer are largely governed by source–sink relationships. Relatively little activity is detected in shoots of either M or NM receiver plants, probably not only because of the evident capacity of the endophyte mycelium in the root to accumulate labelled material but also because the period of exposure to the isotope was short. Nevertheless the fact that levels of carbon in whole receiver plants can reach over 0.1% of those in donors, even in this limited time span, indicates that whole plants may be to some extent interdependent in terms of assimilate supply. The detection of isotope in the receiver does not, by itself, prove net movement of carbon to these plants, and longer term studies, now being carried out, are required to quantify further the assimilate transfer patterns.

Since seedlings frequently spend their early lives in adverse light environments these observations are likely to be of great ecological and physiological significance. It has been suggested previously[9–11] that the mycorrhizal fungus may form a vigorous sink for host assimilate in the individual infected plant, but in nature plants occur in communities in which individuals are interconnected at both intra- and interspecific levels, through their mycorrhizas. Our results indicate that carbon will move between these plants along gradients caused by differences of illumination and hence of sink strength. Early mycorrhizal infection would provide enhanced nutrient supply but could be critically disadvantageous in terms of the carbon drain imposed by the fungus. This study shows that seedling infection may be sustained by direct transfer of assimilates from neighbouring mature plants which are more likely to be fully illuminated and

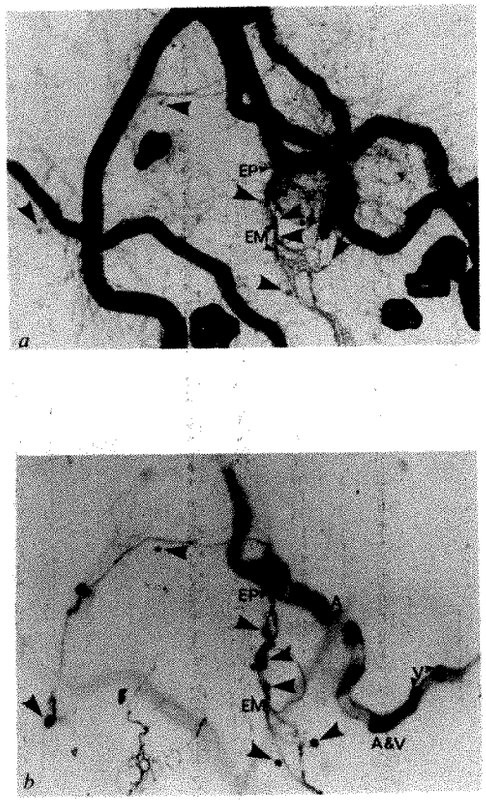

Fig. 4 *a*, Group of *Festuca* roots from field inoculum system showing infection point (EP) arising from a fascicle of hyphae (EM) in which numerous chlamydospores (arrowed) are developing (×40). *b*, Autoradiograph of this group showing accumulation of radioactivity at the entry point (EP), in vesicles (V) and arbuscules (A) along the infected root, in the mycelial fascicle (EM) and in the developing spores. Uninfected roots contain little or no labelled material (×40).

from which infection has spread. There is the further possibility that during the critical establishment phase the entire seedling may live for a period in partial heterotrophic dependence upon its neighbours. The extent of this dependence will be revealed in experiments now being conducted over a longer time period.

We thank Dr F. E. Sanders and Mr L. Reed for supplying spores of *G. caledonium*.

X-ray diffraction evidence that actin is a 100 Å filament

E. H. Egelman

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

R. Padrón

Laboratorio de Biofísica del Músculo, Centro de Biofísica y Bioquímica, Instituto Venezolano de Investigaciones Científicas, Caracas 1010A, Venezuela

The shape of the actin monomer has been determined by X-ray crystallography[1] and image analysis[2] to be a prolate ellipsoid consisting of two domains. A key structural question is how this monomer is assembled into the biologically important actin filament. Two completely different classes of models of F-actin have recently appeared. In one, the long axis of the monomer is oriented parallel to the filament axis[1,2], while in the other it is nearly perpendicular to that axis[3–5]. Fowler and Aebi[6] have argued that a proper assessment of the diameter of the actin filament can distinguish between the correctness of these models, since the 'perpendicular' model is about 95 Å in diameter, while the 'parallel' model is about 75 Å in diameter. Using electron microscopy, they have determined the diameter to be between 70 and 80 Å, consistent with their model. Egelman and DeRosier[3] also provided evidence from electron microscopy that the filament was about 95 Å, consistent with their perpendicular model. However, all specimens prepared for electron microscopy are susceptible to various artefacts induced by the preparation procedure. X-ray diffraction of specimens in solution allows one to examine objects in their native state. Data from X-ray diffraction of actin filaments in live muscle are presented here which show that a reasonable value for the diameter of F-actin is between 95 and 100 Å.

The strongest feature in the muscle X-ray pattern arising from the thin filament is the 59 Å layer line (the measured amplitude distribution is shown in Fig. 1*A*). Because of the different helical symmetries of actin and myosin in muscle, the 59 Å layer line arises only from the thin filament and is related to the distribution of density along the 59 Å left-handed one-start helix of the actin filament. Since the long-pitch strands of tropomyosin are nearly perpendicular to this short-pitch actin helix, tropomyosin will make almost no contribution at low resolution to the diffracted intensity along this layer line[7]. Therefore, by using the phases determined by electron microscopy of negatively stained filaments[3] one can use the X-ray amplitudes to generate a projection of the actin density along this 59 Å helix. Computed transforms of negatively stained filaments showed that the phase was relatively flat across the single broad amplitude peak (considerations of phase continuity show that this must be the case for an object the approximate diameter of F-actin). The resulting helical projection is presented in a one dimensional form in Fig. 1*B*. The X-ray data used were of limited resolution (extending out to 0.020 $Å^{-1}$ from the meridian), but it is clear that any higher resolution data (out to 0.030 $Å^{-1}$) are weak and therefore could not dramatically change the distribution. A comparable helical projection (using the same resolution cutoff) obtained from the model of Egelman and DeRosier is also shown.

The model data match the X-ray data well, the only difference being that the observed data extend out further in radius than the model. The X-ray data shown are consistent with a filament having significant mass extending out to a 100 Å diameter, and are completely inconsistent with a 70–80 Å diameter filament. A comparable plot to Fig. 1*B* (data not shown) has been made using the recently published layer line intensities from a relaxed smooth muscle[8]. The intensity distribution shown by Tajima *et*

EXAMINE ON FREE APPROVAL WITHOUT COMMITMENT

TWO NEW reliable, up-to-date and complete biotechnology information resources.

Detailed information on every aspect of biotechnology worldwide

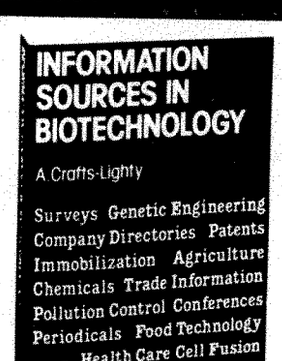
An indispensable guide to:
★ Products, services and research
★ Companies ★ Information sources.
★ Government and international agencies

THE INTERNATIONAL BIOTECHNOLOGY DIRECTORY 1984 —
- is thoroughly international
- features a unique BUYER'S GUIDE to products, research and services
- covers both the old and new biotechnologies

The Directory tells you:
★ Who your competition is, and what they are doing.
★ Who are potential customers and suppliers.
★ Where to buy equipment, chemicals and services.
★ Where culture collections are located and what cultures they hold.
★ Who imports/exports biotechnology products in over 20 countries.
★ Which government departments are associated with biotechnology.

All compiled by the eminent biotechnologist Dr. Jim Coombs and now available to you on **FREE APPROVAL.**

Macmillan Paperback 320pp **September 1983**
ISBN 0 333 36178 4 **£40.00/$80.00**



The ONLY guide to the selection of cost effective biotechnology information sources

★ covers both old and new technologies
★ covers technical and commercial literature
★ covers difficult and hard to trace sources
★ includes over 20 at-a-glance evaluation tables
★ provides an Index of publishers and their addresses

Dr. Crafts-Lighty, Head of Information and Library Services at Celltech Limited, systematically and critically reviews all the important information sources:

Summer Courses at the MBL

June 10–August 25, 1984

Biology of Parasitism John David, Harvard Medical School, Director

This unique program emphasizes the enormous potential utility of the parasitic protozoa and helminths as models for the study of the regulation of the immune response, the alteration of cell membranes, and the genetic controls of the induction of new antigens. Faculty: M. Perkins, G. Cross, Rockefeller; A. Dessein, D. Harn, D. Fearon, Harvard Medical School; C. Gitler, Weizmann Inst. of Science; M. Pereira, Tufts N.E. Medical Center; K.P. Chang, Chicago Medical School; D. Wirth, A. Spielman, S. Landfear and P. Rossignol, Harvard School of Public Health.

Embryology: *A Modern Course in Developmental Biology*
Bruce Brandhorst, McGill and William Jeffery, Texas, Directors

An analysis of the regulatory mechanisms which operate during early embryonic development. Topics to be considered are: Molecular and Cellular Aspects of Fertilization, the Activation of the Program of Gene Expression, the Generation of Embryonic Polarity, the Localization of Macromolecules and Developmental Potential, the Control of Gene Expression During Embryogenesis, and Developmental Genetics. Faculty in 1983 included L. Jaffe, Connecticut; Y. Masui, Toronto; R. Maxson, Stanford; G. Schultz, Calgary; and M. Winkler, Texas.

Microbiology: *Molecular Aspects of Cellular Diversity*
Harlyn O. Halvorson, Brandeis, Director

The primary focus is to investigate, at the molecular level, structural and functional relationships of diverse microorganisms found in nature. Emphasis will be placed on the organisms in their natural habitats with particular attention to the molecular basis of the morphological, physiological, and genetical responses to environmental changes. Faculty: E.P. Greenberg, Cornell; A. Keynan, Hebrew U.; H. Kornberg, Cambridge; J.S. Poindexter, Public Health Res. Inst.; and J. Romesser, DuPont Co.

Physiology Robert D. Goldman, Northwestern, Director

The most advanced approaches used in cell and molecular biology will be treated. The goal is to teach those techniques which are used to relate eukaryotic cell structure with function. Topics to be covered include biochemical procedures for the isolation and characterization of cytoskeletal and contractile proteins associated with microtubules, intermediate filaments and microfilaments, gene transcription, RNA processing, *in vitro* protein synthesis, light and electron microscopy, and immunocytochemistry. Faculty: Thoru Pederson and Richard Vallee, Worcester Foundation; and James Spudich, Stanford.

Costs: Tuition, $1,100; room and board from $68–$105 per week.

Financial aid is available from a variety of sources, including NI

Deadline for All Courses: February 24, 1984. For further information and application material

Circle No.16 on Reader Service Card.

Neuroscience Courses at the MBL

Spring/Summer 1984

Biophysics of Neural Function Daniel Alkon, NINCDS/MBL, Director May 7–June 3

Membrane channels, analyzed in laboratory exercises with current-, voltage-, and patch-clamp techniques, are considered in the context of functioning neural systems which underlie behavior and behavioral change. Research tutorials arranged on an individual basis. Faculty: R. Barlow, Syracuse; M. Brightman, NIH; J. Connor, Bell; C.K. Govind, Toronto; E. Kaplan, Rockefeller. Lecturers: H. Atwood, Toronto; R. Aldrich, R. DeLorenzo, H. Rasmussen, and G. Shepherd, Yale; M. Brodwick, Texas; L. DeFelice, Emory; J. Dowling and E. Kravitz, Harvard; R. French, Maryland; C. Gilbert, Rockefeller; H. Lecar, NIH; G. Pappas, Illinois; and T. Weiss, MIT. —Tuition, $600; room and board, approximately $350.

Neural Systems and Behavior Ronald Hoy, Cornell and Eduardo Macagno, Columbia, Co-Directors June 10–July 28

The central theme is the analysis of behavior in terms of the functional and anatomical organization of the nervous system. Particular emphasis is given to the plasticity and development of the nervous system and to the ontogeny of behavior. Faculty: R. Calabrese, Harvard; D. Kelley, Columbia; M. Nelson and R. Harris-Warrick, Cornell; R. Menzel and J. Erber, Free Univ. of Berlin; and B. Zipser, Cold Spring Harbor.

—Tuition $750; room and board from $68–$105 per week.

Neurobiology John Hildebrand, Columbia and Thomas Reese, NIH/MBL, Co-Directors June 10–August 25

A diversity of conceptual approaches, biological materials, and research techniques are combined to confront current problems in cellular and molecular neurobiology. There are four successive sections: physiology, biochemistry, developmental neurobiology, and neurocytology. Faculty: B. Battelle, NIH; G. Burd, Rockefeller; K. Dunlap, Tufts; G. Fischbach, Washington U.; E. Furshpan, M. Goy, D. Landis, S. Landis, S. Matsumoto, R. Nishi, D. Potter and R. Zigmond, Harvard; L. Hall, Albert Einstein; S. Huttner and P. O'Lague, UCLA; and D. Shotton, Oxford.

—Tuition $1,100; room and board from $68–$105 per week.

Neurobiology of the Leech John G. Nicholls, Biocentrum, University of Basel, Director July 31–August 20

By studying techniques using this single nervous system, students develop skills for the study of cellular neurobiology. The properties, projections, and synapses of sensory neurons, motor neurons, and interneurons are examined using electrophysiological recording and intracellular staining. Students participate in the culture of neruons, use neuron-specific monoclonal antibodies and stain monoamine-containing neurons, prepare identified neurons for electron microscopy and carry out individual projects. Lectures and discussions deal with neural development, rhythmical behaviors and their underlying circuitry, plasticity and regeneration of synapses, monoclonal antibody techniques, and optical recordings. Faculty: K. Muller, Univ. of Miami School of Medicine; W.J. Thompson, Texas; and D. Weisblat, Berkeley. —Tuition, $600; room and board, approximately $350.

NEW POST-ELECTION EDITION!

How Britain runs its science...

This highly successful wallchart has now been revised and updated to take account of changes in structure and personnel since the previous edition was published in 1981. It includes the ministerial and other changes which followed the British General Election on 9 June, 1983.

The guide provides a comprehensive survey of the administration of British science, showing the interlocking relationship between science, engineering and medical establishments. It gives a full account of the funding of science in Britain, with details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, the 75 × 95cm chart can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1983 edition is available at £3.50 or US$7.95 from Nature's offices in Basingstoke or New York.

In the UK and elsewhere: Nature, Brunel Road, Houndmills, Basingstoke, Hants, RG21 2XS, England.

In the US and Canada: Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

Cheques should be made payable to Nature.

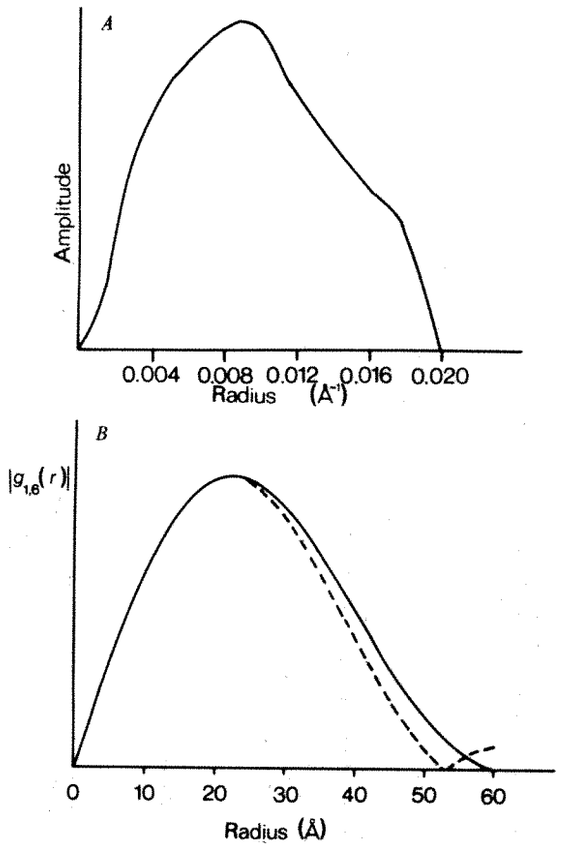

Fig. 1 *A*, The integrated intensity of the 59 Å layer line from the X-ray diffraction pattern of live relaxed frog sartorius muscle was measured, and a background was subtracted. The resulting amplitude distribution is shown. *B*, The function $g_{1,6}(r)$ (ref. 15) has then been computed using Fourier–Bessel inversion of the data shown in (*A*) (solid curve). A corresponding plot from the model of Egelman and DeRosier[3] is also shown (dashed curve). This function is proportional to the modulation of F-actin density when the filament structure is projected along the 59 Å left-handed helix. Because the true radial density distribution of the filament (derived from the equator) has not been added in, this function is zero at the filament axis. The density distribution for the model extends beyond the 49 Å outer radius of the model because of the resolution cutoff which has been imposed to make the two plots comparable.

al.[8] extends out to 0.024 Å^{-1} on the 59 Å layer line, and the resulting helical projection agrees even better with the model. This suggests that the cutoff of our observed intensity at 0.020 Å is responsible for the difference which exists between the model helical projection and the X-ray derived projection.

A second line of X-ray evidence concerns the radius of gyration of the actin filament. This quantity is equal to the square root of the second moment of the average cross-sectional density distribution:

$$\left(\frac{\int r^2\rho(r,\theta)r\,dr\,d\theta}{\int \rho(r,\theta)r\,dr\,d\theta}\right)^{1/2}$$

It has been measured to be 25 ± 2 Å (ref. 9 and R. Mendelson, personal communication). A homogeneous cylinder (whose mean radial density distribution is given by a box function) will have a radius of gyration equal to $r_{max}/\sqrt{2}$, where r_{max} is the outer radius of the cylinder. Thus, the 25 Å value obtained implies that the radius of gyration of actin is the same as that of a homogeneous cylinder of maximum radius $\sqrt{2}\times 25$ Å, or 71 Å in diameter. This value was cited by Fowler and Aebi[6] as being consistent with their 70–80 Å model. But we know, in fact, that actin is far from a solid cylinder. For one thing, it has a deep helical groove along the 59 Å helix which gives rise to the strong and broad peak along the 59 Å actin layer line. This

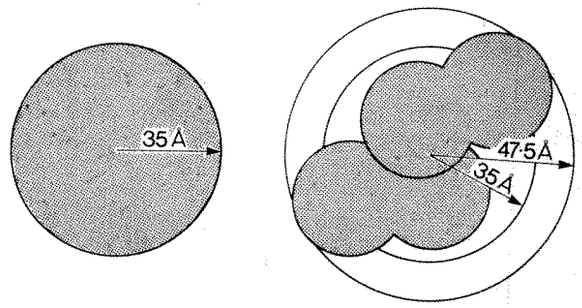

Fig. 2 The radial density distribution of two different models having the same radius of gyration (25 Å) as that experimentally determined for actin[9] are compared. *A*, A homogeneous solid cylinder. *B*, Two actin subunits from the model of Egelman and DeRosier[3], looking down the filament axis. The model uses two symmetrical spheres in the absence of any better information on which domain is the larger. The model is basically enclosed by a cylinder of 95 Å in diameter. The model's radius of gyration (25.4 Å) is equal to that of the solid cylinder shown in *A*.

is the most characteristic feature of both electron microscope transforms and X-ray patterns of actin. A consideration of how the actin subunit can be packed into a filament having such a groove suggests that proportionately more mass has been removed from the 'ideal' homogeneous cylinder at higher radius than at lower radius. This means that the mean radial density distribution will fall with radius. Therefore, the fact that actin has a radius of gyration equivalent to that of a homogeneous cylinder of 71 Å diameter is a strong argument that the maximum diameter of the actin filament is significantly greater than 71 Å. Figure 2 compares the radial density distribution of the 'perpendicular' actin model with that of a homogeneous cylinder having the same radius of gyration. The model of Egelman and DeRosier shown has a radius of gyration of 25.4 Å, in complete agreement with the measured value.

The third avenue of X-ray evidence arises from the early observations[10,11] of the existence of a sixth layer line meridional reflection in the X-ray diffraction pattern of pure F-actin gels. Such a reflection is 'forbidden' by helical symmetry, and must arise from a perturbation of the axial distribution of mass in the actin filament. Lednev interpreted this feature in terms of subunits within the actin filament being in different states. Egelman and DeRosier[12] extended this, using evidence from Mg^{2+} paracrystals and the bending of stereocilia[13] to show that the subunit within the actin filament possessed a variable tilt. They also argued that this feature, mediated by cross-bridging proteins in the stereocilia, arose only from inter-filament packing interactions in Mg^{2+} paracrystals. It is therefore important that Lednev first observed the existence of this reflection when the mean inter-filament spacing in a pure F-actin gel was slightly over 100 Å (ref. 10). At larger spacings this reflection disappeared. This was originally interpreted by Lednev to mean that this deformation of the filament structure occurred when filament surfaces were about 40 Å apart, assuming a 70 Å diameter filament (a traditional assumption). This observation is more consistent with a picture of direct contacts between 'fat' actin filaments inducing tilts of subunits within the filament. The original explanation, of filament conformation being mediated by long range forces, seems much less plausible.

Thus our determination of actin filament diameter using data from X-ray diffraction shows that the actin filament must have a diameter of about 100 Å, and that the perpendicular arrangement of subunits in the filament is required to account for this large outer diameter. Further, this orientation of the monomer is supported by image analysis of isolated actin filaments[3], S-1 decorated actin[4], and single-layered paracrystals of thin filaments[5]. The most likely origin of the parallel model of Smith *et al.*[2] remains the superposition problem associated with multiple layer paracrystals[14].

We thank Dr H. E. Huxley for support and Dr L. Amos for helpful discussions. E.H.E. is a Fellow of the Jane Coffin Childs

Memorial Fund for Medical Research. This investigation has been aided by a grant from the Jane Coffin Childs Memorial Fund for Medical Research.

Note added in proof: The radius of gyration of F-actin has recently been remeasured and found to be 25.7±0.5 Å (P. Matsudaira, J. Bordas and M. Koch, perconal communication). This is in agreement with the cited value[9], but with a significantly smaller error.

Direct observation of motion of single F-actin filaments in the presence of myosin

Toshio Yanagida, Michiyuki Nakase, Katsumi Nishiyama & Fumio Oosawa

Department of Biophysical Engineering, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka, Japan

Actin is found in almost all kinds of non-muscle cells where it is thought to have an important role in cell motility. A proper understanding of that role will only be possible when reliable *in vitro* systems are available for investigating the interaction of cellular actin and myosin. A start has been made on several systems[1–4], most recently by Sheetz and Spudich who demonstrated unidirectional movement of HMM-coated beads along F-actin cables on arrays of chloroplasts exposed by dissection of a *Nitella* cell[5]. As an alternative approach, we report here the direct observation by fluorescence microscopy of the movements of single F-actin filaments interacting with soluble myosin fragments energized by Mg^{2+}-ATP.

Nagashima and Asakura reported that single filaments of F-actin decorated with heavy meromyosin (HMM) or S-1 are directly visible under an optical microscope with dark-field illumination, although the filaments without HMM or S-1 decoration are not visible[6]. Recently, S. Asakura (personal communication) found that single filaments of F-actin, without HMM or S-1 decoration, are made visible under a fluorescence microscope by labelling with fluorescein isothyocyanate. Using the fluorescent dye, phalloidin–rhodamine, we could clearly and continuously observe the movement of single filaments of F-actin or F-actin-tropomyosin (TM)–troponin (TN) complex for more than 5 min without photobleaching. Phalloidin–rhodamine is most convenient for the present purpose, because it is specifically bound to F-actin without any influence on physiological functions of F-actin[7,8] and its fluorescence intensity is enhanced 4.2-fold by the binding.

When G-actin is polymerized in the presence of phalloidin–rhodamine, many filaments become visible under a fluorescence microscope. Figure 1 shows micrographs of phalloidin–rhodamine-labelled F-actin and F-actin–TM–TN complex in various conditions. All fluorescent filaments have the same brightness and the brightness is uniform along the filament. The number of filaments visible in the field of microscope agrees with the number expected from the concentration of F-actin. The visible filaments are not bundles of F-actin but single filaments of F-actin.

Table 1 Flexural rigidity (ε) of F-actin and F-actin–TM–TN complexes

Sample	Medium	λ (μm^{-1})	ε (10^{-17} dyn cm^2)
FA	+Ca	0.032	6.5
FA+HMM	+Ca	0.042	4.9
	+Ca+ATP	0.059*	3.5*
FA+TM+TN	−Ca	0.028	7.4
	+Ca	0.040	5.2
FA+TM+TN+HMM	−Ca	0.025	8.3
	+Ca	0.045	4.6
	−Ca+ATP	0.027	7.7
	+Ca+ATP	0.053*	3.9*
FA-PM	+Ca	0.033	6.4

The concentration of HMM was 5 mg HMM ml^{-1}. +Ca, rigor buffer +0.2 mM $CaCl_2$; −Ca, rigor buffer +1 mM EGTA; +Ca+ATP, activating buffer; −Ca+ATP, relaxing buffer. The flexural rigidity, ε, was determined by measuring the end-to-end distance, R. About 50 values of R were measured for each filament in a 2–10-s period and the mean square end-to-end distance, $\langle R^2 \rangle$, was related to a parameter of flexibility, λ, by the equation $\langle R^2 \rangle = [2\lambda L - 1 + \exp(-2\lambda L)]/2\lambda^2$ (ref. 16). The most probable values of λ were obtained from a least-square fit to the plots of L versus $\sqrt{\langle R^2 \rangle}$ of more than 10 different filaments 5–10 μm in contour length, L. The flexural rigidity, ε, was calculated from the value of λ by the equation $\varepsilon = kT/2\lambda$ (ref. 17). FA-PM, F-actin cross-linked by *p*-phenylene-*N,N'*-bis(maleimide) by the method of Knight and Offer[14].

* In the activating buffer, the motion is not a thermal one, but the apparent values of λ and ε determined by the above procedure are shown for convenience to compare the extent of bending (see text).

The thermal bending motion of the filaments is observable under the microscope. Table 1 gives the flexural rigidity of F-actin and F-actin–TM–TN complex estimated by the statistical analysis of the end-to-end distance of a number of filaments. The values of the flexural rigidity are in good agreement with those of unlabelled F-actin and F-actin–TM–TN measured by different methods[6,9–11]. This indicates that the binding of phalloidin does not affect the dynamic property of F-actin although it stabilizes F-actin against depolymerization at low ionic strength or high concentration of KI[12]. The binding of Ca^{2+} decreased the rigidity of the complex and the binding of HMM further decreased the rigidity in the presence of Ca^{2+}.

When both HMM and Mg^{2+}-ATP are added to the F-actin–TM–TN complex in the presence of Ca^{2+}, the bending motion of long filaments becomes faster and larger in amplitude, and the tumbling motion of shorter filaments becomes conspicuous. During such motions, long filaments are often broken into fragments of up to a few micrometres (Fig. 1*d*). Figure 2 shows sequences of micrographs taken to compare the bending motion of the F-actin–TM–TN filaments in a solution containing HMM and Mg^{2+}-ATP, in the absence (Fig. 2*a*) and presence (Fig. 2*b*) of Ca^{2+}. The filaments in Fig. 2*a* and *b* have same length, 10 μm. In the absence of Ca^{2+} (Fig. 2*a*), the bending motion of the first order mode has an apparent period of 3–6 s, and that of the second order mode has a period of about 0.3 s. Previously, by using dynamic light scattering, the relaxation time of the bending motion of F-actin of 2.5 μm in length was determined to be about 10 ms[9]. The above value, 3–6 s, for the filaments of 10 μm length is reasonable because the relaxation time, τ_n, of the bending motion is proportional to the fourth power of the length, as given by

$$\tau_n = \pi^{-4}(n+(1/2))^{-4}\,\zeta\,L^4\,\varepsilon^{-1} \qquad (1)$$

where n is the mode number, L the contour length of the filament, ζ the frictional constant for a structural unit and ε the flexural rigidity[9].

In the presence of Ca^{2+} (Fig. 2*b*), the apparent period of the bending motion of the first mode decreased to 1–3 s. If the bending is due to thermal brownian motion, the flexural rigidity in the presence of Ca^{2+} must be about twice as large as that in its absence, according to equation (1). However, as found in

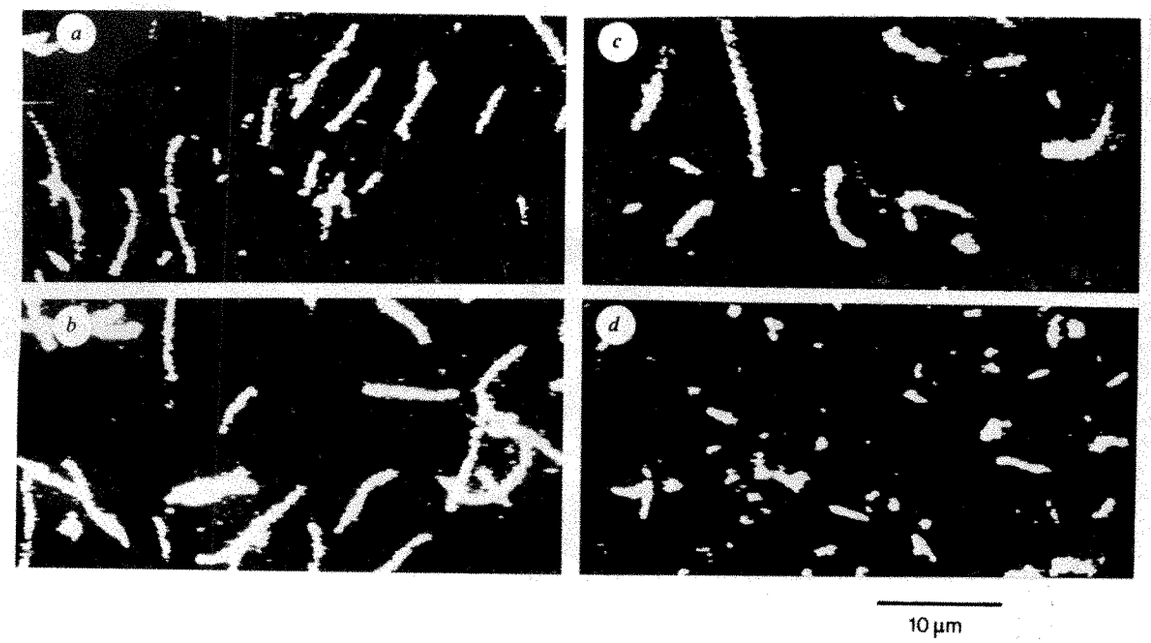

Fig. 1 Micrographs of phalloidin–rhodamine-labelled F-actin: *a* and *b* are for the F-actin in rigor buffer (0.1 M KCl, 5 mM $MgCl_2$ and 10 mM MOPS *p*H 7.0) in the absence and the presence of 10 mg HMM ml^{-1}, respectively. *c* and *d* are for the F-actin–TM–TN complexes in relaxing buffer (rigor buffer +1 mM EGTA, 3 mM ATP, 5 mM creatine phosphate and 2 mg creatine kinase per ml) and in activating buffer (rigor buffer +0.2 mM $CaCl_2$, 3 mM ATP, 5 mM creatine phosphate and 2 mg creatine kinase per ml) containing 10 mg HMM ml^{-1}, respectively. All proteins were obtained from rabbit skeletal muscle and purified according to the method described previously[10]. G-actin of 1 μM was polymerized in rigor buffer containing 1 μM phalloidin–rhodamine overnight at room temperature. TM and TN were added to the F-actin solution at a weight ratio of 1:4, respectively. For observation the solutions were diluted 50-fold in buffer and put in a gap between a glass slide and a coverslip of 50 μm in thickness. Final concentration of actin was 20 nM. β-Mercaptoethanol of 0.1–0.5% (v/v) which did not affect actomyosin ATPase activity or muscle contraction was added to the solutions to suppress photobleaching. Fluorescent F-actin or F-actin–TM–TN complexes were observed with a Nikon VFD-TR microscope equipped with epifluorescence optics, a Nikon UV-F ×100 objective (oil immersion, NA 1.3), a 100–200-W mercury arc lamp and a Nikon rhodamine filter set ($\lambda_{EX} \sim 540$ nm, $\lambda_{EM} > 580$ nm). Fluorescent images were recorded on videotape with a high-sensitivity television camera (Ikegami CTC-900) and a video recorder (National Time Laps NV8030).

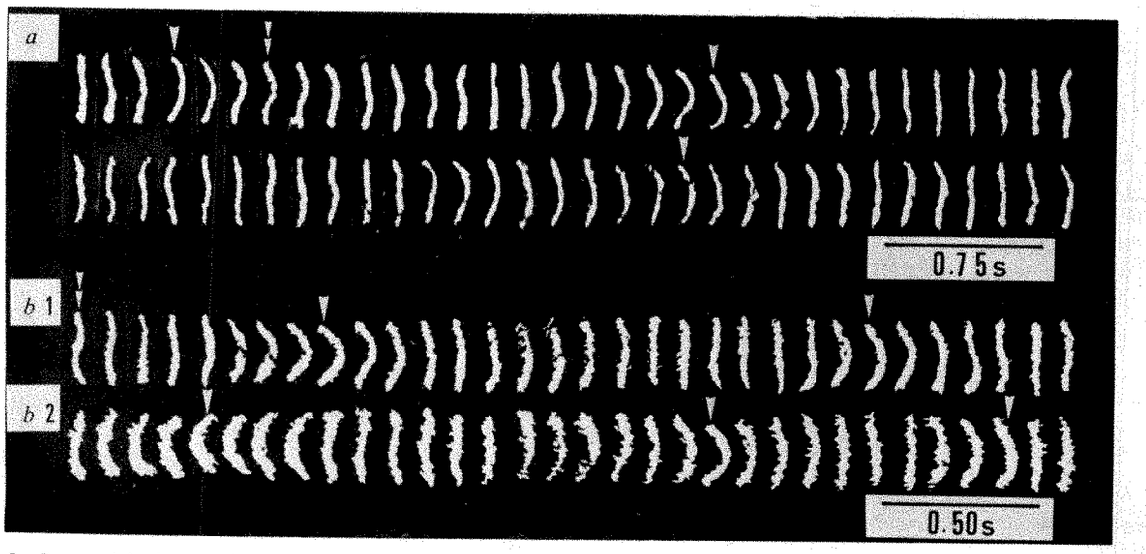

Fig. 2 Sequential micrographs of phalloidin–rhodamine-labelled F-actin having bound TM and TN in relaxing buffer +5 mg HMM ml^{-1}, (*a*) and in activating buffer +5 mg HMM ml^{-1} (*b*, 1, 2). The intervals between successive images were 0.15 s (*a*) and 0.10 s (*b*, 1, 2), respectively. The contour length of both filaments was 10 μm. Single arrows indicate first-order mode bending motion and double ones second order mode bending motion. As measured by a semiconductor thermometer, the temperature of the solution was 25 °C during illumination. No increase in the temperature of the solution during ATP hydrolysis by HMM, S-1, acto-HMM or acto-S-1 was detectable. The resolution of TV camera (1/60 s) was not high enough to record the rapid motion of filaments, especially in activated state (*b*).

Figure 2*a* and *b*, the average amplitude of bending of the filaments is distinctly larger in the presence of Ca^{2+} than in its absence. Therefore, we conclude that more rigid filaments in the presence of Ca^{2+} were forcibly bent by interaction with HMM and ATP. Conversely, it is also possible to conclude that the bending motion of the filament which is more flexible in the presence of Ca^{2+} was accelerated by interaction with HMM and Mg^{2+}-ATP. The latter case is more likely because the F-actin–TM–TN complex is more flexible in the presence of Ca^{2+} as shown in Table 1. In the present conditions (0.1 M KCl, 20 nM actin and 15 μM HMM), the rate of hydrolysis of ATP is estimated to be about 1 mole per mole actin per s (ref. 13). That is, each actin monomer is attacked by energized HMM (HMM–ADP–P_i) about once per second. The energy liberated by the hydrolysis may be (partially) transferred to F-actin to induce its active motion.

Similar results have been obtained by using pure F-actin instead of the F-actin–TM–TN complex and we have preliminary evidence that S-1 has the same effects as HMM on the motion of F-actin and the F-actin–TM–TN complex. The two-headed structure of HMM is not absolutely necessary to produce faster and larger bending motion of F-actin and the complex.

The effect of cross-linking of actin subunits by *p*-phenylene *N,N'*-bis(maleimide) (PM) on the motion of F-actin was also examined. Previously, by applying this reagent, Knight and Offer showed that the cross-linking did not change the ability of F-actin to activate myosin ATPase and induce superprecipitation, and suggested that relative motion of actin subunits was not required for the activation[14]. According to our direct observation, however, the cross-linking by this reagent does not restrict the motion of F-actin and the cross-linked F-actin has the same value of the flexural rigidity as before cross-linking (Table 1).

The present finding suggests that in an activated state, myosin heads induce local conformational changes in F-actin such as distortion or rotation of actin monomers and loosening of actin–actin bonds[8,15], which result in fast and large bending in F-actin filaments. Since F-actin has a structural polarity, the motion in F-actin could be asymmetric, if it occurred during interaction with HMM or S-1 in the presence of Mg^{2+}-ATP. However, the interaction between single F-actin filaments and soluble myosin fragments did not produce directional movement. When F-actin filaments function in living cells, they are usually found as assemblies with same polarity and often supported by some backbone such as membrane. Therefore, higher organizations of F-actin such as polar bundles may be indispensable to transformation of the activated motion in F-actin into an effective sliding force.

We thank Dr Th. Wieland for supplying us with phalloidin-rhodamine, Drs K. Hotani, O. Ohara and E. Pròchniewicz-Nakayama for many useful discussions and Dr T. J. Herbert for reading the manuscript.

Microtubules with more than 13 protofilaments in the dividing nuclei of ciliates

U. Eichenlaub-Ritter

Lehrstuhl für Zellmorphologie, Ruhr-Universität Bochum, Postfach 10 21 48, D-4630 Bochum 1, FRG

J. B. Tucker

Department of Zoology, The University, St Andrews, Fife KY16 9TS, UK

Microtubules are largely composed of proteins called tubulins. These are stacked in linear arrays called protofilaments (p). Most microtubules have precisely 13p (ref. 1). The 'incomplete' B and C microtubules (10 or 11p) of cilia, flagella, basal bodies and centrioles are widespread exceptions[2,3]. Very few examples of 'complete' microtubules with more, or less, than 13p have been found[4–7]. However, the 'ciliate cell' includes a larger number of highly differentiated types of microtubule arrays than most other cell types[8–10]. The present study was undertaken to ascertain whether there is variation in p number in two ciliates. In both, all complete cytoplasmic microtubules examined have 13p but microtubules with 13–16p are present in the nucleoplasm of dividing nuclei. These features are probably common to ciliates in general because the free-living hymenostone *Paramecium tetraurelia* and the parasitic heterotrich *Nycotherus ovalis* are not closely related in terms of taxonomic criteria[11] or life-style.

During the division of a ciliate, two main categories of microtubule arrays can be distinguished: cytoplasmic and nucleoplasmic. Nuclear envelopes remain intact and large numbers of aligned nucleoplasmic microtubules are associated with the marked elongation of dividing nuclei (Fig. 1)[12,13]. Protofilaments can usually be detected in cross-sections of microtubules fixed in the presence of tannic acid[3]. However, ciliates possess a substantial pellicle, and nuclear envelopes provide an additional barrier to tannic acid access so far as nucleoplasmic microtubules are concerned. Because of this we have had to devise a protocol for making the organisms permeable without loss of alignment or disassembly of microtubules prior to fixation (Fig. 2).

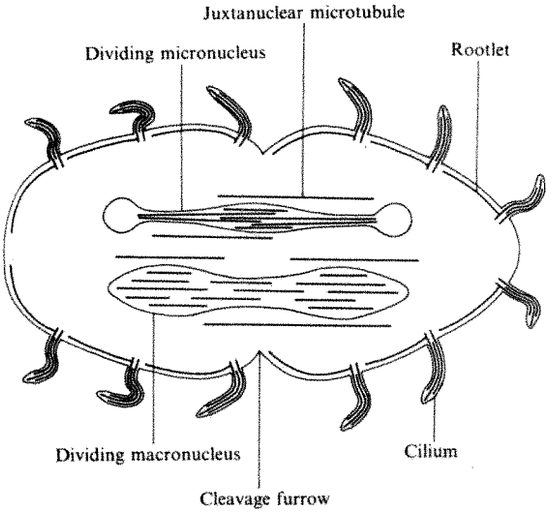

Fig. 1 The general distribution of cytoplasmic and nucleoplasmic microtubules in a dividing ciliate. The cell membrane and nuclear envelopes are depicted by thin lines. The thicker lines show the locations and orientations of microtubules. For clarity, specialized cortical organelle complexes that include microtubules such as mouthparts have been omitted.

Cytoplasmic microtubules with 13p include those that contribute to the cortical cytoskeletal complex such as cytopharyngeal microtubules[14] (Fig. 2*a*) and the A and central pair microtubules of cilia, as well as the more deeply situated juxtanuclear microtubules (Fig. 1) that run very closely alongside the outer surfaces of dividing nuclei (Fig. 3*f*). In *Paramecium* there is a set of cortical 'cytospindle' microtubules[15] that is probably a type of basal body rootlet array. Like most nucleoplasmic microtubules, and unlike most of the other cytoplasmic microtubules, they are only present during cell division and apparently promote elongation [of the dividing cell body][8,15,16]. Nevertheless, they have 13p.

The p number that predominates in dividing micronuclei changes as mitosis proceeds. This is correlated with a marked switch in the organization of nucleoplasmic microtubules during micronuclear mitosis. During the earlier stages (prophase–metaphase) spindle architecture is similar to that of mitotic spindles

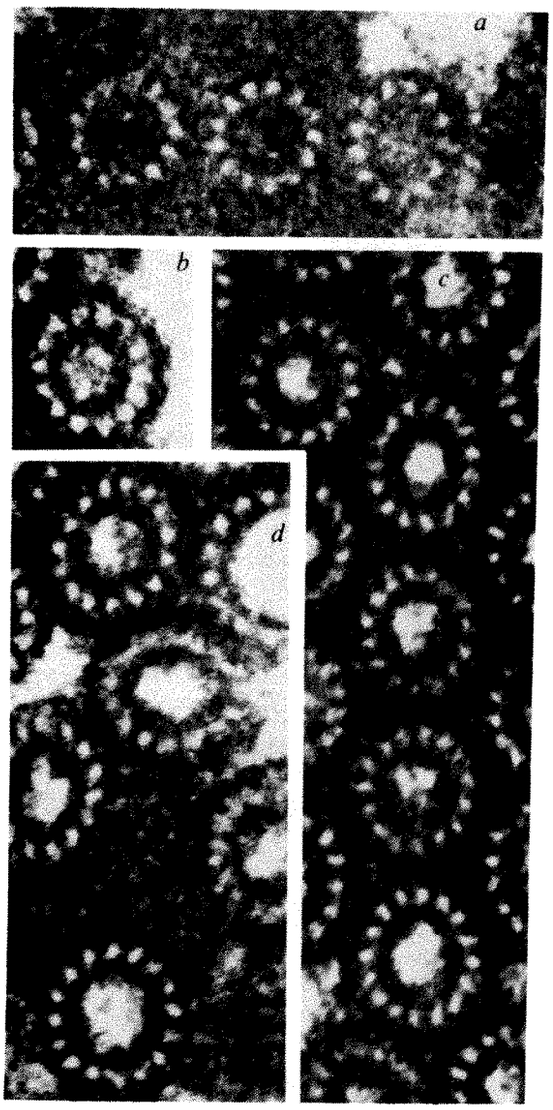

Fig. 2 Cross-section of microtubules in *P. tetraurelia*. All ×625,000. Organisms were permeabilized for 90 s by suspension in a solution of the non-ionic detergent NP40 (0.05%) buffered with the microtubule-stabilizing buffer PM2G[26] and then fixed for 1 h in a solution buffered with cacodylate (0.15 M, *p*H 7.2) containing glutaraldehyde (2.5%) and tannic acid (8%). After rinsing with five changes of cacodylate buffer at 4 °C for 12 h the organisms were post-fixed for 30 min in cacodylate-buffered osmium tetroxide (1%). Subsequent preparation for electron microscopy was as described previously[17]. *a*, Cytoplasmic microtubules with 13 protofilaments in part of a cytopharyngeal microtubule ribbon. *b–d*, Spindle microtubules in micronuclei at the same late anaphase stage as Fig. 4*b* showing: *b*, a 14 protofilament microtubule; *c*, microtubules with 15 protofilaments and one with 16 (at bottom); *d*, a microtubule with 15 protofilaments (at top) and one with 16 (at bottom).

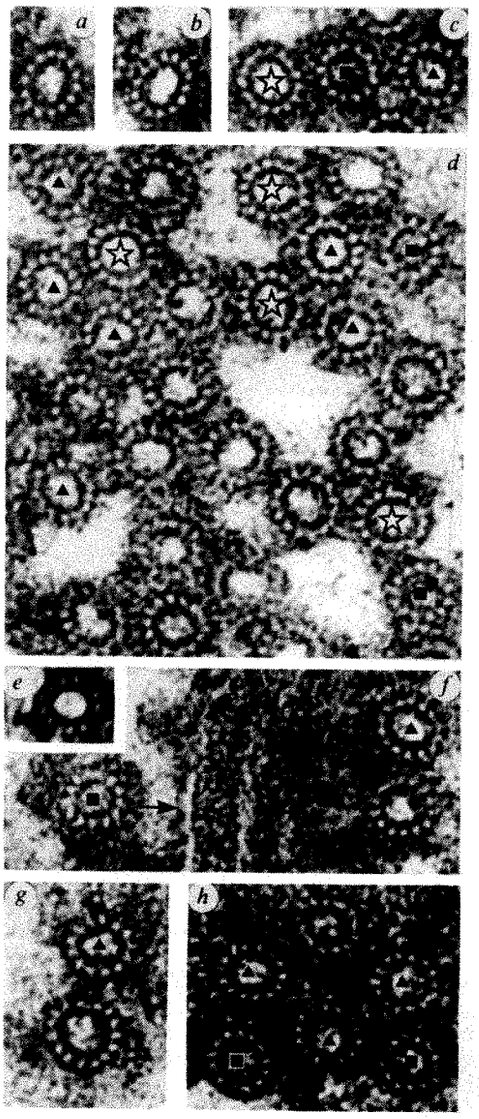

Fig. 3 Cross-sections of microtubules with 13 (■), 14 (▲) and 15 (☆) protofilaments in *N. ovalis* prepared for electron microscopy as described in Fig. 2 apart from the use of NP40 at a concentration of 0.1%. All ×370,000. *a–d*, spindle microtubules in micronuclei at late anaphase showing *a*, *b*, microtubules with 14 protofilaments, *c*, *d*, microtubules with three different protofilament values in close proximity to each other; *e*, a kinetochore microtubule with 13 protofilaments in a metaphase micronucleus; *f*, a juxtanuclear cytoplasmic microtubule (■) positioned closely alongside the envelope (arrows) and nucleoplasmic spindle of an elongating micronucleus, *g*, *h*, microtubules in dividing macronuclei. The microtubule nearest the bottom of *g* has at least 15 protofilaments.

in general (Fig. 4*a*), although there are no centrioles at spindle poles[17]. The vast majority of microtubules have 'conventional' diameters of 24 nm; in *Nyctotherus* (no data for *Paramecium*) they have 13p (Fig. 3*e*) and can be induced to disassemble by exposure to low temperature (0 °C) and antimitotic drugs[18]. However, anaphase B (chromatid separation due to spindle elongation[19]) is especially pronounced; micronuclei become dumb-bell-shaped at this stage of mitosis (Fig. 1). A compact bundle of well-aligned microtubules (Fig. 4*b*) extends along the mid-portion of a micronucleus throughout the period of rapid[20] and marked elongation. In *Paramecium* most of these microtubules have diameters, up to 32 nm, that are detectably greater than 24 nm[12,21], while in *Nycototherus* they are cold and drug stable[18] unlike those that predominated earlier. Furthermore, most of the microtubules have more than 13p. Microtubules with 15p predominate in *Paramecium* (Fig. 2*c*, *d*) and some with 16p (Fig. 2*c*, *d*), 14p (Fig. 2*b*) and 13p are also present. In *Nyctotherus* most of the microtubules have 14p (Fig. 3*a–d*) but microtubules with 15p and 13p (Fig. 3*c*, *d*) also occur.

At no stage does macronuclear 'amitosis' involve the construction of a microtubule array that can be regarded as a mitotic spindle, although events are somewhat more orderly than was once supposed[20]. Microtubules with 13–16p are present (Fig. 3*g*, *h*) in the dividing macronucleus of *Nyctotherus*. Only 13p microtubules have been detected in *Paramecium* macronuclei to date (however, few unequivocal assessments of p numbers have been possible because the microtubules are not well aligned after organisms have been made permeable and fixed).

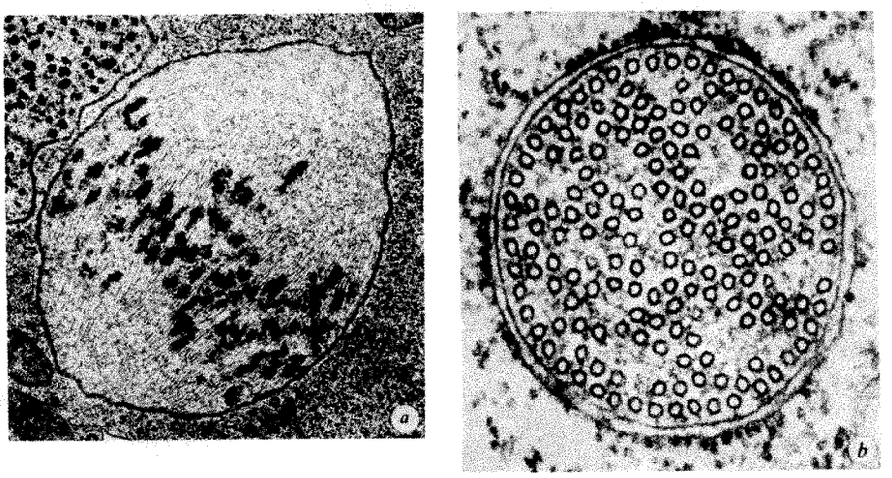

Fig. 4 *a*, Longitudinal section through a micronucleus in *P. tetraurelia* that is either approaching metaphase or has just embarked on anaphase. The clumps of dense material concentrated near the equator represent condensed chromatids. ×10,500. *b*, Cross-section of a nearly fully elongate micronuclear spindle in *P. tetraurelia*. The well-aligned spindle microtubules are surrounded by the nuclear envelope. Differences in microtubule diameters are apparent. ×70,000.

This is the first report of complete microtubules with p numbers other than 13 occurring in unicellular organisms and in association with mitosis. It also provides the first example of a situation in which most of the microtubules that assemble in normal conditions *in vivo* are composed of 14p (Fig. 3*d*) (only one 14p microtubule has previously[4] been found *in vivo*), and striking instances of variation in p number for microtubules in close spatial association (Figs 2*c*, *d* and 3*c*, *d*, *h*). The few examples, and puzzling occurrence, of complete microtubules with more (14p–16p)[4–7] or less (11p, 12p)[4,6] than 13p documented so far (from representatives of four animal phyla including a mammal[7]) suggest no immediately obvious reason why some microtubules have a p value other than 13. Variation in p number is evidently not a commonly exploited basis for the functional differentiation of microtubules. For example, the complete cytoplasmic microtubules of *Paramecium* and *Nyctotherus* are interconnected in very different ways, are structurally associated with a diversity of other cell components, and almost certainly perform a wide range of different cytoskeletal and mechanochemical functions in the various arrays in which they occur[8,13,14,20,22]—yet they are all apparently composed of 13p.

At least some of the tubulin in the 15p spindle microtubules of *Paramecium* is serologically related to some of that in the organism's 13p cytoplasmic microtubules[15]. However, some of the 'protofilaments' apparent in certain flagellar microtubules after fixation in the presence of tannic acid apparently include proteins other than tubulin[23,24]. Variation in p number may be just a crude preliminary indication of the true diversity of microtubule architecture that abounds.

There is evidence that p number is determined *in vivo* when microtubule assembly is initiated and that its specification originates from microtubule-organizing centres[25]. Is the situation in ciliate nuclei sometimes like that during *in vitro* microtubule assembly when microtubule-organizing centres and p number fidelity are both lacking? There is temporal control of the p number that predominates during micronuclear mitosis in *Nyctotherus* as reported above. Preliminary indications of positional control for nucleoplasmic microtubules with different p numbers in both organisms are emerging. Further analyses of nucleoplasmic microtubules in ciliates should be of especial value in further elucidating the spatial control and functional significance of variation in microtubule protofilament numbers.

Weaver mutation has differential effects on the dopamine-containing innervation of the limbic and nonlimbic striatum

Suzanne Roffler-Tarlov & Ann M. Graybiel

Departments of Neurology and Anatomy, Tufts University School of Medicine, Boston, Massachusetts 02111, USA and Department of Psychology and Brain Science, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Ungerstedt[1] observed that the dopamine-containing innervation of the forebrain can be divided into two parts: a nigrostriatal system, originating mainly in the pars compacta of the substantia nigra and innervating the caudoputamen; and a mesolimbic system arising mainly in the ventral tegmental area and innervating the nucleus accumbens and olfactory tubercle. This classification has since been modified and extended with the discovery of the mesocortical dopamine system[2,3]. The original distinction between nigrostriatal and mesolimbic systems nevertheless was pivotal in suggesting that the basal ganglia are related to limbic as well as to sensorimotor functions, and remains of interest because dopaminergic mechanisms may be implicated not only in the aetiology of sensorimotor impairments such as those of Parkinson's disease[4], but also in neuropsychiatric disorders such as schizophrenia[5–7]. The striatal targets of the mesolimbic and nigrostriatal systems are now known to be distinct also in terms of forebrain connections, despite some overlap of fibre projections[18,19]. The nucleus accumbens–olfactory tubercle region and abutting caudoputamen (together called the 'ventral' or 'limbic' striatum) are characteristically related to limbic parts of the

forebrain, whereas the large remainder of the caudoputamen (the 'dorsal' or 'non-limbic' striatum) is most closely related to sensorimotor regions[19,20,34]. We report here evidence that the mesolimbic and nigrostriatal systems are differentially affected in the mutant mouse *weaver*, and in particular that dopamine is severely depleted in the dorsal striatum of weaver but relatively spared in the ventral striatum. We conclude that dopamine-containing fibre systems innervating the limbic and non-limbic striatum can be influenced separately in genetic disease and that genetic control, whether direct or indirect, may be exerted at the single-gene level.

Weaver (*wv*) an autosomal recessive mutation in the mouse, has been intensively studied because of its effects on the cerebellum. The weaver disease is expressed in the cerebellum early in postnatal life when most granule cells die in their proliferative zone after failing to migrate to the internal granular layer[8]. Quite recently it has been discovered that the weaver mouse also suffers a severe deficiency of dopamine in the forebrain[9,10]. This finding prompted the present study, in which we sought to determine the specific extent and location of this neurotransmitter defect in the weaver striatum. Biochemical and anatomical observations were made on homozygous weaver animals (*wv*/*wv*) and heterozygous littermate controls (+/*wv*) of both sexes obtained by mating C57BL6/CBA (+/*wv*) heterozygotes purchased from the Jackson Laboratories (Bar Harbor, Maine). Offspring were taken for study at 1–9 months of age. Homozygous weaver animals were identified behaviourally by their severe ataxia, hypotonia, and fine tremor[8]. Heterozygote littermates have no such obvious behavioural abnormalities but do have moderate cerebellar atrophy and were identified by retrospective examination of the cerebellum[11,12]. Homozygous (+/+) littermates have not yet been examined.

For the biochemistry, whole-region dissections of the caudoputamen, nucleus accumbens, olfactory tubercle and midbrain were made from 420-μm-thick transverse slices cut from 17 weaver and 17 control brains hardened *in vivo* by transcardial perfusion with ice-cold phosphate-buffered saline (0.1 M PO_4, 0.9% saline) under conditions of barbiturate (Nembutal) anaesthesia[13] (see Fig. 1). Whole-retina samples were also taken from some animals, so that the values for dopamine in the basal ganglia could be compared with those of the dopamine-containing amacrine cell population in the retina. Catecholamines were extracted from the isolated brain regions and retinas by homogenization in 0.1 M $HClO_4$. The dopamine in the supernatant was isolated using alumina mini-columns and was measured by electrochemical detection following separation by high performance liquid chromatography[14]. The protein content of the precipitate was determined by the method of Lowry *et al.*[15].

For the anatomy, 30 μm-thick sections were cut in a cryostat from frozen unfixed brains (13 weavers, 14 littermate controls), thaw-mounted onto slides and processed by de la Torre's glyoxylic acid method[16] for the visualization of catecholamine-induced fluorescence. Sections were viewed and photographed under fluorescent illumination with the aid of a Leitz Ploemopak.

Table 1 summarizes the biochemical findings for all mice studied. In the controls, the concentrations of endogenous dopamine extracted from the caudoputamen, nucleus accumbens and olfactory tubercle were similar, though values for the caudoputamen were slightly higher than those for the ventral subdivisions. Dopamine levels for all three striatal districts were, as expected[17], high (>200 pmol per mg protein) relative to values for the midbrain and retina (~7 pmol per mg protein). Measurements of samples from the weaver mice confirmed that there are reduced levels of dopamine in the striatum of this mutant[10] and further demonstrated that the defect is neither shared by all dopaminergic neurons in the central nervous system nor equivalent in all regions that are affected. First, the dopamine content of the weaver retinas was indistinguishable from that of control retinas, suggesting that the dopamine-containing amacrine cells are normal in these mutants. Second, there was a remarkable non-uniformity in the depletion of dopamine in the weaver striatum, with by far the largest reduction in dopamine levels appearing in the dorsal striatum.

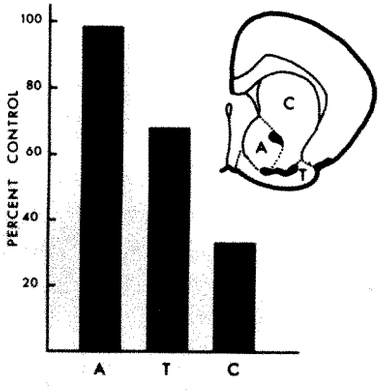

Fig. 1 The bar graph summarizes measurements, expressed as % of littermate control values, of the concentrations of endogenous dopamine extracted from the nucleus accumbens (A), olfactory tubercle (T) and caudoputamen (C) of weaver mice. Thirty-four mice (17 weaver, 17 control) were used. All brain samples were obtained from mice anaesthetized with sodium pentobarbital (Nembutal, 40 mg per kg) and perfused through the heart with chilled phosphate-buffered saline[13]. The cold-hardened brains were removed and placed on the stage of a tissue sectioner, were covered with agar and were cut into a series of 420-μm-thick transverse slices. The face of each slice was viewed through a dissecting microscope with indirect illumination from below so that nuclei and fibre tracts could be distinguished by their differential translucency. Whole-region dissections of the caudoputamen, nucleus accumbens and olfactory tubercle were made by removing the structure from each level at which it appeared with fine cold blades. The inset to the right of the bar graph shows the borders followed in removing the three striatal districts from a representative slice. Samples containing the caudoputamen, nucleus accumbens and olfactory tubercle were homogenized in 0.1 M perchloric acid. After centrifugation, the dopamine in the supernatant was isolated on alumina mini-columns, separated by high performance liquid chromatography and measured electrochemically[14]. The protein content of the precipitate was determined by the method of Lowry *et al.*[15]. Fourteen of the weaver-littermate pairs were between 1 and 4 months of age. Three pairs were 6–9 months old. As no differences between the young and older animals were found, values for all ages are shown together. See Table 1 for values expressed as pmol dopamine per mg protein.

Figure 1 summarizes the differential loss of dopamine in the striatum and shows an example of the boundaries followed in separating the three striatal subdivisions studied. The most striking contrast was between the concentrations of dopamine in the caudoputamen and in the nucleus accumbens: there was a 67% loss of dopamine in the weaver caudoputamen relative to control values, but virtually complete sparing of dopamine in the weaver nucleus accumbens. The olfactory tubercle showed an intermediate effect (32% loss). This differential pattern of biochemical abnormality was already established in the 1 month-old weavers and appeared unchanged in the oldest animals studied (9 months). As shown in Table 1, the dopamine concentration in the weaver midbrain was also abnormal, being reduced 31% relative to the control values at all ages sampled in the 1 to 9 month interval.

Measurements of protein made in weaver and in control mice (Table 1) point to a slight but consistent atrophy of the weaver caudoputamen, where protein content was reduced by 15%. By contrast, the protein concentrations measured for the nucleus accumbens and olfactory tubercle, and for the midbrain, were normal, indicating that the volumes of these regions were unaffected in the mutants. These results suggest that the striatal abnormality in the weaver mouse includes a component of tissue loss and that this, like the defect in dopamine, is expressed most strongly in the dorsal striatum.

The neurotransmitter defect in the weaver striatum was vividly demonstrated in the histofluorescence sections prepared

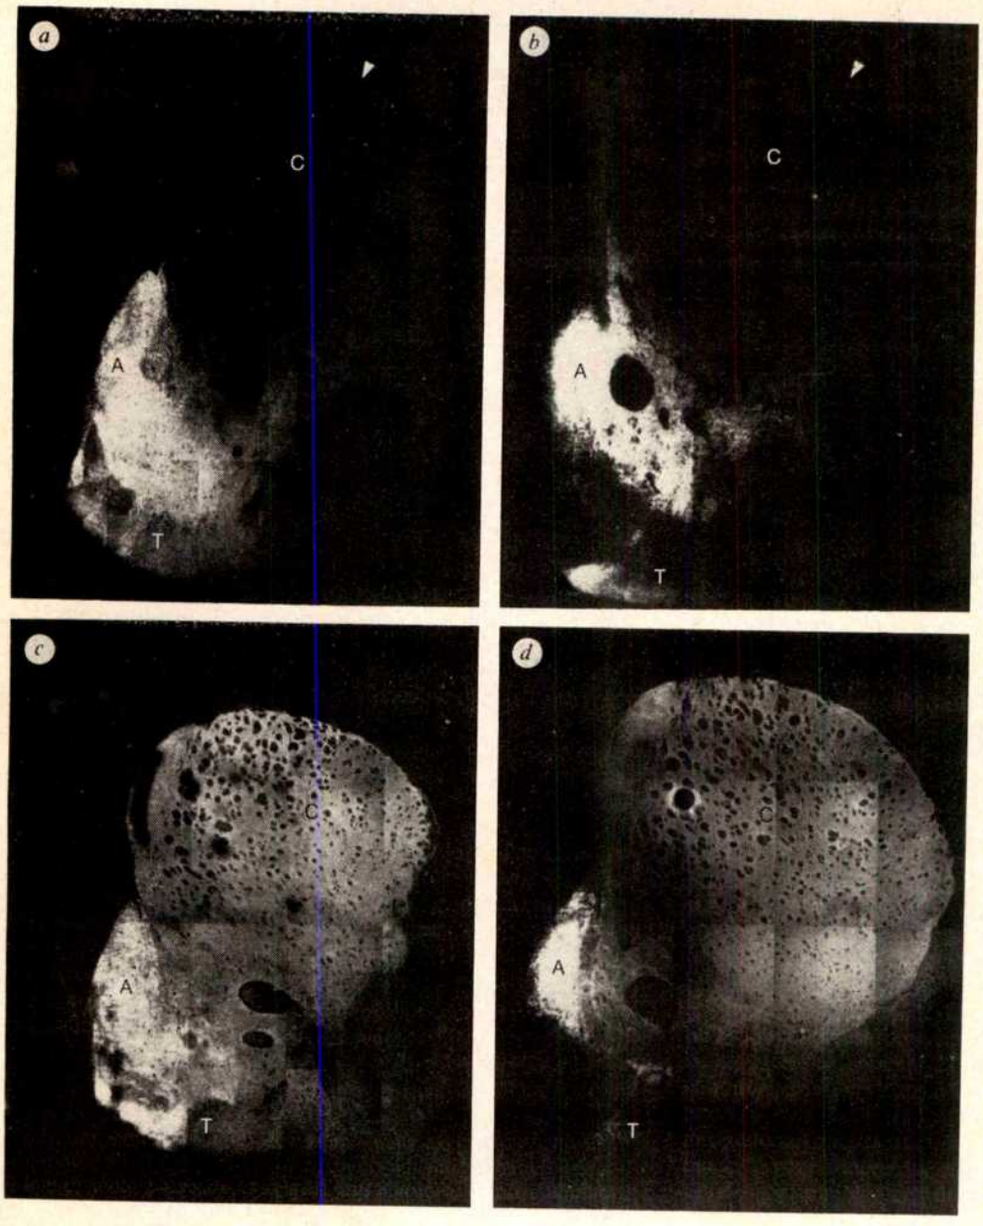

Fig. 2 Montage-photographs illustrating catecholamine-induced fluorescence (white) in the striatal complex of a 1-month-old homozygous weaver mutant mouse (*a*, *b*) and its heterozygous littermate control (*c*, *d*). Rostral cross-sections (A and C) are at midlevels of the nucleus accumbens (A). Caudal cross-sections (B and D) are near caudal tip of nucleus accumbens and olfactory tubercle (T). The sections from the control brain show the bright fluorescence distinguishing the entire striatal complex from surrounding tissue and the brilliant fluorescence in nucleus accumbens and medial olfactory tubercle. By contrast, in the sections from the weaver mutant, fluorescence is very weak in the caudoputamen (C) but appears normal in the nucleus accumbens and probably also the medial part of the olfactory tubercle. Note residual fluorescence in most ventral caudoputamen, which is considered together with the nucleus accumbens and olfactory tubercle as part of the ventral striatum.

for the anatomical experiments. This is evident in the montage-photographs of Fig. 2, which illustrate transverse sections through two levels of the striatum in a 1 month-old weaver mouse and in its littermate control. In the control brain (Fig. 2*c* and *d*) the catecholamine-induced fluorescence is brilliant in the nucleus accumbens and medial olfactory tubercle and bright throughout the rest of the striatum. As a result, the non-dopaminergic fibre bundles piercing the striatal tissue stand out as dark against the neuropil. The intensity of fluorescence varies somewhat within the caudoputamen and markedly within the nucleus accumbens and olfactory tubercle. Some of this heterogeneity almost certainly reflects local differences in innervation density or type, especially in the accumbens and olfactory tubercle. The details of the patterning varied from section to section.

In the weaver brain (Fig. 2*a*, *b*) the entire dorsal part of the caudoputamen is darkened. The fluorescence is not completely missing in this region, because there still is a discriminable difference in brightness between striatal and non-striatal tissue (see arrows). Even so, compared to that in the littermate control, the fluorescence clearly is very weak dorsally and hardly visible dorsolaterally. By contrast, in the most ventral part of the caudoputamen, below the depth-level of the anterior commissure, the intensity of fluorescence approaches control levels, and both the nucleus accumbens and the medial part of the olfactory tubercle show a brilliant apparently normal fluorescence. In the nucleus accumbens of the weaver, the degree of heterogeneity in the distribution of fluorescence resembles that in the control (contrast Fig. 2*a*, *c*). The relative brightness in at least the medial part of the olfactory tubercle also seems similar.

A similar loss of fluorescence in the caudoputamen and sparing of fluorescence in the nucleus accumbens and medial olfactory tubercle was observed in all the weaver brains examined and in each, a gradient of loss was evident in the caudoputamen, the least dimming of fluorescence being ventral. The patterns in the olfactory tubercle were more variable, for although the medial part of the tubercle always seemed to be spared, fluorescence laterally was more difficult to see in some weaver brains than in others. Variability may partly have been associated with edge artefacts produced at the time of sectioning.

To a remarkable degree, the topography of dopamine loss in the weaver striatum respects the subdivisions of the striatum drawn on the basis of its nigrostriatal and mesolimbic inputs and represented in the terms dorsal (non-limbic) and ventral (limbic) striatum. It is particularly striking that in the weaver mouse, the region of remaining fluorescence exceeds the nucleus accumbens and medial olfactory tubercle to include the ventral part of the caudoputamen, just as the mesolimbic system (as

Table 1 Content of dopamine and protein in three striatal regions, midbrain and retina of weaver and littermate control mice

Extractions and measurements of dopamine and protein were made following whole-region dissections of striatum and midbrain as described for Fig. 1. The retina was dissected with the aid of a microscope after removing the eye and bissecting the retina with sharp blades inserted into the optic stalk. A total of 17 control and 17 weaver mice were used but not all regions were examined in each animal. For the three divisions of striatum, dopamine content was measured separately in the right and left hemispheres. There were no left-right differences, thus dopamine and protein values from right and left are combined in the table. Animals ranged in age from 1 to 9 months with most being under 4 months of age. All regions were examined in both young and old animals. No differences were detected between younger and older animals, and thus data from all animals were pooled. Values shown are mean ± standard error of the mean. The numbers in parentheses represent numbers of samples. Statistical comparisons were conducted with Student's two tailed t-test. $^*P < 0.001$.

charted in the rat) projects to the ventral caudoputamen in addition to the accumbens-tubercle proper[18–21]. Although a detailed mapping is still needed, we conclude that the weaver disease affects dopamine levels mostly in the dorsal striatum and spares dopamine mostly in the ventral striatum. This suggestion is strengthened by our preliminary observations on the distribution of tyrosine hydroxylase-like immunoreactivity in the weavers, which also shows a sharp depletion dorsally (manuscript in preparation).

These findings strongly suggest that the nigrostriatal and mesolimbic dopamine systems are differentially vulnerable in genetic disorders. Just how the weaver mutation affects the dopamine-containing neurons in the midbrain, however, is not yet clear. In the cerebellum, the extensive death of granule cells in the early postnatal period is thought to result from a failure of granule cells to migrate from their proliferative zone[22]. Most evidence shows the migratory defect to be a consequence of a direct action of the weaver gene on the granule cells[23–26] but the possibility of a direct effect on the Bergmann glial guide fibres has not been excluded[24,25]. Schmidt *et al.*[10] have suggested that the dopamine defect in weaver is also developmental because striatal dopamine levels are nearly normal in neonatal weavers but fail to increase with age. These authors describe cell loss in the adult weaver substantia nigra pars compacta, but report normal concentrations of dopamine in the brainstem. Our own work shows that the concentration of dopamine in the weaver midbrain is decreased by about one-third (31%) relative to control values (Table 1). In the anatomical material, fluorescing neurones can be detected in each of the midbrain dopaminergic cell groups, including the pars compacta of the substantia nigra, but results from a quantitative study, now under way, will be needed to determine whether a particular subpopulation of dopaminergic neurones is missing in the weaver. Given the pattern of striatal loss, an abnormality of neurones in the substantia nigra's pars compacta would clearly be most likely.

Plausible alternatives to cell loss include not only metabolic defects but also abnormality of certain axon-collateral systems, as has been suggested for the mutant mouse tottering[27]. Any of these factors could reflect a primary action of the weaver gene on midbrain neurons and glia (for example, on cells migrating at a particular time) or could represent effects secondary to changes in the forebrain (for example, in response to specific defects in target cells or receptors). The possibility of a differential loss of dopamine receptors in the dorsal striatum deserves special emphasis because Boehme and Ciaranello[28] have shown that strain differences exist in striatal dopamine receptor binding in inbred mice, and that there is independent genetic control of receptors in the olfactory tubercle and more dorsal striatum. A study of the distribution of dopamine receptors in weaver is clearly needed. Strain differences in the numbers of dopamine-containing neurones in the midbrain and in corresponding differences in midbrain tyrosine hydroxylase activity[29] have also been reported, but apparently the effects are similar in the substantia nigra and ventral tegmental area[30].

A general implication of the present findings is that genetic control of dopaminergic systems in the forebrain may be exerted separately on subunits defined in functional[31], pharmacological[32], and anatomical[1] terms. Of the parts of the dopamine-recipient forebrain so far analysed in weaver, the nucleus accumbens is singled out as being fully spared a dopamine deficit, the dorsolateral caudoputamen as being most severely affected. No hereditary disease in the human has yet been shown to affect different parts of the striatal dopamine mechanism with such selectivity. The findings in weaver point to the potential for such dissociations, however, and this is of interest given the suspected differential contributions of dopaminergic fibres projecting to the dorsal and ventral striatum in modulating the organization of movement patterns and their motivational contexts[31]. In this regard it is striking that in Huntington's disease, an autosomal dominant disorder in which the striatum atrophies, neurones in the nucleus accumbens are spared relative to those in the caudoputamen[33] just as the content of dopamine and of protein in the weaver nucleus accumbens is spared relative to that in the weaver caudoputamen. The weaver disorder might thus hold clues to general patterns of tissue and neurochemical loss produced in the striatum in inherited extrapyramidal diseases.

We thank Dr William Shucart and the Department of Neurosurgery at Tufts New England Medical Center and the Wills Foundation for support to initiate this study. We are grateful for support from the Lena Marcus Fund, the Edith C. Blum Foundation, NIH 2S07-RR05598 and NIH EYO 2866 and thank Ms Dianne Sahagian and Mr Alfred Giuffrida for technical support and Mr Henry Hall for photography.

Adrenal chromaffin cells form functional cholinergic synapses in culture

M. Ogawa*, T. Ishikawa† & A. Irimajiri

Department of Physiology and †Department of Anatomy, Kochi Medical School, Nankoku, Kochi 781-51, Japan

Adrenomedullary cells and autonomic ganglion cells originate from the neural crest. Both cell types synthesize, store and release catecholamines; however, their structural and functional properties are distinctly different. Aloe and Levi-Montalcini[1] have shown *in vivo* that when the adrenal medulla is exposed to exogenous nerve growth factor (NGF) most cells differentiate into neuronal cells substantially similar to sympathetic neurones. Experiments *in vitro*[2–7] have also shown that neonatal as well as adult adrenal chromaffin cells and their neoplastic correlate (PC12 cells) undergo neurone-like morphologic differentiation in response to NGF. From these morphological and biochemical studies alone, however, it remains uncertain whether the functional neuronal transformation is also accompanied. We report here that the adrenal chromaffin cells in culture can differentiate into neuronal cells having functional synapses which were found to be cholinergic in nature. Furthermore, the type of synaptic vesicles in the newly formed synapses was apparently dependent upon K^+ levels in the culture medium.

Adrenal glands were removed aseptically from 8- to 10-day-old Wistar strain rats of either sex. Medullae were carefully freed from capsular and cortical tissue by using a pair of knives and/or fine tungsten needles under a dissecting microscope, and then incubated with dispase (1,000 U per ml culture medium; Godo Shusei) for 1 h at 36 °C. After washing by centrifugation and resuspension, the cells were seeded onto 35 mm Falcon dishes containing a control culture medium (Dulbecco's modified Eagle's medium (DMEM) supplemented with 20% fetal calf serum). Cultures were maintained at 37 °C in a water-saturated atmosphere of 95% air and 5% CO_2; the medium was changed every 2 to 3 days. A fraction of 2.5S NGF, prepared from the submandibular glands of adult male mice[8], was added at a concentration of 10–100 ng per ml of medium throughout the culture period. Glass micropipettes filled with 4 M potassium acetate (electrode resistance, 20–60 MΩ) were used for both recording membrane potential and passing current by means of a high input-impedance amplifier with the bridge circuit.

As regards purity of the cell populations thus prepared, an exhaustive, phase-microscopic surveillance was routinely made at least twice (on days 3 and 6 of culture) for every preparation of medullary cells; this was possible because of the relatively low density of the cells plated ($1–3\times10^3$ cells per dish). The surveillance revealed that the maximum contamination by non-chromaffin, polygonal, neuronal cells having large nuclei with conspicuous nucleoli was 0.3% (at most 3 neuronal cells per dish), a result in good agreement with Unsicker *et al.*[2], who reported a value of 0.25% (~50/20,000) for the neuronal contamination. This value, together with histochemical evidence (Fig. 1*B*, *C*), ensures the present study from the possible risk of selectively impaling the originally neuronal cells. This latter risk could also be evaded by an omission of NGF from the early stage of cell culture because under that condition neuronal contaminants, if any, would not have survived[9]. The rat adrenal chromaffin cells, as shown with human chromaffin cells[4], survived more than 20 days in culture without NGF. Cultures to which NGF was added during the second week contained approximately the same number and percentage of process-forming cells as cultures in which NGF was added at the beginning of the culture period. The only difference was that cholinergic synaptic interactions were first detected around 20 days (see below).

Shortly after the individual or small groups of cells had settled down onto the dish surface, the initially dispersed chromaffin cells showed a tendency to adhere to each other to form numerous large cell clusters, and fine unmyelinated processes concomitantly began to grow out from the cell soma. Such processes continued to grow and the final dense networks of neurites were usually formed after 2 weeks in culture (Fig. 1*A*). Fluorescence cytochemistry similar to that used by Unsicker *et al.*[2,3], revealed that almost all of the clustered cells at this stage still retained the chromaffin nature as judged from their strong catecholamine fluorescence (Fig. 1*B*, *C*). Around the end of 2 weeks or later, examination under the electron microscope (Fig. 1*D*) revealed the formation of some synaptic structures or varicosities that contained abundant clustered small clear vesicles (40–50 nm in diameter) and a few large dense-cored vesicles (~90 nm). The former vesicles are similar in size to vesicles usually observed in the synapses of cultured sympathetic neurones[10,11]. Note also the occurrence of intermediate organelles in cells at this time (Fig. 1*E*). There are now pleomorphic dense-cored vesicles. These may reflect the transition from a typical chromaffin granule inclusion to the neuronal synaptic organelles, including round electron-lucent and dense-cored vesicles.

Synaptic interaction between the chromaffin cells was tested by impaling, with microelectrodes under visual control, pairs of cells randomly selected from two neighbouring clusters. As shown in Fig. 2*A*, intracellular stimulation of cell 2 (c2) elicited an excitatory postsynaptic potential (e.p.s.p.) in cell 1 (c1) with a delay of 3.7 ms, which, in turn, occasionally triggered an action potential. When examined in a pair of nearest clusters of 4 weeks culture, such evoked e.p.s.ps were recorded from 36 pairs of cells out of 50, including 17 pairs which exhibited 'reciprocal' synaptic interaction. This observation also supports our contention that the events described here are associated with the chromaffin cells but not with the neuronal contaminants. The following observations indicate that the synaptic transmission involved was chemically mediated: (1) a delay of a few milliseconds between firing in the presynaptic cell and depolarization in the postsynaptic cell, (2) no passive transfer of hyperpolarizing

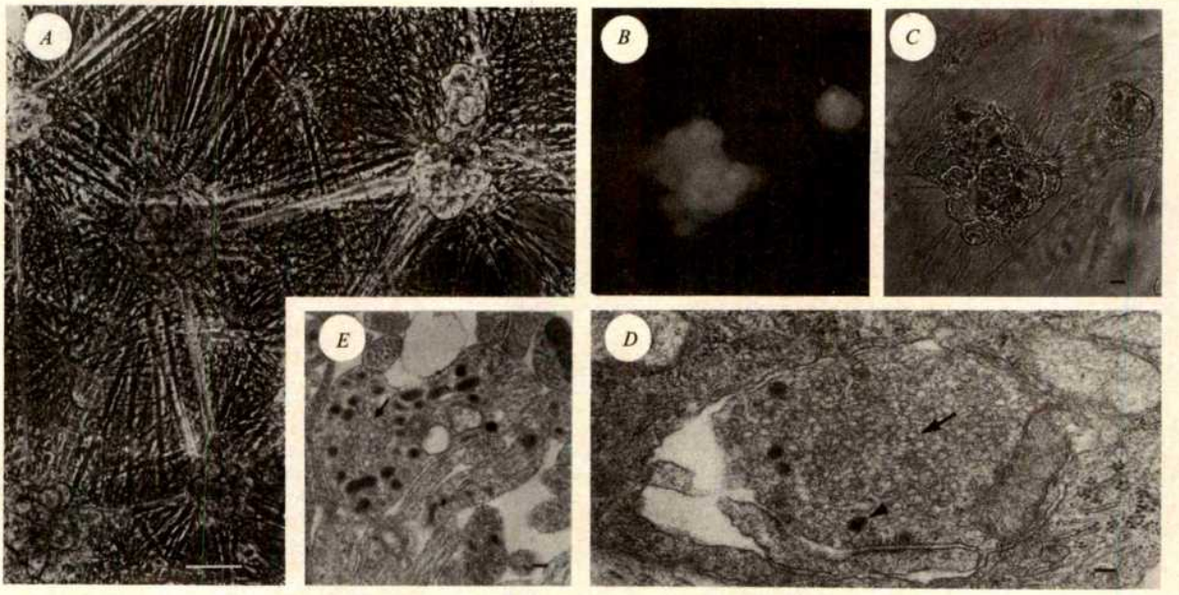

Fig. 1 ***A***, Phase-contrast micrograph of chromaffin cells cultured with NGF for 30 days. The cells, immediately after dissociation, assumed a round shape with no stumps of processes. In 1 week of culture, many of the isolated chromaffin cells tended to gather into numerous clusters, from which fine fibrous processes extended. In 2 to 3 weeks, contaminating fibroblasts increased to confluency, while the clustered chromaffin cells built up a complex network of straight fibres interconnecting the clusters. In this micrograph, fibroblastic proliferation was substantially suppressed by treatment with cytosine arabinoside (10 μM) over days 21 and 22 after plating. Scale bar, 100 μm. ***B***, Glyoxylic acid-induced catecholamine fluorescence[14] of the clustered cells after 2 weeks in culture. The same cells can be identified in *C*. In some cases catecholamine-specific fluorescence, though weaker than that of the cell soma, was also detected from neurite extensions (not shown). ***C***, Light micrograph of the field in *B*. Scale bar, 10 μm. ***D***, Electron micrograph of a synaptic structure formed between the cultured chromaffin cells 35 days after plating. Note the synaptic membrane thickening of increased density and the accumulation of small clear vesicles (arrow); a few large dense-core vesicles having an electron-lucent halo around the core (arrowhead) are also present. The specimen was fixed in phosphate buffered 2% glutaraldehyde (*p*H 7.2) followed by buffered 1% osmium tetroxide, dehydrated through graded ethanol, and then embedded in Spurr's epoxy resin[15]. Scale bar, 100 nm. ***E***, Electron micrograph of an intermediate cell type of chromaffin cells cultured for 2 weeks. Small clear vesicles (arrow) and pleomorphic dense-cored vesicles are present. Preparation method similar to *D*. Scale bar, 100 nm.

or subthreshold depolarizing pulses between the test cells, (3) the amplitude of e.p.s.ps varied from one presynaptic stimulus to another, (4) the amplitude of e.p.s.ps was sensitive to the level of postsynaptic membrane potential, increasing with hyperpolarization, and (5) the amplitude of e.p.s.ps increased with an increase in the extracellular Ca^{2+} concentration.

In an attempt to identify the transmitter type responsible for the chemical transmission, we applied several cholinergic and adrenergic blocking agents over the cells that demonstrated synaptic interaction. As shown in Fig. 2, the e.p.s.ps were reversibly affected by (+)tubocurarine (TC), a cholinergic blocker, and also by hexamethonium (data not shown). In contrast, none of these synaptic responses was affected by phentolamine, an α-adrenergic blocker, even at 0.1 mM. The chromaffin cells usually showed spontaneous synaptic potentials after 2 weeks in culture (Fig. 3). The cell illustrated in Fig. 3*A* exhibited spontaneous e.p.s.ps, summation of which gave rise to action potentials. The time course of these responses was similar to that observed in the evoked synaptic responses. These spontaneous e.p.s.ps were also abolished by the cholinergic blocking agent (Fig. 3*B*).

The above data collectively indicate that the adrenal chromaffin cells can develop several neuronal characteristics and form cholinergic synapses between them. This finding raises the possibility that the cultured chromaffin cells may also be plastic with respect to the transmitter choice as reported for the sympathetic ganglion cells, in which the culture environment is known to determine the neurotransmitter selection (see ref. 12 for review). In fact, it has been shown that elevated K^+ concentrations in culture medium prevent the conversion of the superior cervical ganglion cells from an adrenergic to a cholinergic phenotype[13]. When we cultured the chromaffin cells in an NGF-containing high K^+ medium, which was made by diluting Dulbecco's minimal essential medium (DMEM) with 0.2 M KCl

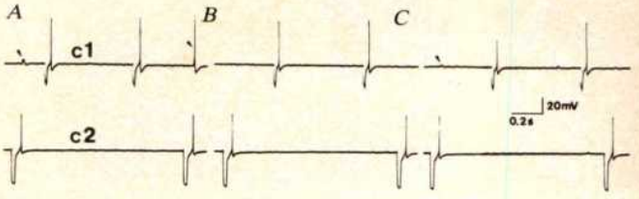

Fig. 2 Intracellular recording of membrane potentials and e.p.s.ps from the chromaffin cells demonstrating chemical synaptic transmission after 32 days culture. Test cells 1 and 2 (c1 and c2), separately chosen from a pair of neighbouring clusters, were stimulated asynchronously by anodal break excitation. Traces *A*, *B* and *C* are all from the same paired cells. For electrophysiological experiments, the culture dish was placed on an inverted phase-microscope stage thermostated at 33–35 °C by circulating water. The test dish was perfused, at about 25 ml h^{-1}, with a prewarmed control solution of Eagle's medium containing 5 mM HEPES (*p*H 7.4). *A*, Anode-break excitation in c2 evoked sub- or suprathreshold e.p.s.p in c1 (arrowheads) with a delay of 3.7 ms; however, firings of c1 had no such effect on c2, indicating that a synapse mechanism was involved. *B*, Perfusion with TC (25 μM) abolished the synaptic response. No change was observed in the anode-break action potentials or in the resting levels of both cells. *C*, After 10 min perfusion with the control solution the cells resumed synaptic activity.

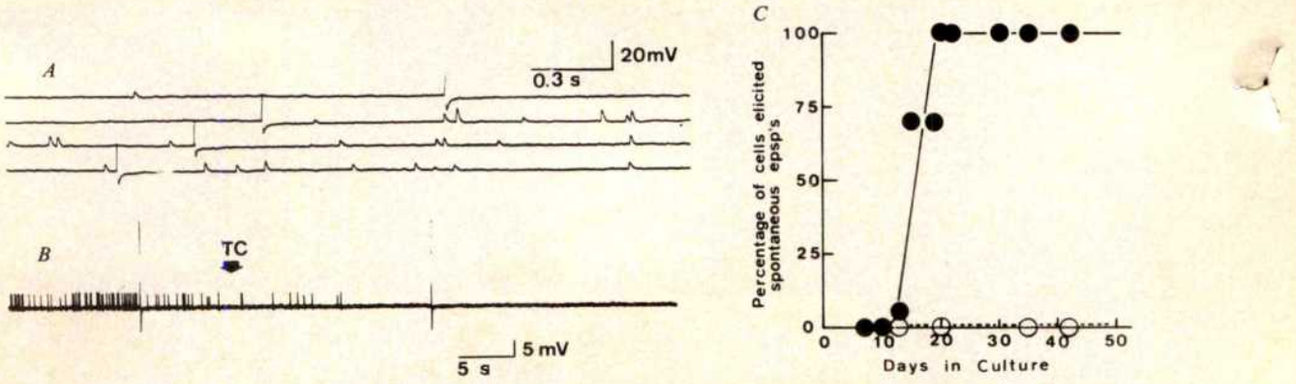
to yield ~20 mM K^+, the cells showed a progressive elongation of processes and formed dense neurite networks such as shown in Fig. 1*A*. Spontaneous or evoked synaptic activity, however, was detected in none of more than 100 cells examined in over 25 culture sets of the high K^+ medium (Fig. 3*C*). On the other hand, the resting potentials of these cells were in the normal range, and the cells were able to produce action potentials



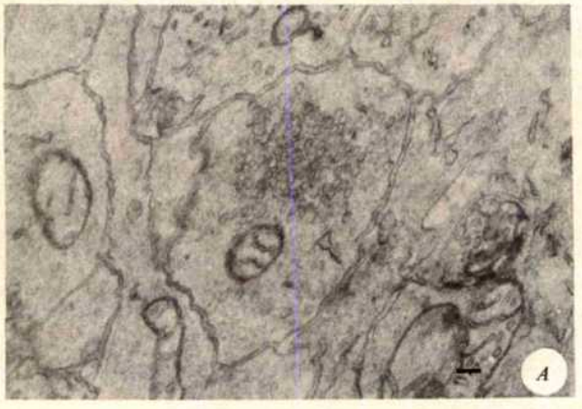


Fig. 3 *A*, Spontaneous synaptic activity recorded from a chromaffin cell cultured for 35 days. All traces are from one continuous record. *B*, Spontaneous e.p.s.ps were also sensitive to TC (25 μM). *C*, Development of spontaneous e.p.s.ps from cells cultured in normal K^+ medium (●) and no such occurrence of e.p.s.ps in high K^+ cultures (○). In each case, 20 cells randomly sampled from 10 different clusters were impaled by a microelectrode with its tip held inside the respective test cells for at least 5 min. Each point represents the percentage of successful detection of spontaneous e.p.s.ps. Test medium was Eagle's minimal essential medium containing 5.3 mM K^+. Test cells were all from the same preparation.

Sister cultures with the normal K^+ medium (DMEM diluted with 0.2 M NaCl instead of 0.2 M KCl) showed the same pattern of synaptic activities as in the control culture. The loss of synaptic activity in the cells cultured in the high K^+ medium is not due to the absence of sensitivity to acetylcholine (ACh), since the responses to ACh iontophoresis (as high as 400 mV nC^{-1}) were indistinguishable from those observed in the control cells. The chromaffin cells, cultured in the high or the normal K^+ medium, were not responsive to adrenaline and noradrenaline.

To determine whether the high K^+ condition modulates the transmitter choice towards the enhanced adrenergic selection, the population of synaptic vesicles was examined ultrastructurally using the $KMnO_4$-fixation procedure, a well known technique to identify the adrenergic vesicles[10,11]. As shown in Fig. 4*B*, most of the synaptic vesicles found in the high K^+ culture were granular, a fact indicative of adrenergic vesicles. In the normal K^+ cultures, however, synapses and varicosities contained over 60% clear vesicles (Fig. 4*A*). Such an observation implies that, in the high K^+ medium, the chromaffin cells may form predominantly adrenergic synapses, and yet the adrenergic synaptic activity failed to be detected electrophysiologically because of a lack of postsynaptic receptors for catecholamines.

Finally, our observation that the adrenal chromaffin cells from neonatal rats can be transformed into neuronal cells equipped with the functional synapses of cholinergic or adrenergic nature depending on the culture condition, supports the view that the precursors of the adrenal and the sympathetic neuronal cells are pluripotential at a certain stage in development and then differentiate into their respective phenotypes under the control of some environmental factors.

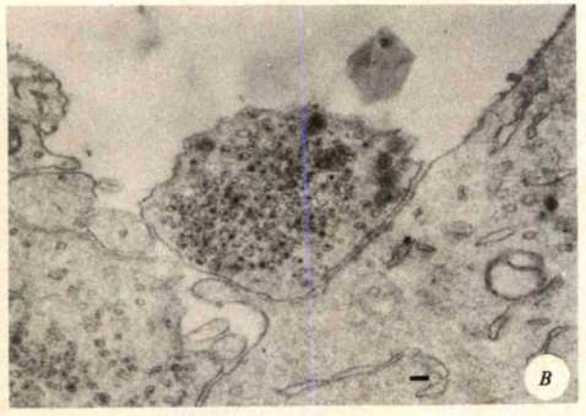

Fig. 4 Electron micrographs ($KMnO_4$ fixation) of synaptic vesicles contained in the chromaffin cells that were cultured with NGF for 30 days in: *A*, normal K^+ medium, and *B*, high K^+ medium. The cells were preincubated for 30 min at 37 °C with 10^{-5} M noradrenaline freshly dissolved in DMEM, washed in Ringer solution, and then fixed in $KMnO_4$ (3%, in Ringer) at 4 °C for 1 h. After washing the cells were stained *en bloc* by uranyl acetate (1%, in 0.1 M nabic acid buffer, *p*H 5.2) at 4 °C for 1–2 h. Dehydration and embedding were processed as in legend to Fig. 1*D*. Scale bar 100 nm.

We thank Professors M. Kuno, G. Pilar and J. Tuttle for helpful discussion and critical reading of the manuscript and Professor A. Inouye for his continual encouragement. This work was supported, in part, by grants 56570032 and 57213028 to M.O. from the Ministry of Education, Science and Culture of Japan.

Slow transmission of neural activity in hippocampal area CA1 in absence of active chemical synapses

A. Konnerth, U. Heinemann & Y. Yaari*

Department of Neurophysiology, Max-Planck-Institut für Psychiatrie, Am Klopferspitz 18A, 8033 Planegg-Martinsried, FRG
* Department of Physiology, Hebrew University Medical School, PO Box 1172, Jerusalem 91010, Israel

Transmission of neural activity in the mammalian cortex involves the operation of chemical synapses[1,2]. Here we report that activity of hippocampal pyramidal cells (HPC) *in vitro* can spread through the neural aggregate even when chemical synaptic transmission is blocked by lowering the external Ca^{2+} concentration ($[Ca^{2+}]_o$). In these conditions focal stimulation of the HPC body layer (stratum pyramidale) at area CA1 evokes a localized repetitive neural response which, when large enough, spreads along this layer in both transverse directions. It was recently reported for similar conditions[3,4] that the activated HPC often discharge in synchrony. However, the spread of the neural response does not depend upon the occurrence of synchronized HPC activity, and therefore represents a distinct phenomenon.

Several lines of evidence suggest that K^+ accumulation in the extracellular space is responsible for the transmission of neural activity through area CA1 in conditions of blocked chemical synapses. (1) The mean velocity of spread was 1.7 mm s^{-1}, which probably is too slow to be mediated by electrical coupling or ephaptic interactions, but is compatible with K^+ redistribution by a spatial buffer mechanism[5]. (2) A rise in $[K^+]_o$ precedes and accompanies the spread of the neural response. (3) Focal applications of K^+ at the CA1 stratum pyramidale can elicit similar neural responses. (4) The spread is accelerated or slowed by increases or decreases in the baseline level of $[K^+]_o$, respectively. Such K^+-mediated transmission of neural activity may have an important role in the spread of epileptiform discharges, which does not necessarily conform to anatomical pathways[6], and which involves synchronous neural firing[7] and large decreases and increases in $[Ca^{2+}]_o$ and $[K^+]_o$[8,9], respectively.

Experiments were performed on 44 rat hippocampal slices, prepared and maintained in a perfused chamber using previously described techniques[10,11]. Changes in $[Ca^{2+}]_o$ and $[K^+]_o$ were monitored with ion-selective microelectrodes (ISM)[8]. Field potentials were recorded with either the reference barrel of the ISM or with single NaCl-filled microelectrodes. Measurements were usually obtained simultaneously from 2–4 adjacent sites (0.02–1 mm apart) in the stratum pyramidale.

To block chemical synaptic transmission, Ca^{2+} was omitted from the physiological solution (in mM: 124 NaCl, 5 KCl, 1.25 $NaHPO_4$, 2 $MgSO_4$, 2 $CaCl_2$, 26 $NaHCO_3$, 10 D-glucose) perfusing the slices. This resulted in a slow decrease of $[Ca^{2+}]_o$ to levels of $1–5 \times 10^{-5}$ M[11]. During the decay of $[Ca^{2+}]_o$, the synaptically evoked responses of CA1 HPC, induced by stimulating the commissural/Schaffer collateral afferent fibres in the stratum radiatum, initially became repetitive and then gradually diminished, until they were totally blocked[11,12]. In these conditions, however, single-shock stimuli applied at the stratum pyramidale (Fig. 1*A*) evoked prolonged (1–5 s), large (1–7 mV) negative potential shifts (NPS) (Fig. 1*B*), which were maximal in amplitude at the stratum pyramidale and smaller when recorded from the dendritic layers (strata radiatum and oriens). Recordings with K^+-selective ISM showed that each NPS is accompanied by a transient increase (1–7 mM above baseline levels) in $[K^+]_o$ (Fig. 2), which was also maximal at the stratum pyramidale. These findings suggest that the NPS reflect the depolarization of neurones and glia induced by K^+ released

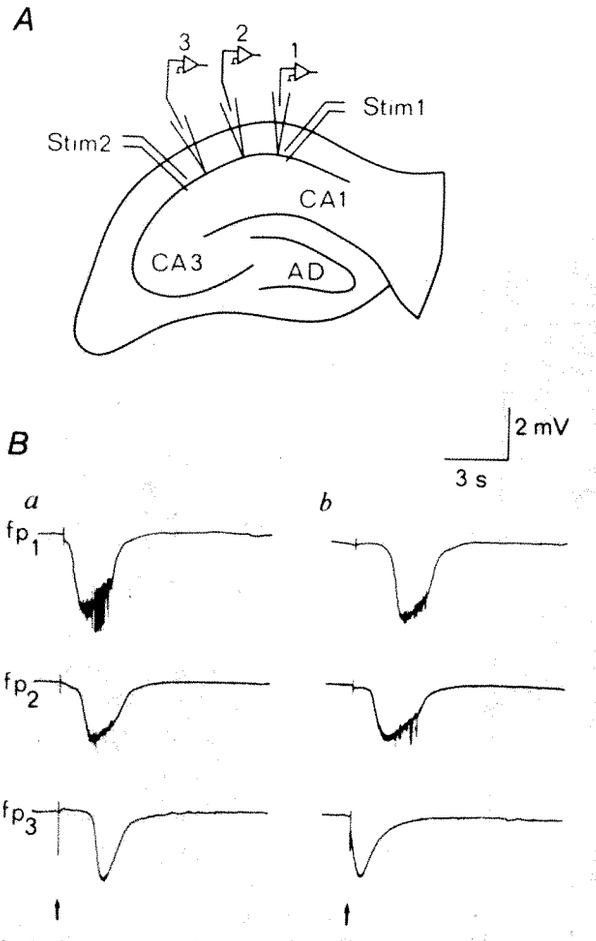

Fig. 1 Transmission of evoked neural activity along hippocampal area CA1 after blocking chemical synaptic transmission by lowering $[Ca^{2+}]_o$. ***A***, The experimental arrangement. Recording microelectrodes (1–3), filled with 100 mM NaCl, were positioned 200 μm apart at the CA1 stratum pyramidale. Stimulating electrodes (Stim1, Stim2) were placed 20–50 μm from the ends of the microelectrode array. AD, area dentata. ***B***, Simultaneous recordings by the three microelectrodes (1–3) of the field potentials (fp_1, fp_2 and fp_3, respectively), evoked in response to single-shock stimuli (70 μs, 40 nA) delivered by Stim1 (*a*) or Stim2 (*b*). Arrows indicate the stimulation artefacts. The responses, composed of a negative potential shift on top of which population spikes can be observed at two recording sites (fp1, fp2), appeared about 25 min after changing from the standard solution to perfusing solution lacking Ca^{2+}. The simultaneous recordings demonstrate an increase in latency of the NPS with the distance between the recording and stimulating sites, thus suggesting a spread of neural activity along the stratum pyramidale.

from activated neurones[3,11,13]. Indeed, extracellular single unit recordings revealed increased firing of HPC during the NPS. Furthermore, at approximately 60% of the slices, the evoked NPS were associated with bursts of population spikes (Fig. 1*B*, upper traces), indicating that during the NPS, the repetitive firing of individual HPC often became synchronized[3,4]. Similar responses were also observed in slices perfused with a 0.2 mM Ca^{2+}-containing solution, in which the synaptically evoked field potentials were also completely blocked. These responses were promptly abolished by reintroducing the standard perfusing solution, whereas the normal synaptically evoked field potentials reappeared. With prolonged (>1 h) perfusion in low-Ca^{2+} solutions, NPS also appeared spontaneously in most of the slices, as has been recently described[3,11].

Once initiated by lowering $[Ca^{2+}]_o$, the responses described above could be evoked by stimulation anywhere along the CA1 stratum pyramidale. When the recording microelectrode was placed near (20–50 μm) the site of stimulation, the response had a brief delay of several milliseconds. This delay increased

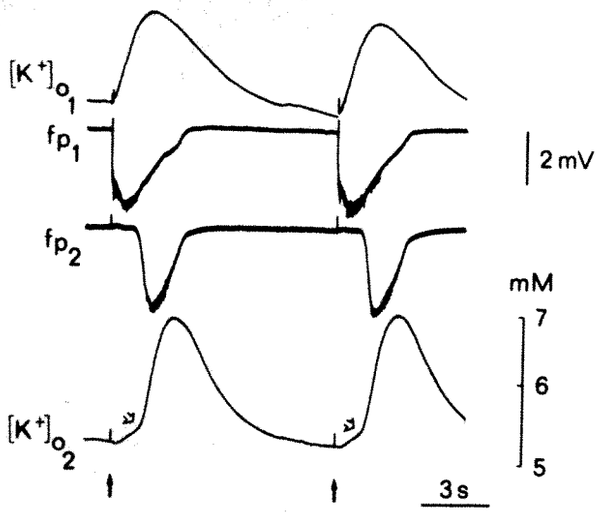

Fig. 2 Changes in $[K^+]_o$ which accompany the spread of neural activity along area CA1, in a slice with blocked chemical synaptic transmission. The experimental arrangement and procedure were basically as described in Fig. 1 legend, except that recording microelectrodes 1 and 2 are double-barrelled K^+-ISM[13], placed 300 μm apart. The K^+-selective barrel was filled with valynomycine exchanger and 100 mM KCl, and had a minimum response of 45 mV to a 10-fold change in $[K^+]_o$; the reference barrel contained 124 mM NaCl. The responses to two consecutive single-shock stimuli (filled arrows indicate stimulus artefacts) delivered by Stim1 are shown. Simultaneous recordings of the field potentials (fp_1, fp_2) and the changes in $[K^+]_o$ ($[K^+]_{o_1}$, $[K^+]_{o_2}$) by ISM 1 and 2, respectively, suggest a spread of neural activity along the stratum pyramidale away from the stimulation site. Note that ISM 1 monitors a monophasic K^+ transient, whereas ISM 2 shows a biphasic increase (transition between the two phases marked by open arrows).

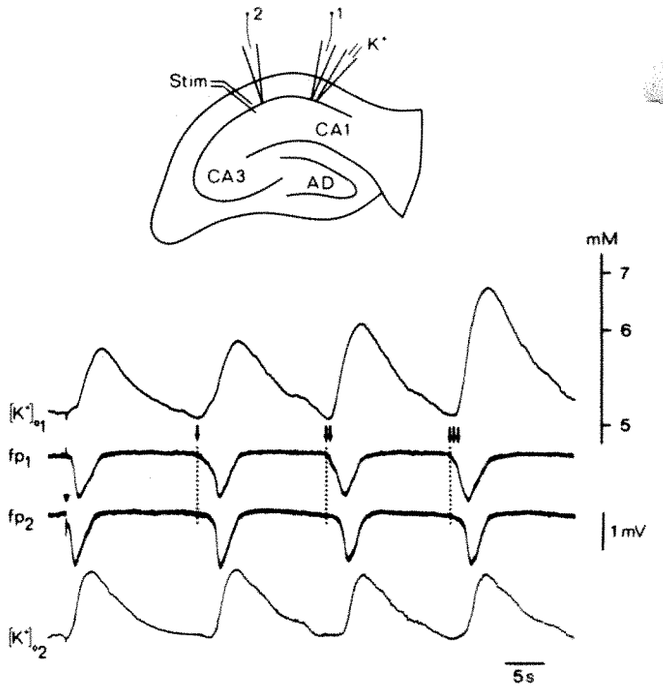

Fig. 3 Spreading NPS evoked at CA1 stratum pyramidale by direct electrical stimulation and K^+ pressure application, in a slice with blocked chemical synaptic transmission. Upper part illustrates experimental arrangement of stimulating electrode (Stim), recording K^+-ISM (1 and 2) and K^+ pressure ejection micropipette (K^+), which were all positioned in the CA1 stratum pyramidale. ISM 1 and 2 were 500 μm apart. The K^+ ejection micropipette, 50 μm from ISM 1, contained 100 mM KCl and had a tip diameter of 1 μm. KCl was applied by pressure pulses of 1 bar and 200 ms. Repetitive KCl pulses were delivered with an interpulse interval of 100 ms. The lower part demonstrates simultaneous recordings of the field potentials (fp_1, fp_2) and the changes in $[K^+]_o$ ($[K^+]_{o_1}$, $[K^+]_{o_2}$) in response to a single-shock stimulation (marked by triangle) and to 1, 2 and 3 pulses of KCl (marked with arrows and dotted lines). Note the spread of the response from its site of initiation towards the distant ISM, and the similarity between the NPS evoked by electrical stimulation and by K^+ application. Similar ejections of NaCl (from a micropipette filled with 100 mM NaCl) were ineffective in eliciting a response.

with the distance between the sites of stimulation and recording. With simultaneous recording from 2–4 separated sites along this layer, the response appeared as a wave of activity, which could be transmitted from the site of stimulation towards either end of area CA1 (Fig. 1*B*). The velocity of this spread varied in different slices from 0.44 to 4.2 mm s^{-1} (1.7 ± 1.21 mm s^{-1}, mean ± s.d., $n = 11$), but in any one slice was the same in both directions. When stimuli were delivered simultaneously at both ends of area CA1 no summation of the response occurred at a recording site in between. Furthermore, several seconds following stimulation at one end of area CA1, a stimulus delivered to the other end was ineffective in eliciting a spreading response. These findings suggest that regardless of its direction of spread, the same neural population participates in the response.

In the absence of normal chemical synaptic function other factors must mediate the spread of neural activity in area CA1. Possible mechanisms are electrical coupling[14,15], ephaptic (electrical field) effects[4,16] and accumulation of K^+ in the extracellular space[11,17,18]. Whether CA1 HPC are electrically coupled is still a matter of controversy[19–21], whereas evidence for the existence of ephaptic interactions has recently been reported[4]. Either of these mechanisms, however, is probably too fast to account simply for our findings. If activity spreads across the densely packed CA1 HPC population from cell to cell, each HPC body being about 20 μm in diameter[22], transmission across two adjacent HPC at a mean velocity of 1.7 mm s^{-1} would require ~24 ms. In contrast, where electrical coupling has been demonstrated in the hippocampus by paired intracellular recordings, transmission of an action potential across two coupled neurones occurs within 1–2 ms[14,15]. Ephaptic interactions among HPC also tend to synchronize their firing within a similarly brief period[4]. Therefore, cell-to-cell transmission of activity via these mechanisms would be expected to spread at a velocity of 20–40 mm s^{-1}, which is at least one order of magnitude higher than what we have observed. It is possible, however, that electrical coupling and ephaptic interactions influence the activated HPC to fire in synchrony, thereby giving rise to the frequently observed population spikes (Fig. 1*B*). These mechanisms have been suggested recently to account for the synchronization of CA1 HPC firing during short afterdischarges[4] or during spontaneous field bursts[3], which occur in solutions with low $[Ca^{2+}]$. Clearly, the fact that the NPS also spread in slices which did not exhibit synchronous population spikes, suggests that synchronization and spread are distinct phenomena, which may differ in their underlying mechanisms.

The observed slow spread of neural activity compares well with the time course of redistribution of $[K^+]_o$ transients through the glial 'spatial buffer' mechanism[5,23,24]. Therefore, an alternative possible mechanism is that K^+ ions, released by active neurones, spread in the extracellular space[13,18,23], and depolarize to threshold neighbouring and perhaps remote quiescent neurones. This action would result in a relatively slow progressive spread of the 'discharge zone'. It has been shown in different preparations that the release of K^+ ions from active neurones can alter the excitability of neighbouring cells[17,25,26], and the fact that HPC CA1 neurones are tightly packed[27] may allow for an effective 'K^+-coupling' mechanism. Indeed, in approximately 80% of our recordings, performed in 27 different slices, the $[K^+]_o$ increases associated with the spreading wave of activity, consisted of two distinct phases (Fig. 2). The first phase was slower and preceded the appearance of the NPS at the recording site; therefore, it may reflect the redistribution of K^+ from an adjacent active zone[24]. The second phase consisted of

a much steeper and larger increase in $[K^+]_0$, and was correlated in time with the appearance of the NPS and the population spikes at the recording site. It is probably due to the local release of K^+ from the bursting neurones nearby. Thus, when the recording ISM was close to the stimulating electrodes, only a monophasic steep increase in $[K^+]_0$ was observed (Fig. 2).

To test the 'K^+-coupling' hypothesis we examined whether similar spreading responses can be elicited by the local release of exogenous K^+. In accordance with this hypothesis, we found that pressure ejection of KCl, but not NaCl, through the tip of a micropipette at the CA1 stratum pyramidale, could elicit typical NPS, similar to the responses evoked by direct electrical stimulation (Fig. 3). These responses also spread from their site of initiation through area CA1 (Fig. 3). Increases in the amount of locally applied K^+ hastened the appearance of the NPS, but did not significantly alter their amplitude (Fig. 3), indicating their all-or-none nature. Accordingly, reducing below a critical level the amount of applied K^+, produced only a local response which did not develop into a full NPS, and did not spread to the remote recording ISM (not shown). As would be predicted from a 'K^+-coupling' mechanism, we also found that elevating the $[K^+]$ in the perfusing solution by 1–2 mM, markedly accelerated the spread of the NPS, whereas lowering it by 1–2 mM had the opposite effect.

In sharp contrast to the responsiveness of CA1 HPC, we were consistently unable to evoke NPS and population spikes by focal stimulation at area CA3 in similar conditions. Furthermore, neural responses evoked at area CA1 always spread towards area CA3, but failed to invade it. A similar difference between the two hippocampal areas has been noted recently in their ability to generate spontaneous NPS in low-Ca^{2+} solutions[3,11]. The reason for these differences is unknown, but it may be relevant that CA1 HPC are more densely packed than CA3 HPC[28], for the efficacy of both K^+-coupling and ephaptic interactions should increase with neuronal density.

The question arises as to whether nonsynaptic transmission of neural activity could occur in the intact brain. At physiological $[Ca^{2+}]_0$, the spread of neural discharge through a cortical structure would be limited by powerful lateral and recurrent inhibitory synaptic mechanisms[2,29]. However, intense cortical activity, observed most dramatically in the hippocampus and neocortex during an epileptic seizure, is accompanied by large decreases in $[Ca^{2+}]_0$ and increases in $[K^+]_0$[8,9,13,30,31]. Indeed, in the baboon neocortex, reduction in $[Ca^{2+}]_0$ to levels below 0.1 mM during an ictal episode have now been found (S. Comtes, U.H., J. Louvel, C. Menini and R. Pumain, in preparation). Such ionic changes are expected to markedly reduce the efficacy of Ca^{2+}-dependent synaptic inhibition[31] and augment HPC membranal excitability[32], thereby facilitating nonsynaptic excitatory interactions among these neurones. The close contiguity of neuronal membranes in hippocampal area CA1[27] would make it a favourable substrate for such interactions, and may explain why seizure discharges in this structure do not seem to spread along anatomical paths by necessity[6], and perhaps why the hippocampus is peculiarly susceptible to epilepsy[33].

Are baclofen-sensitive $GABA_B$ receptors present on primary afferent terminals of the spinal cord?

The site of action of the antispastic drug baclofen has long been considered to reside in the spinal cord[1,2] although supraspinal effects have also been reported[3–6]. This β-chlorophenyl derivative of the neurotransmitter γ-aminobutyric acid (GABA) depresses both monosynaptic and polysynaptic transmission in the cord[7] possibly through a decrease in transmitter release rather than by any antagonism at postsynaptic receptors[7–10]. Recently, baclofen has been shown to be a selective ligand for a bicuculline-insensitive GABA receptor ($GABA_B$) site[11,12] that occurs widely in the mammalian central nervous system including the spinal cord[13]. The apparent importance of the cord in the therapeutic effects of this drug prompted us to ask whether they involve $GABA_B$ site activation. As an initial step we have located these receptors by autoradiography, comparing them with classical $GABA_A$ sites. We report here that $GABA_B$ sites, unlike $GABA_A$ sites, are present in high concentrations in laminae I, II, III and IV of the dorsal horn and that after the neonatal administration of capsaicin this binding is reduced by 40–50%.

The distribution of $GABA_A$ and $GABA_B$ binding sites was determined in 10-μm sections of rat spinal cord. Prepared sections were placed on glass slides and allowed to dry before storage at −20 °C for periods up to 2 weeks. For the binding procedure the sections were thawed, washed and dried prior to incubation with ^{3}H-GABA-containing solution at 20 °C for 20 min. The incubation solution used for detection of $GABA_A$ sites was Tris-HCl buffer solution (50 mM *p*H 7.4) containing 100 μM (±) baclofen. For $GABA_B$ sites Tris-HCl buffer solution was used without baclofen but containing $CaCl_2$ (2.5 mM) and isoguvacine (40 μM) to suppress any binding to $GABA_A$ sites[13,14]. ^{3}H-GABA (50 nM) was used as the receptor ligand

‡ To whom reprint requests should be addressed.

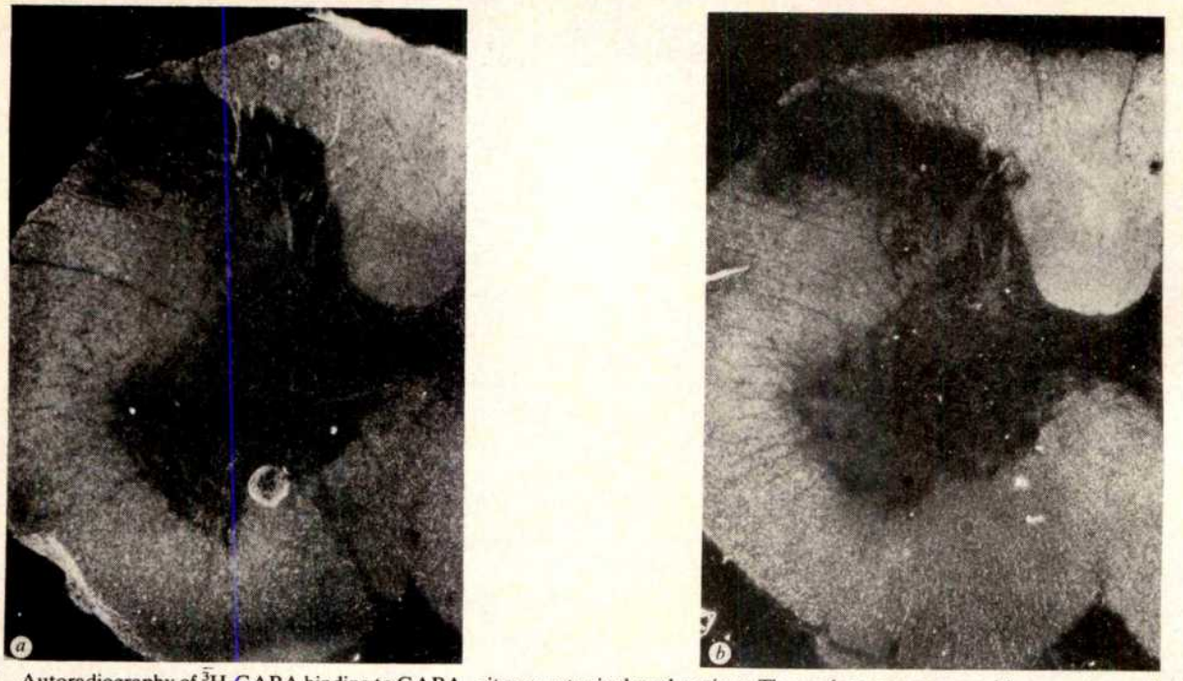

Fig. 1 Autoradiography of ^{3}H-GABA binding to $GABA_A$ sites on rat spinal cord sections. The sections were prepared from a rat anaesthetized with pentobarbitone before intracardiac perfusion with 200 ml 0.1% paraformaldehyde in 0.01 M phosphate-buffered saline (*p*H 7.4). A segment of cervical cord was removed and immersed in isopentane in liquid nitrogen. Transverse sections (10 μm) were mounted on glass slides and allowed to dry at ambient temperature for 1 h before storing at −20 °C. For the binding procedure the sections were allowed to thaw and dry for 45 min before immersion in Tris-HCl solution (50 mM *p*H 7.4) containing sucrose (190 mM) for 60 min. After this the sections were dried before covering with 100 μl of the Tris solution containing ^{3}H-GABA (60 Ci mmol^{-1}, 50 nM) and (±)baclofen (100 μM) without (*a*, total binding) or with (*b*, nonspecific binding) unlabelled isoguvacine (100 μM). This was left in contact for 20 min after which the solution was aspirated off and the sections briefly rinsed twice in large volumes of Tris solution. The sections were allowed to dry and coverslips previously dipped in Ilford K5 emulsion (emulsion:water 1:1.5) were attached to the slides with Loctite glue and placed in a light-tight box containing silica-gel for 16 days at +4 °C. The emulsion was developed at 16 °C in Kodak D19 developer (3 min) and fixed in 25% sodium thiosulphate solution. After several washes the slides were dried overnight and the coverslips fixed permanently in position with DPX mounting medium. Sections were viewed under dark-field optics with a Reichart Polywar microscope. Note in *a* the even density of grains throughout the grey matter indicating the presence of $GABA_A$ sites in all laminae.

throughout these studies and was therefore present in both incubation solutions at the same concentration. After incubation, the sections were briefly rinsed twice before being air dried. The distribution of ^{3}H-GABA binding sites was then investigated using the dry-mounting autoradiographic technique previously described[13,15]. Each slide was placed in close apposition to a coverslip coated with Ilford K5 photographic emulsion for 14–21 days. After developing, the grains per unit area were counted under dark-field optics. To facilitate comparison between the distributions of $GABA_A$ and $GABA_B$ sites, adjacent sections from the same cord were routinely incubated in appropriate conditions.

$GABA_A$-binding sites were evenly distributed throughout the grey matter of the spinal cord (Fig. 1), although there were slightly more in the dorsal horn than in the ventral regions. In contrast, the distribution of $GABA_B$-binding sites was not uniform (Fig. 2). Although $GABA_B$ sites could be detected throughout the grey matter, a clear band of high grain density was evident in the dorsal horn. This band was located mainly in laminae II and III (Fig. 2) but considerable numbers of grains were also evident in laminae I and IV and in the dorsal aspects of lamina X around the central canal.

A comparative analysis of the laminae grain densities indicated that there were more $GABA_B$ sites in the dorsal laminae than in the ventral laminae whereas $GABA_A$ sites showed very little fluctuation (Fig. 3).

Many studies of peripheral and central nervous tissue show that $GABA_B$ sites can occur presynaptically[11,16–21] although a

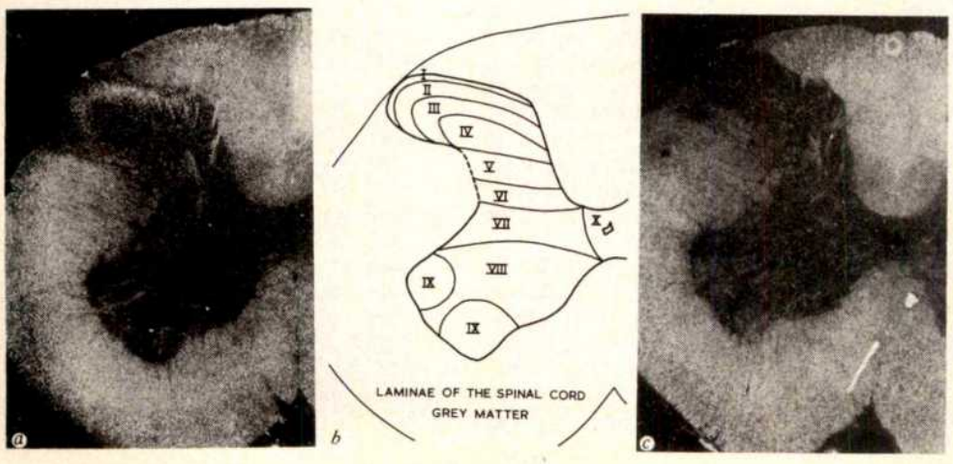

Fig. 2 Autoradiography of ^{3}H-GABA binding to $GABA_B$ sites in rat spinal cord. Sections of spinal cord were prepared and treated as described for Fig. 1 except that the washing and incubating solutions contained 2.5 mM $CaCl_2$ and the incubating solutions contained 40 μM isoguvacine. $CaCl_2$ facilitates binding to $GABA_B$ sites while isoguvacine suppresses all binding to $GABA_A$ sites[12]. (±)Baclofen (100 μM) was absent in *a* but present in *c* to obtain the background (non-specific) binding. *b*, Diagram of the separation between the laminae. In *a* grains corresponding to $GABA_B$ sites appear right across the grey matter but the distribution is uneven. A dense band of grains is apparent in laminae II and III.

Table 1 Distribution of $GABA_B$ sites in the dorsal horn of the rat spinal cord after neonatal administration of capsaicin

Lamina	Control (specific grains per 1,000 μm^2)	Capsaicin-treated	% Reduction
I	49.7 ± 5.4	29.8 ± 3.6	40.0
II_{outer}	60.2 ± 5.6	32.6 ± 3.1	45.8
II_{inner}	64.7 ± 6.2	32.8 ± 5.0	49.3
III	57.0 ± 8.6	26.8 ± 2.2	53.0
IV	40.7 ± 8.0	24.7 ± 2.6	39.3

Mean values ± s.e.m. Data obtained from average density in each lamina of six sections from capsaicin-treated animals and control littermates injected with vehicle alone.

postsynaptic location is possible[22]. The question arises therefore are $GABA_B$ sites in the dorsal horn pre- or postsynaptic to the afferent fibre inputs? In all systems so far studied which show a presynaptic location, the activation of $GABA_B$ sites reduces the evoked release of neurotransmitter. Such an action on terminals in the dorsal horn might well explain how baclofen acts as an analgesic[23–25] and suppresses at least part of the symptoms of morphine withdrawal[26–28].

Autoradiographic studies at the light microscope level in normal tissue cannot distinguish between pre- and postsynaptic locations. However, by selective elimination of the neural components, a distinction might become evident. It has been shown, for example, that after dorsal rhizotomy, opiate receptor binding decreases by 40% whilst leaving the binding of ^3H-neurotensin intact[29]. It is, therefore, unlikely that neurotensin binding sites are located presynaptically whereas there may be a population of opiate sites on the afferent terminal. Of course, this latter conclusion discounts any possible postsynaptic changes which may arise from presynaptic degeneration. Nevertheless, we have used this approach in an attempt to locate the $GABA_B$ site. Selective degeneration of sensory afferent fibres was produced by the neonatal administration of capsaicin[30] following the procedure adopted by Faulkner and Growcott[31]. Three to four months after injection, transverse sections of cord were prepared. Sections were also prepared from littermates injected with vehicle alone. The binding of ^3H-GABA was then performed as described above and the distribution of binding sites determined by autoradiography (Table 1). Capsaicin treatment reduced the number of $GABA_B$ binding sites in substantia gelatinosa by 40–50% when compared with control littermates. Immunocytochemical analysis of the sections for the presence of substance P by the peroxidase–anti-peroxidase (PAP) technique[32] indicated that the capsaicin treatment had produced a marked reduction in the peptide content of the gelatinosa when compared with littermates injected with vehicle alone. Similarly, a reduction in the fluoride-resistant acid phosphatase (FRAP) activity[33] was also noted. Both of these systems are considered to be markers for primary afferent terminals[34,35]. Thus, taken together, these data confirm that at least some of the $GABA_B$ sites detected in sections of normal spinal cord are present on primary afferent terminals. Whether the remaining sites are located presynaptically on descending pathways or on postsynaptic elements remains unclear.

The distribution of $GABA_B$ sites in the cord corresponds closely with that of the GABA-synthesizing enzyme, glutamic acid decarboxylase (GAD), a marker for GABA-containing synaptic terminals[36,37]. The location of this enzyme in the dorsal horn agrees with a presynaptic function for GABA[36,37]. Thus it is possible that the GABA released at these axo-axonic contacts is impinging on $GABA_B$ receptors. Alternatively, as pointed out by Palacios *et al.*[38], bicuculline-sensitive $GABA_A$ receptors may receive this innervation. These authors have described the location of ^3H-muscimol-binding sites in spinal cord incubated in conditions which would facilitate binding to $GABA_A$ sites, but only a low concentration of sites could be discerned. Singer and Placheta[39], using membrane pellets prepared from rat dorsal horn, have shown that neonatal capsaicin treatment can reduce the number of ^3H-muscimol-binding sites

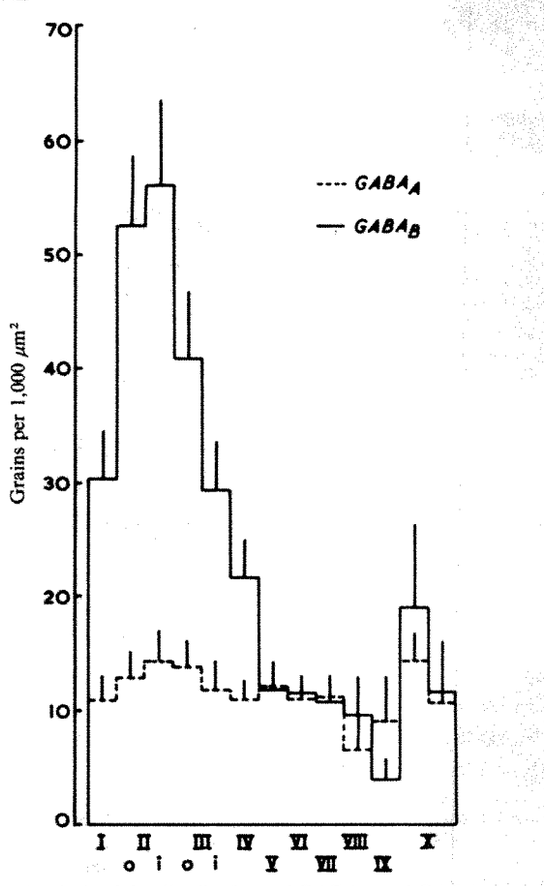

Fig. 3 Analysis of the distributions of $GABA_A$ and $GABA_B$ sites in rat spinal cord sections. Transverse sections of spinal cord were prepared and incubated with ^3H-GABA for $GABA_A$ or $GABA_B$ site detection as described in the legends to Figs 1 and 2. Autoradiograms were subsequently prepared as described in Fig. 1. Grain densities in the individual laminae were determined by counting three areas in each lamina or lamina region (inner, i; or outer, o) from the spinal cords of six rats. Measurements were made after ascertaining that grain accumulation was linear with time. Mean values ± s.e.m. (vertical lines) are shown. The solid outline represents $GABA_B$ site concentrations whereas the broken outline represents $GABA_A$ site concentrations.

by 20–30%. This would support the long-established view that bicuculline-sensitive GABA receptors ($GABA_A$ sites) are present on primary afferent terminals. However, since the concentration of $GABA_B$ sites is much higher they may have a greater role in GABA-mediated axo-axonic transmission in the spinal cord.

G.W.P. is a SERC-CASE award recipient in collaboration with ICI Pharmaceuticals Division. Financial support from the MRC is gratefully acknowledged. We thank Dr M. Hanley and Dr F. Schon for performing the substance P and FRAP analyses respectively, Dr P. Krogsgaard-Larsen for supplies of isoguvacine, CIBA-Geigy Ltd for (±)baclofen, and Mrs J. Andrews for typing the manuscript.

Haemoglobin (Hb) is the tetrameric protein molecule that in vertebrate blood transports oxygen from the lungs to the tissues. This function depends on four subunits in the molecule binding cooperatively so that their affinity for oxygen increases as the level of oxygenation increases. X-ray analysis has shown that deoxyhaemoglobin, which has a low oxygen affinity, and oxyhaemoglobin, which has a high oxygen affinity, differ principally in their subunit or quaternary structures[1], referred to as the T and R states, respectively. As it switches from the T state to the R state during oxygenation, Hb increases its oxygen affinity. However, the structural pathway between deoxy- and oxyhaemoglobin is not known, principally because there has been no accurate structural knowledge of the intermediate states. We report here the crystal structure of T state human Hb in which the α chains are oxygenated and the β subunits are oxygen-free. In this crystal the Hb appears to be in an intermediate state between the unliganded T state and the liganded R state. There is also evidence that the Hb molecule operates by loading and unloading the β haems and thus the α-oxy,β-deoxy Hb crystal may represent a physiologically important state[2].

Perutz has proposed[3] that oxygen's binding to Fe(II) in deoxyhaemoglobin alters the stereochemistry at the haem which destabilizes the T state quaternary structure, favouring its switch to the R state quaternary organization with its higher oxygen affinity. The crystal structures of deoxyhaemoglobin[4] and oxyhaemoglobin[5] have been determined with considerable accuracy and consequently there is a detailed atomic description for these two structures[6]. The partially oxygenated T-state Hb crystal has parallels with the crystalline intermediate produced by Anderson[7] and agrees with the α subunits in the T structure having the higher oxygen affinity because the binding of oxygen to the β haems is hindered by $(CH_3)_\gamma$ of the distal valine[3,8]. The crystals were grown from polyethylene glycol (PEG), following the procedure of Ward and his colleagues[9], except that air was allowed entry into the crystallization vessels and the crystals were transferred to more concentrated solutions of PEG before X-ray study[10]. A number of crystal forms were produced with these conditions which were identifiable from their X-ray diffraction patterns[11]. They are all similar to the crystal form reported by Ward *et al.*[9], containing one complete molecule in the asymmetric unit. Preliminary studies at 3.5 Å resolution on two of the more reproducible forms showed that one was apparently unliganded while the other appeared to contain liganded α haems (unpublished work).

Table 1 Stereochemical features of the haem in various molecules

Molecule	Fe–O (Å)	Fe–Ô–O (°)	O–O (Å)	Fe–Nε (His F8) (Å)	(Å)	Fe–Ct
T state Hb(PEG)						
α_1-oxy	1.81	160 ± 5	1.23	2.23†	2.10§	0.2*
α_2-oxy	1.81	160 ± 5	1.24	2.50†	2.39§	0.2*
β_1-deoxy	—	—		2.21†	2.39§	0.3*
β_2-deoxy	—	—		2.20†	2.14§	0.3*
T state Hb[5]						
α-deoxy				2.00‡		0.60
β-deoxy						
R state Hb[4]						
α-oxy	1.67	153	1.22	1.94	1.94	0.13
β-oxy	1.83	158	1.24	2.06	2.06	0.08
Mb[14]						
deoxy	—	—	—	2.22	2.22	0.42
oxy	1.83	115	1.18	2.07	2.07	0.18

Fe–Ct, the distance from the haem plane to the Fe(II).
* The haem plane is defined by the least squares plane through the four pyrrole nitrogens.
† These values (e.s.d. 0.1–0.2 Å) were obtained after six cycles of refinement with Fe–Nε restraints removed. The Fe–Nε distance in the initial set of coordinates lay between 2.08–2.11 Å, essentially the distance to which it had been restrained.
‡ Diamond refinement at 2.5 Å (ref. 5).
§ Refinement values obtained with the Jack–Levitt procedure[15]; weak restraints were applied to the Fe–Nε distance.

A 2.1 Å dataset was subsequently collected at Laboratoire pour l'Utilisation de Rayonments Electromagnetique (LURE) on a partially liganded crystal. The crystal structure was refined from the human deoxyhaemoglobin coordinates[6], positioned correctly in the PEG Hb cell by molecular replacement calculations[11]. The initial agreement factor $R(=\sum||F_o|-|F_c||/\sum|F_o|)$ was 0.52; on refinement, this has been reduced to 0.21.

The refinement of the crystal structure was carried out using the fast Fourier least squares procedure of Agarwal[12]. At a resolution of 2.1 Å the calculated shifts are inaccurate and the correct peptide geometry was imposed[13] on the atomic coordinates after each shift calculation.

Refinement of the well-ordered atoms is essentially complete with the estimated error in their atomic positions being between 0.1 and 0.2 Å. The further lengthy crystallographic refinement needed on some of the poorly ordered residues, and in improveing and extending the descriptions of the solvent structure, will be published elsewhere. It will not alter materially the picture we have of the stereochemical features at the haem groups presented here.

The bond distances and angles at the Fe(II) which are most liable to be affected by ligation unfortunately presented a particular difficulty since they are not known with the same accuracy as those in peptides. The effect of different restraints of geometries on the refinement of the groups about the haem was explored. A parallel refinement was also carried out with the Jack-Levitt procedure which was used in the oxyhaemoglobin study[15]. The coordinate sets finally arrived at agreed satisfactorily within their standard deviations, the well-defined atoms in the haems differing by less than 0.18 Å. There is nonetheless evidence from the refinement calculations and from the electron density (Figs 1 and 2 and Table 1) that the Fe–Nε (His F8) distance in the α_2 subunit is rather longer than the normal values, which raises the possibility that the Fe is in the high-spin state.

The electron density at the α haems and the β haems is illustrated in Figs 1 and 2. The oxygen peak is well defined and

Fig. 1 Stereo view of the electron density at and surrounding the α haems calculated with $2F_o - F_c$ coefficients and excluding the haem and proximal and distal histidines from the phasing. The atoms in the haems and proximal and distal histidines are shown: *a*, $\alpha 1$; *b*, $\alpha 2$.

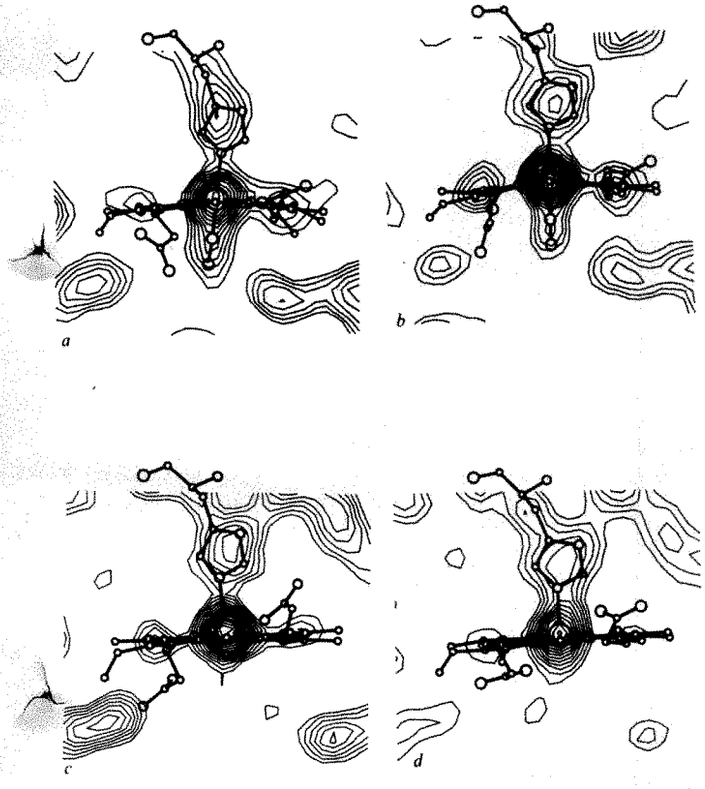

Fig. 2 The haem and proximal histidine viewed edge-on. A section of the electron density, calculated as for Fig. 1, through the Fe and proximal histidine (and oxygen in the case of the α haems) is shown *a*, $\alpha 1$; *b*, $\alpha 2$; *c*, $\beta 1$; *d*, $\beta 2$.

its height suggests that it is fully occupied in the crystal. Calculations on the oxygen's occupancy confirm this.

Two notable features in the partially oxygenated molecule are, first, that the arrival of the oxygens at the α haems has produced only limited movement from the T state. Second, there is a marked folding of the haems in both α subunits. (Refinement of high salt deoxyhaemoglobin at 1.7 Å (G. Fermi, personal communication) and PEG deoxyhaemoglobin at 2.1 Å (unpublished results) reveals that the α haems in these molecules are buckled in an identical fashion to that observed in the partially oxygenated form.) This stereochemistry lifts the Fe(II) about 0.2 Å out of the plane defined by the four pyrrol nitrogens; note that the Fe(II) is at, or very near to, the apex of the pyramid formed by the planes of the four pyrrole rings. In contrast, the β haems are essentially flat and the 5 coordinate Fe(II) is about 0.3 Å out of the plane (Fig. 2).

This indicates that the globin is restraining the haem and the oxygen from assuming a more favourable stereochemistry, thereby reducing the stability of the T state relative to the R state. The particularly close interaction between the haemoglobin molecules in these crystals undoubtedly serves to stabilize the T state quaternary structure and is evidently preventing the switch to the R state and inhibiting further ligation of the β haems.

Detailed analysis of the structural changes associated with oxygen's binding can only be made when the fully deoxygenated molecule's crystal structure is refined and can be compared to the liganded molecule. Then the significance of the Fe–Nε distances and of the different oxygen interactions in the two α subunits can be better assessed. Comparison is being extended to the structures of the deoxy Hb and the fully liganded T state Hb aquomet and azide species. In this way we hope to elucidate how the steric effects in the Fe coordination and in the haem's geometry lead to the structural movements in the globin that destabilize the T state, thus favouring the R state and generating increased oxygen affinity.

We thank Drs Roger Fourme, Philip Evans, Simon Phillips, Boaz Shaanan and Max Perutz for help and support, Dr Yves Mauguen for data collection and LURE for facilities. Ferrara β^0 thalassaemia caused by the β^{39} nonsense mutation

Mario Pirastu*, Laura del Senno†, Francesco Conconi†, Calogero Vullo‡ & Yuet Wai Kan*

Ferrara type of β^0 thalassaemia has two unusual features: first, normal β-globin chain synthesis is inducible either in cell-free systems prepared from patients' reticulocytes by adding supernatant factors from non-thalassaemic reticulocyte lysates[1] or in heterologous cell-free translation of thalassaemic mRNA[2]; second, β-globin synthesis is inducible in patients *in vivo* after blood transfusion[3,4]. We now describe a molecular lesion of the β-globin gene that is common to nine cases of Ferrara β^0 thalassaemia but cannot be reconciled with the inducible response.

DNA from nine patients with this disorder was analysed by the synthetic deoxyoligonucleotide method[5,6]. Two nonadecamers were used as hybridization probes, one homologous to the normal β-globin gene sequences at the region corresponding to β^{39}, and the other to the same region of a β^0-thalassaemia gene caused by a β^{39} (Gln, CAG→TAG) nonsense mutation[7]. In well-defined hybridization and washing conditions, each probe hybridizes only to its homologous sequence. The DNA sequences from 17 chromosomes of the nine patients hybridized with the β^0-thalassaemia probe (Fig. 1), indicating that the primary lesion responsible for Ferrara β^0 thalassaemia is the β^{39} nonsense mutation. The nature of the mutation in the remaining chromosome has not been defined. The β^{39} nonsense mutation is widespread throughout the Mediterranean region. It has been detected in other parts of Italy, Greece, Turkey, Morocco, Lebanon and Spain (M.P. and Y.W.K., unpublished data).

We cannot reconcile our present findings with the previously reported results. One possible explanation for the *in vitro* induction of β-globin synthesis is that suppressor tRNA was present in the supernatant factors used. It has been demonstrated previously that the amber termination codon in β^0 thalassaemia can be suppressed with an amber suppressor tRNA[8–10]. However, although a tRNA with a UGA suppressor has been described in rabbit reticulocytes[11], no amber suppressor has yet been detected in humans. Furthermore, the suppressor tRNA theory cannot explain the *in vivo* transfusion results. We have examined transfusion records of 100 Sardinian β^0 thalassaemia patients with the same β^{39} nonsense mutation and did not observe induction of β-globin synthesis at any time following transfusion. The Ferrara patients should be reinvestigated in light of the present findings.

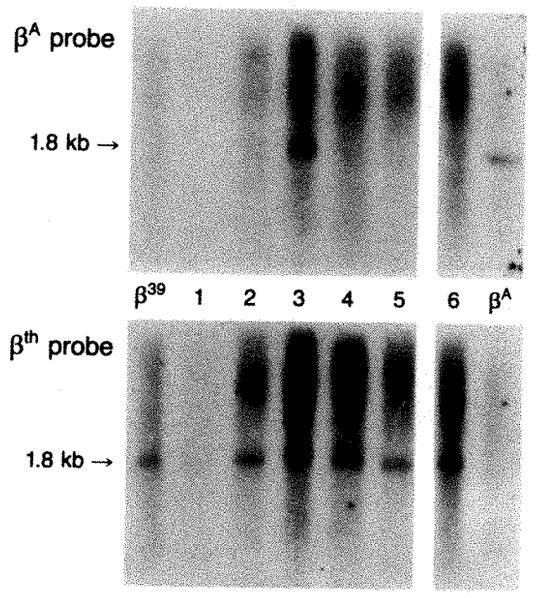

Fig. 1 Autoradiographs of gels containing DNA from Ferrara patients, hybridized with synthetic deoxyoligonucleotide probes. The method used has been described in detail[7]. Briefly, DNA was digested with *Bam*HI, electrophoresed on agarose gels, and hybridized with two ^{32}P-labelled nonadecamer probes. The β^A probe has the sequence 5′ CCTTGGACCCAGAGGTTCT 3′ and is homologous to the coding strand of the normal β-globin gene at the position corresponding to amino acid numbers 35–42. The β^{th} probe has the sequence 5′ AGAACCTCTAGGTCCAAGG 3′ and is homologous to the noncoding strand of the β-thalassaemia gene with the β^{39} (Gln, CAG→TAG) nonsense mutation at the same amino acid position. Results of samples obtained from six of the nine Ferrara β^0 thalassaemia patients (1–6) are compared with DNA from a Sardinian with the same β^{39} nonsense mutation (β^{39}) and with DNA from a non-thalassaemic individual (β^A). Patient 3 is the only double heterozygote for the β^{39} nonsense mutation and another undefined β-thalassaemia lesion. All other patients were homozygous for the β^{39} nonsense mutation.

Most κ immunoglobulin mRNA in human lymphocytes is homologous to a small family of germ-line V genes

David L. Bentley

Fred Hutchinson Cancer Research Center, 1124 Columbia Street, Seattle, Washington 98104, USA

The mammalian immune system produces 10^6–10^8 different antibody-combining sites[1]. It has been established that three factors contribute to the diversity of immunoglobulin variable regions: multiple gene segments in the germ line, somatic recombination of these segments and somatic mutation[2]. However, the relative importance of these components in generating the antibody repertoire is unknown. One way to assess the importance of the germ-line component relative to the somatic components would be to determine the number of germ-line *V* genes expressed. Here, I report that a family of about 25 human germ-line *V* genes encodes over 50% of κ mRNA in spleen or peripheral blood lymphocytes. This observation agrees with gene-counting experiments which indicated that the total number of V_κ genes in the human genome is quite small, about 50 or less[3]. Such a small number of germ-line V_κ sequences implies that somatic mutation is the major source of human κ-chain diversity.

κ-Chains constitute about two-thirds of light chains in human serum[4]. Over 180 peptide sequences of human κ variable (*V*) regions have been determined and can be placed into four subgroups (V_κ1–4)[5,6]. The present study investigated the expression of V_κ genes by hybridization of cloned human genes to lymphocyte mRNA. A constant region (C_κ) probe will hybridize to all κ mRNAs while a V_κ probe will only detect the subset of mRNAs encoded by genes which cross-hybridize with that particular sequence. Thus, the amount of hybridization of a V_κ probe relative to a C_κ probe corresponds to the fraction of mRNA encoded by a given set of cross-hybridizing V_κ genes[7]. The number of homologous genes in the germ line can be estimated from hybridization of the V_κ probe to genomic DNA. In this way, it is possible to quantitate the contribution of a given number of germ-line V_κ genes to the pool of κ light chains expressed by an individual.

Two cloned human V_κ genes from subgroups 1 and 3 were used as hybridization probes. The DNA sequences of these genes are shown in Fig. 1. The V_κ1 sequence is from an unrearranged gene, *HK101*, isolated from fetal liver DNA[8]. The V_κ3 sequence is from two overlapping cDNA clones made from the NG9/9.1 hybridoma which is the fusion product of a mouse plasmacytoma and a human spleen cell[9]. The NG9 V region is one amino acid longer than the HK101 V region. The two sequences show 61% amino acid homology and 72% nucleotide homology. In the framework coding regions, the DNA sequences are 77% homologous and in complementarity determining regions they are 63% homologous.

The spectrum of V_κ genes that cross-hybridizes with each of these two cloned genes in a genomic Southern blot is shown in Fig. 2*a*. It is clear that most of the hybridizing restriction fragments are detected by both the V_κ1 and V_κ3 probes, confirming a previous experiment with other probes[3]. This family of genes is also likely to contain V_κ4 sequences which are more closely related to V_κ1 and V_κ3 than these two are to one another. The group of restriction fragments identified by the V_κ1 and V_κ3 sequences contains about 25 V_κ genes including at least one pseudogene[8]. This number is based on several lines of evidence, including counting hybridization bands in Southern blots[3], exhaustive cloning and sequencing of V_κ genes from one band[10], probe excess solution hybridization[11] and counting the frequency of hybridizing clones in a phage λ library[11]. The expression of these V_κ genes was analysed by hybridization of the same two probes to lymphocyte mRNA.

Initially κ-chain sequences in spleen poly(A)$^+$ RNA were characterized by Northern blot hybridization to C_κ- and V_κ1-specific restriction fragments. In both cases a doublet about 1,100 bases long was seen (Fig. 2*b*). A similar result was obtained when total spleen RNA was analysed (data not shown). The size of the hybridizing RNA is that expected for κ mRNA and it shows that genuine mRNAs from rearranged *V* and *C* genes and not abberrant transcripts are being observed. Densitometry of the Northern blot autoradiogram showed that the intensity of the signal with the V_κ1 probe was 75% of that with the C_κ probe, implying that a substantial proportion of κ mRNAs hybridize with this variable region sequence.

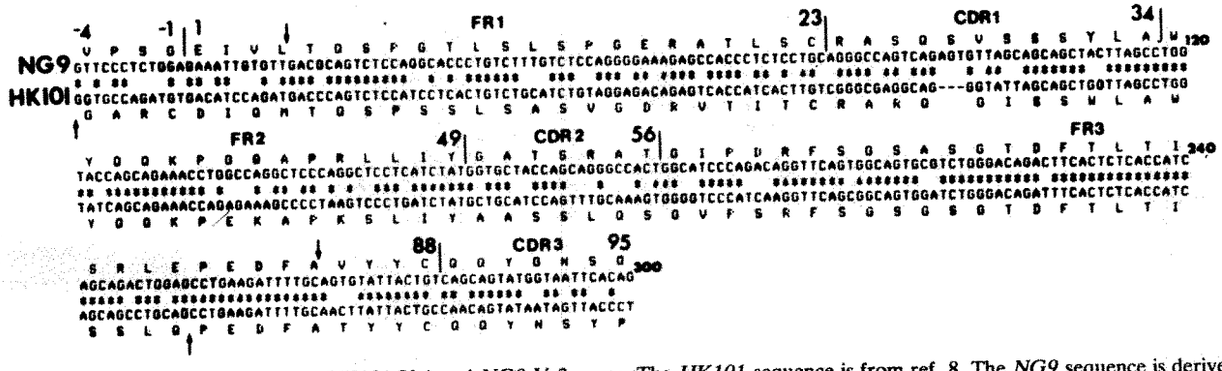

Fig. 1 DNA sequence comparison of *HK101* V_κ1 and *NG9* V_κ3 genes. The *HK101* sequence is from ref. 8. The *NG9* sequence is derived from two cDNA clones that extend from codon 59 into the *J* region (*NG9*/V_κ3)[3] and from codon 4 to codon 84 (*NG9*/3). The amino acid translation is given in one-letter code and the numbering is according to ref. 5. The *NG9* sequence confirms the positions of N-terminal leucine residues reported in ref. 9. The framework (FR) and complementarity determining regions (CDR) are indicated. The *NG9* *V* region has an extra residue at position 27A relative to the *HK101*/*V* region. Nucleotide identity is shown with asterisks. Arrows mark the ends of fragments used to probe spleen RNA.

Methods: Construction and sequencing of the *NG9*/3 cDNA clone. cDNA synthesis was primed on 2 μg of poly(A)$^+$ RNA (a gift of C. Milstein) with 0.5 ng of a ^{32}P-labelled single-stranded 123-base fragment from the 5′ end of the *C* region. The synthesis of the primer was by the method used for preparation of prime-cut probes described in Fig. 3 legend. Primer was annealed to RNA in 20 mM PIPES *p*H 6.4, 1 mM EDTA, 0.5 M KCl in a 15-μl reaction for 6 h at 58 °C. The annealing reaction was diluted 10-fold into a reverse transcriptase reaction and incubated at 42 °C for 1 h. Full-length cDNA was isolated from a denaturing gel and used for second strand synthesis by the Klenow fragment of polymerase I. The hairpin was cleaved with S_1 nuclease. The ends were repaired with T4 DNA polymerase and then blunt-end ligated into the *Hin*dII site of mp7. The *NG9*/3 clone was selected by *in situ* plaque hybridization with the *NG9*/V_κ3 insert. The *NG9*/3 insert was obtained in both orientations in M13 vectors and was completely sequenced on both strands by the chain termination method[22].

For more rigorous quantitative analysis, total RNA from spleen or peripheral blood lymphocytes was hybridized in solution to saturation with an excess of a single-stranded, uniformly ^{32}P-labelled restriction fragment containing $V_\kappa 1$, $V_\kappa 3$ or C_κ sequences. RNA–DNA hybrids were detected by resistance to the single-strand-specific exonuclease VII (exoVII). An exonuclease was chosen to preserve hybrids with internal mismatches. The endonuclease S_1 reduced the yield of full-length resistant hybrids with the V_κ probes by fourfold relative to exoVII. The restriction fragment probes had irrelevant vector or intron sequences at the ends, so the shorter nuclease-resistant RNA–DNA hybrids could be resolved on a gel. Figure 3 shows an example of the results. Arrows indicate the exoVII-resistant fragments corresponding to full-length protection of the immunoglobulin-coding sequences. The results of several experiments with RNA from two spleens are summarized in Table 1. The data were quantitated by counting the radioactivity in bands excised from gels. After correcting for the different numbers of ^{32}P-labelled nucleotides in the nuclease-resistant fragments, the relative amounts of hybridization of the V_κ and C_κ probes was calculated. In both spleens over 20% of κ mRNA was detected by each of the two V_κ probes.

It was important to establish whether or not the $V_\kappa 1$ and $V_\kappa 3$ genes cross-hybridize with the same mRNAs in the nuclease-resistance assay. In a control experiment, the *HK101* $V_\kappa 1$ sequence did not form an exoVII-resistant hybrid with $V_\kappa 3$ mRNA from the NG9 hybridoma (data not shown), showing that these two V_κ probes cannot cross-react with identical subsets of the κ mRNA population. When a mixture of the two probes ($V1+3$) was hybridized to RNA in a 5:1 DNA:RNA molar ratio of each, the amount of hybridization equalled the sum of that observed with each probe alone in a 10:1 molar ratio ($V1+V3$; see Fig. 3, Table 1). This result shows that the hybridizations proceeded to completion and that the two cloned V_κ genes react with completely non-overlapping subsets of κ mRNA. These experiments contrast with filter hybridizations in which $V_\kappa 1$ and $V_\kappa 3$ sequences readily cross-react. The reasons for the greater specificity of the RNA–DNA solution hybridization experiments are that the hybrids are formed in more stringent conditions and then subjected to nuclease digestion. It is most likely the $V_\kappa 1$ and $V_\kappa 3$ genes only form exoVII-resistant hybrids with mRNAs from their respective subgroups.

The family of germ-line genes in Fig. 2*a* includes subgroups 1 and 3 sequences and their expression is therefore given by the sum of the $V_\kappa 1$ and $V_\kappa 3$ components of spleen mRNA. In spleen *a*, at least 61% and in spleen *b*, at least 53% of κ mRNA is homologous to these 25 germ-line *V* genes (Table 1). These are minimum values because it is unlikely that the two V_κ probes would form full-length exoVII-resistant hybrids with every transcript homologous to this family of germ-line genes. The exoVII protection experiments therefore substantiate the value of 75% determined by Northern blot hybridization (Fig. 2*b*). The large amount of $V_\kappa 1$ and $V_\kappa 3$ mRNA in spleen was also observed in peripheral blood lymphocytes (PBLs) from another donor. Over

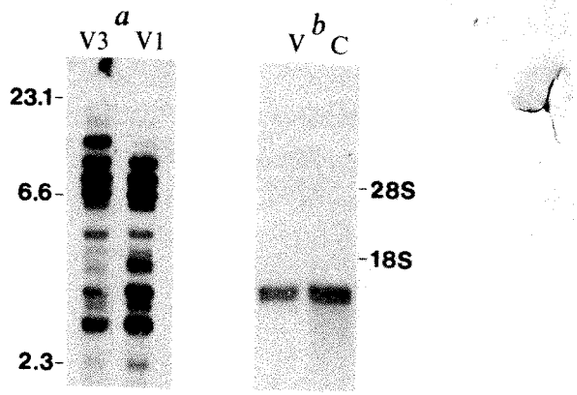

Fig. 2 *a*, Southern blot hybridization of $V_\kappa 1$ and $V_\kappa 3$ probes to human DNA. The author's peripheral blood DNA (10 μg) digested with *Bgl*II was electrophoresed in a 1% agarose gel and transferred to nitrocellulose. Adjacent tracks from the gel were hybridized to $V_\kappa 1$- and $V_\kappa 3$-specific restriction fragments labelled by nick translation or filling-in after exonuclease digestion with T4 DNA polymerase. The probes were the 558-bp *Pst*I fragment from *HK101*/80[3] which extends from 130 bases upstream of the gene to codon 79 and the 266-bp insert from *NG9*/3 excised with *Bam*HI. Hybridization was according to ref. 23 in 5×SSC, 50% formamide at 42 °C for 24 h. The blots were washed at 65 °C in 2×SSC, 0.1% SDS for 30 min and then in 50 mM Tris-HCl, *p*H 7.6, 10 mM sodium pyrophosphate, 2 mM Na_2EDTA, 1× Denhardt's solution, 0.05% SDS, 0.05% sarkosyl for 15 min. *b*, Northern blot hybridization of V_κ and C_κ probes to human spleen RNA. Poly(A)$^+$ RNA (2 μg) from spleen *b* was electrophoresed in a 1.2% formaldehyde agarose gel and blotted onto nitrocellulose[24]. Adjacent tracks were hybridized to nick-translated restriction fragments (about 1×10^8 d.p.m. per μg, 1×10^6 d.p.m. ml^{-1}) in conditions described in Fig. 2*a*. The V_κ probe was the same fragment of the *HK101* gene used in *a*. The C_κ probe was the 469-bp insert from the clone M13/C_κ6 excised with *Bam*HI[10]. The fragment extends downstream from codon 115 in the constant region. The positions of *Xenopus laevis* ribosomal RNA markers are shown.

60% of κ mRNA from PBLs hybridized to a mixture of $V_\kappa 1$ and $V_\kappa 3$ probes (Fig. 3). The diversity of the V_κ mRNA sequences detected is not known, although this important question could be answered by sequencing lymphocyte cDNA clones. What is clear from these experiments is that the majority of κ mRNA in human lymphocytes is encoded by about 25 germ-line *V* genes.

The frequencies of $V_\kappa 1$ and $V_\kappa 3$ mRNAs in spleen correspond with the frequencies of these subgroups in serum κ chains of various individuals and in the panel of sequenced myeloma proteins. The amount of subgroup 3 among serum κ-chains has been measured by serological means[12], by N-terminal sequencing of pooled light chains[13] and by isolation of a subgroup-specific peptide[14]. These studies gave average values of 21–31%. Thirty-four per cent (62/182) of sequenced myeloma chains

Table 1 Amounts of hybridization of V_κ and C_κ probes to spleen RNA

	C	*V1*	*V1/C*	*V3*	*V3/C*	*V1+V3/C*	*V1+V3/V1+3*
Spleen *a*	2.54±0.14 (3)	1.00±0.20 (6)	39%	0.55±0.03 (5)	22%	61%	100%±14% (5)
Spleen *b*	0.81±0.03 (3)	0.19±0.04 (3)	23%	0.24±0.03 (3)	30%	53%	101%±27% (3)

Values are given in pmol X 10^{-4} of probe hybridized per μg of total RNA. Means and standard deviations from at least three independent experiments are given. The number of determinations is given in parentheses. Gel slices were counted with 63% efficiency in 0.2 ml soluene (Packard) plus 2 ml Omnifluor (NEN). Actual values were between 200 and 1,200 c.p.m. Background from an equal area of gel immediately above the bands was substracted. Background values were ≤35% of total counts. The amount of probe hybridized was calculated from the number of T residues in each exoVII-resistant fragment, and the specific activity of [α-^{32}P]dTTP in the probe synthesis reaction (see Fig. 3, Methods). The number of Ts in the *V1*, *V3* and *C* fragments were 60, 52 and 37, respectively. The RNA preparation from spleen *b* was degraded relative to that from spleen *a* and this explains the lower amounts of hybridization observed. $V1+V3/V1+3$ is the ratio of the sum of the amounts of hybridization of the $V_\kappa 1$ and $V_\kappa 3$ probes alone (0.008 pmol of each per hybridization) to the amount of hybridization of a mixture of the $V_\kappa 1$ and $V_\kappa 3$ probes (0.004 pmol of each per hybridization).

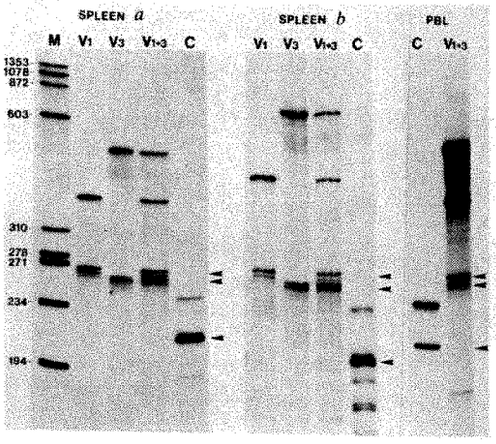

Fig. 3 Analysis of spleen and peripheral blood lymphocyte (PBL) RNA with $V_\kappa 1$, $V_\kappa 3$ and C_κ probes by exoVII protection. For each track total RNA (spleen, 3 μg; PBLs, 1 μg) prepared according to ref. 27 was hybridized to a single-stranded uniformly labelled probe, the hybrids digested with exoVII and electrophoresed on a 5% sequencing gel. Two spleens, *a* and *b*, were obtained from transplant donors. PBLs from a third individual were purified by density gradient sedimentation on Lymphoprep (Pharmacia). The tracks are labelled with the relevant probes *V*1, *V*3, *C* or *V*1 + *V*3 which was an equimolar mixture of the two *V* probes. The fragments corresponding to full-length protection of immunoglobulin sequences in the probe are arrowed. Some undigested probe is evident in each track. The larger number of less than full-length resistant fragments seen in spleen *b* is due to partial degradation of this RNA sample as judged from ethidium bromide-stained agarose gels. DNA size markers are indicated for spleen *a*. The three RNA samples shown were analysed on separate gels.

Methods: Preparation of single-stranded probes. The 'prime-cut' probes complementary to mRNA were made by primed synthesis on a single-stranded M13 template followed by cutting with a restriction enzyme. The fragment extending from the primer to the restriction site was isolated from the longer M13 template strand on a sequencing gel. In a typical reaction 1 μg of template (0.4 pmol) was annealed to 5 ng of universal 17mer sequencing primer[25] in 5 μl by heating for 30 s to 80 °C and incubating at room temperature for 20 min in 20 mM Tris-HCl *p*H 8.5, 100 mM NaCl, 20 mM $MgCl_2$, 2 mM dithiothreitol[22]. The annealing mix was diluted twofold by addition of three unlabelled nucleotide triphosphates to 100 μM and one [α-^{32}P]-labelled triphosphate at 52.5 μM with a specific activity of 37 Ci mmol^{-1}. Klenow fragment was added to 250 U ml^{-1} and the reaction incubated at room temperature for 15 min. The reaction was terminated by heating to 65 °C for 5 min and then 5–10 units of restriction enzyme was added and the mix incubated at 37 °C for 1 h. The digestion was terminated by adding Na_2EDTA to 10 mM and SDS to 0.2% and an equal volume of 98% formamide, 10 mM Na_2EDTA, 0.1% xylene cyanol and 0.1% bromophenol blue. It was boiled for 5 min and loaded on a thin denaturing sequencing gel. Single-stranded fragments were eluted from gel slices by soaking overnight at 37 °C in 0.2 ml of 0.5 M ammonium acetate, 10 mM magnesium acetate, 0.1 mM EDTA, 0.1% SDS[26]. The typical yield was 0.1 pmol or 15 ng of a 450-base fragment. Prime-cut probes synthesized in this way have an average specific activity of 6×10^7 d.p.m. per μg and are stable for several weeks. ***C*$_\kappa$ probe:** The template M13/*C*$_\kappa$6 contains a 469-base fragment starting at codon 115 and extending 170 bases into the 3′-untranslated region. This fragment was inserted into the *Hin*dII site of *mp7*. The probe was prepared by cutting with *Sac*I which cleaves between codons 201 and 202. It contained 208 bases of C_κ sequence and 35 bases of M13 sequence at the 5′ end. ***V*$_\kappa$*1* probe:** The template M13 101/320 contains a 326-base *Rsa*I–*Pst*I fragment of the *HK101* gene inserted into the *Sma*I–*Pst*I site of *mp8*. This fragment contains 77 bases of the intron and extends to codon 79. The probe was prepared by cutting with *Eco*RI which cleaves in the M13 polylinker seven bases from the end of the insert. It contained 249 bases of immunoglobulin-coding sequences and 112 bases of M13 and intron sequences at the 5′ and 3′ ends. ***V*$_\kappa$*3* probe:** The template M13 *NG9*/10 is a subclone of *NG9*/3 which contains a 243-base fragment extending from the *Hin*dII site at codon 4 to codon 84 cloned into the *Sma*I–*Bam*HI site of *mp8*. The probe was prepared by cutting with *Pvu*II which cleaves the M13 vector 183 bases from the end of the insert. It contained 243 bases of immunoglobulin-coding sequence and 232 bases of M13 sequence at the 5′ and 3′ ends. **Hybridization and exoVII digestion:** 3 μg of unfractionated spleen RNA or 1 μg of PBL RNA was hybridized to 0.008 pmol (a 10-fold molar excess over κ mRNA in spleen) of prime-cut probe (0.5–2 ng) in 5 μl of 20 mM Tris-HCl *p*H 8.0, 50 mM NaCl, 10 mM Na_2EDTA at 67 °C for 24 h in a sealed capillary. When a mixture of the two V_κ probes (*V*1 + 3) was used, 0.004 pmol of each was added. The hybrids were digested in 100 μl of the same solution containing 4 U ml^{-1} of exoVII (BRL) for 1 h at 37 °C. The reaction was terminated by ethanol precipitation and the products prepared for electrophoresis on a sequencing gel.

are subgroup 3[5]. In agreement with these values, the *NG9* $V_\kappa 3$ DNA probe hybridized to 22% and 30% of spleen RNA in two individuals. Subgroup 1 constituted 28% and 25% of serum κ chains in two studies[13,14] while 44% (81/182) of myeloma chains belong to this subgroup[5]. These values agree with frequencies of 39% and 23% obtained by hybridization of the *HK101* $V_\kappa 1$ gene to spleen RNAs. In short, the data show that spleen mRNA is a faithful representation of the κ-chain repertoire at least insofar as the contribution of the different subgroups is concerned. The agreement of the $V_\kappa 1$ and $V_\kappa 3$ frequencies determined by protein analysis and by DNA–RNA hybridization, suggests that the two cloned genes hybridize with nearly all the expressed subgroups 1 and 3 *V* region sequences. This conclusion would not be valid if each of the *V* probes by chance hybridized to transcripts from subsets of $V_\kappa 1$ and $V_\kappa 3$ genes that were expressed to a disproportionately high extent so as to coincide fortuitously with the protein data. Barring this highly unlikely possibility, the results show that close to all subgroup 1 and subgroup 3 *V*-region sequences are encoded in the germ-line by only about 25 genes.

The quantitation of V_κ sequences in lymphocyte RNA agrees with previous gene-counting experiments which showed that four quite distantly related human and mouse V_κ probes all hybridized to the same small family of *V* genes in human DNA[3]. Based on the extent of cross-hybridization observed among human V_κ sequences, it was argued that the 25 germ-line V_κ genes detected, constituted a large proportion of the total V_κ gene pool. It has now been demonstrated that this family of genes encodes over 50% of κ mRNA in human lymphocytes. Together, these data suggest that the total number of V_κ genes in the human germ line is 50 or fewer. Cory *et al.*[15] estimated that the most probable number of V_κ genes in the mouse was 90, based on statistical analysis of Southern blots hybridized to 10 different V_κ sequences. This result is consistent with the fact that the $V_\kappa 21$ group encoded by six to eight germ-line genes[16] comprises 8% of serum light chains[17]. Thus, the number of V_κ genes in the mouse germ line may also be quite small although greater than in the human germ line. Although the overall contribution of somatic mutation to the murine antibody repertoire is unknown, several examples of somatic mutation of individual *V* genes have been documented (see, for example, refs 18–20).

Comparison of the number of germ-line V_κ genes with the number of κ chains expressed by an individual allows one to assess the relative importance of the germ-line and somatic components of diversity. The number of different κ variable regions expressed in an individual is not known but it may be approximated by the repertoire of myeloma chains in the human population. Because of polymorphism, the myeloma model gives a maximum estimate for the repertoire of an individual. Quattrocchi *et al.*[21] analysed 52 myeloma proteins by peptide mapping and found that no two were identical. Also, 36 κ *V* regions of myeloma chains have been fully or almost fully sequenced[5] and no two have identical amino acid sequences up to position 95. These observations imply that in addition to the contribution of *V*–*J* joining, the number of V_κ gene-encoded sequences (amino acids 1–95) among myeloma chains is[21] at least 1,000. Direct estimates of the number of different antibodies expressed by individual mice predict a repertoire of several thousand κ-chains[1] and it is hard to see why the human repertoire should be very much smaller. It is likely, therefore, that the repertoire of V_κ gene-encoded sequences in an individual human is at least

several hundred. The small number of germ-line V_κ sequences apparently cannot account for the repertoire without extensive diversification by somatic mutation.

I thank the MRC Laboratory of Molecular Biology, T. Rabbitts, M. Bretscher and H. Weintraub for facilities, C. Milstein, M. Wickens, M. Dunaway and M. Groudine for helpful suggestions, H. Devitt for typing and particularly S. Satchwell for DNA sequencing. D.L.B. is a Beit Memorial Fellow.

A lymphocyte-specific enhancer in the mouse immunoglobulin κ gene

Didier Picard & Walter Schaffner

Institut für Molekularbiologie II der Universität Zürich, Hönggerberg, 8093 Zürich, Switzerland

During differentiation of lymphocytes into antibody-producing cells, an immunoglobulin κ variable-region gene is transcriptionally activated by rearrangement linking it to a κ constant (C_κ) region gene which is already transcribed prior to somatic rearrangement[1,2]. The presence of a transcriptional enhancer element within the large intron of the κ light-chain gene has been postulated to explain this mode of activation, supported by evidence of a chromatin region which is preferentially accessible to DNase I[3–5] and restriction enzymes[5]. This DNA region contains a segment of about 130 base pairs (bp) which is strongly conserved between mouse, rabbit and man[6]. Moreover, no transcripts are detectable from a κ gene, which is truncated within the large intron[7]. Recently, a lymphocyte-specific enhancer has been identified downstream of the joining region in immunoglobulin heavy-chain genes[8–10]. We now show direct evidence for a functionally similar enhancer within the large κ gene intron of the mouse. It is, however, less active than the heavy-chain gene enhancer. In contrast, no enhancer was found to be associated with a cloned λI light-chain gene.

Several DNA fragments from both the κ light-chain gene[11] and the λI light-chain gene[12,13] from the mouse were subcloned into a plasmid carrying the rabbit β-globin gene (Fig. 1). First we took the 2.8-kilobase (kb) *Hin*dIII–*Bam*HI fragment, which contains the 3′ half of the large intron (IVS2) and the entire constant coding region including 3′-flanking sequences of the κ gene, and inserted it downstream of the β-globin gene to yield the recombinant pβκD (Fig. 1*a*). The 7.4-kb *Eco*RI–*Eco*RI segment with the somatically rearranged λ-chain gene was subcloned as *Eco*RI–*Kpn*I fragments to give the recombinants pβλU and pβλ (Fig. 1*b*).

To study the transient expression of the β-globin gene these recombinants were transfected into mouse myeloma cells (cell line X63Ag8) by the DEAE-dextran technique. As a positive control the recombinant pTAR7 was transfected in parallel. This clone contains the immunoglobulin heavy-chain gene enhancer inserted downstream of the rabbit β-globin gene[8]. The cells were collected 40 h after transfection and the cytoplasmic RNA was analysed by a S_1 nuclease mapping experiment (Fig. 2*a*). Both pβκD, containing the κ gene fragment, and pTAR7 give rise to correctly initiated β-globin gene transcripts, although the level of transcription from pβκD is considerably lower (Fig. 2*b*). The finding of transcripts from pβκD is consistent with a recent report showing that deletion of the 2.8-kb *Hin*dIII–*Bam*HI fragment abolishes expression of the κ gene when this truncated gene is introduced into myeloma cells[7]. The recombinants with the λ gene fragments (pβλU and pβλ) gave globin gene transcripts neither in the κ chain-producing myeloma line X63Ag8 (Fig. 2*b*) nor in the myeloma line J558 (data not shown), which produces λI chains. Interestingly, even transcription of the intact λ gene transfected into myeloma cells is only detectable when the gene is linked to the simian virus 40 (SV40) or heavy-chain gene enhancer (unpublished results). This parallels the expression of the λ gene alone or linked to the SV40 enhancer on transfection into human HeLa cells[14].

To narrow down the region of the κ gene responsible for the enhancing effect, we subcloned DNA fragments from the DNase I hypersensitive region found in the large κ gene intron[3–5] (Figs 1*a*, 3*a*). These subfragments do not include the constant coding region, polyadenylation site or 3′-flanking sequences. The clone pβκD1 contains the 266-bp *Alu*I–*Hae*III fragment inserted behind the rabbit β-globin gene. In clone pβκD11 the κ gene fragment extends 209 bp further to the *Alu*I site and thus includes the entire segment of about 130 bp from the large κ gene intron (Fig. 3*b*), which is strongly conserved between mouse, rabbit and man ('κ intron conserved region')[6]. In clones pβκD2 and pβκD22 the inserts are in opposite orientation. These recombinants were also transfected into myeloma cells, and the cytoplasmic RNA was analysed by S_1 mapping. This experiment shows enhancement of β-globin gene transcription by the 475-bp κ gene fragment in either orientation (Fig. 2*c*, lanes 2, 3), whereas removal of 209 bp from the *Hae*III to the *Alu*I site abolishes the effect (Fig. 2*d*). The deletion removes about 60% of the conserved segment (Fig. 3*b*). Note that the 475-bp fragment still retains the full enhancement activity as compared with the 2.8-kb fragment in pβκD (Fig. 2*c*).

It is interesting to consider a few features of the enhancing DNA sequence (Fig. 3*b*). As DNase I hypersensitivity sites are known to be closely associated with the enhancer elements of polyoma virus[15] and SV40 [16], it is noteworthy that the inactive 266-bp κ gene intron segment retains only part of the chromatin region accessible to nucleolytic enzyme cleavage. The stretches of sequence homology[4,6] between the inactive 266-bp segment and the SV40 72-bp repeat or the polyoma enhancer segment are apparently not sufficient for enhancement. It remains to be determined whether the κ intron conserved region contains all of the enhancer activity. The κ gene enhancing element also cannot act in *trans* because co-transfection of a globin gene recombinant and the κ gene fragment subcloned in pUC8 does not yield detectable globin gene transcripts (Fig. 2*c*, lane 4). This is corroborated by the finding that the κ gene enhancer fragment does not have long open reading frames and is not detectably transcribed into an independent RNA[6]. We also conducted a transient expression assay with mouse fibroblast 3T6 cells. In contrast to a globin gene recombinant with the SV40 enhancer, pβκD22 did not give globin gene transcripts (data not shown). This indicates that the κ gene enhancer is lymphocyte specific, as was shown for the heavy-chain gene enhancer[8].

The κ gene enhancer shares common features with the previously characterized viral[17–19] and immunoglobulin heavy-

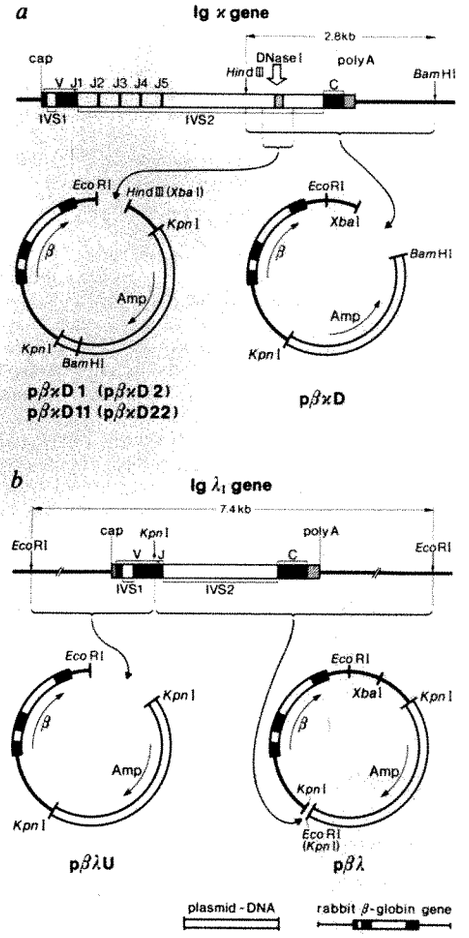

Fig. 1 Schematic representation of recombinant DNAs used. *a*, Diagram of the κ light-chain gene from the mouse myeloma MOPC-41[11,25]. The open arrow indicates the centre of the DNase I hypersensitivity site within IVS2[3–5] positioned according to ref. 4. The stippled box represents the κ intron conserved region (ref. 6, see also Fig. 3). Scheme of the strategy applied to subclone κ gene fragments into the rabbit haemoglobin β1 gene[26] recombinants pβGX and pβG- (ref. 8). pβκD: 2.8-kb *Hin*dIII–*Bam*HI κ gene fragment cloned into pβG- by fusing *Hin*dIII and *Xba*I sites. pβκD1/pβκD11: the small κ gene fragments indicated in Fig. 3 were first subcloned in either orientation into the polylinker of plasmid pUC8[27] and thereafter excised as *Eco*RI–*Hin*dIII fragments to be inserted into pβGX. Clones pβκD1 and pβκD11 thus contain the 266-bp *Alu*I–*Hae*III and the 475-bp *Alu*I–*Alu*I intron fragments (see also Fig. 3), respectively. pβκD2/pβκD22: reversed orientation of 266-bp and 475-bp intron fragments, respectively. *b*, Diagram of the mouse λI light-chain gene[12,13]. pβλU/pβλ: the two fragments generated by a partial *Kpn*I digestion of the 7.4-kb *Eco*RI fragment were inserted into the rabbit β-globin gene recombinant pβG[8]. V, J and C, variable, joining and constant regions of immunoglobulin genes. IVS1 and IVS2, intervening sequences 1 and 2.

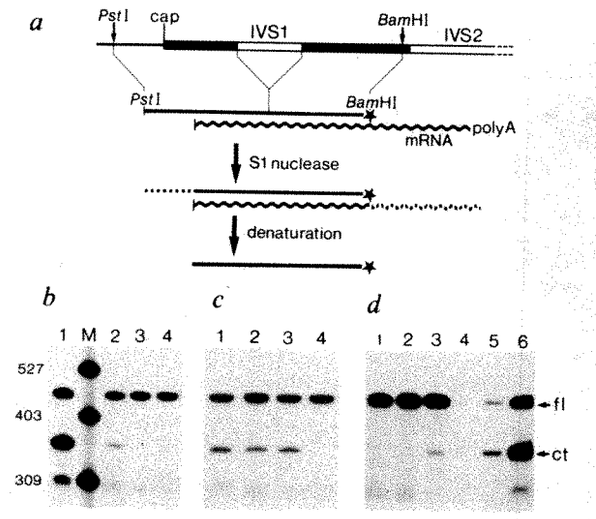

Fig. 2 Enhanced β-globin gene transcription. Tissue culture cell lines were grown and transfected as described earlier[8]. Total cytoplasmic RNA was extracted from the myeloma cells X63Ag8 40–42 h after transfection and incubated with RNase-free DNase[14] to remove residual input plasmid DNA. The recombinant pTAR7 used as a positive control contains the heavy-chain gene *Xba*I enhancer fragment cloned into the *Xba*I site of the rabbit β-globin gene recombinant pβG- (ref. 8, see also Fig. 1 legend). *a*, S_1 nuclease mapping scheme[28]. A β-globin gene clone lacking the first intervening sequence (IVS1)[29] was used to prepare the radioactive probe[30]. DNA end-labelled at the *Bam*HI site was hybridized to unlabelled RNA, treated with S_1 nuclease, denatured, fractionated by gel electrophoresis and autoradiographed (see ref. 17). *b*, Hybridization to 50 μg RNA from X63Ag8 myeloma cells transfected with recombinant pTAR7 (lane 1), pβκD (lane 2), pβλ (lane 3) and pβλU (lane 4). M, end-labelled marker DNA fragments (sizes in nucleotides) of pBR322 digested with *Hpa*II. *c*, Hybridization to 70 μg RNA from X63Ag8 myeloma cells transfected with pβκD (lane 1), pβκD11 (lane 2), pβκD22 (lane 3) and a 1:1 mixture (lane 4) of the 475-bp κ gene fragment cloned into pUC8 and the β-globin gene recombinant pβGX (see Fig. 1*a* legend). *d*, Hybridization to 90 μg RNA from X63Ag8 myeloma cells transfected with recombinant pβκD1 (lane 1), pβκD2 (lane 2) and pβκD11 (lane 3). The DNA probe protected from S_1 nuclease cleavage after hybridization to 90 μg RNA from X63Ag8 cells transfected with pTAR7 was applied to gel electrophoresis in three dilutions: lane 4, 1:50; lane 5, 1:10; lane 6, remaining 80% of protected DNA. By comparing lanes 3 and 5, the relative ratio of β-globin gene transcripts from recombinants pβκD11 (κ gene enhancer) and pTAR7 (heavy-chain gene enhancer) was estimated to be about 1:20. fl, Full-length probe (453 nucleotides); ct, fragment with correct terminus, mapping 354 nucleotides upstream from the *Bam*HI site.

chain gene enhancers[8–10]. It also acts in an orientation-independent manner over a large distance and only works in *cis*. Although there are no extended sequence homologies between the large intron of κ and heavy-chain genes[6], we consider it likely the κ gene fragment acts in the same way as the heavy-chain gene enhancer[8] and not, for example, as an uncontrolled origin of DNA replication which amplifies template copy number. Both immunoglobulin gene enhancers show a remarkable cell-type specificity. However, the κ gene enhancer is only about 5% as active as the heavy-chain gene enhancer (Fig. 2*d*) in our assays. Trivial explanations such as the quality of the DNA preparation have been excluded: the same results were obtained in several S_1 nuclease mapping experiments using independent DNA preparations; neither is it due to a deficiency of the particular myeloma line used (X63Ag8). The κ gene enhancer was also comparatively weak when pTAR7 and pβκD were transfected into the λ chain-producing myeloma J558 (not shown). The same ratio of enhancer activity was observed when the two enhancers were linked to an enhancerless SV40 T-antigen gene, and gene expression in myeloma X63Ag8 and hybridoma Sp6BU6BU was measured by immunofluorescence (not shown). Furthermore, no stimulation of κ gene enhancer activity was seen on incubation of transfected myeloma cells with bacterial lipopolysaccharide (data not shown), which in certain cells of the B-lymphocyte lineage induces the DNase I hypersensitivity region in the κ gene intron and stimulates light-chain gene transcription[3,5].

It therefore appears paradoxical that both κ and heavy-chain gene mRNAs accumulate to about the same level, have a similar turnover in myeloma cells[20], and yet the genes have enhancers of different strength. It seems possible that the low activity of the κ gene enhancer relative to the heavy-chain gene enhancer is compensated by additional transcriptional regulatory elements

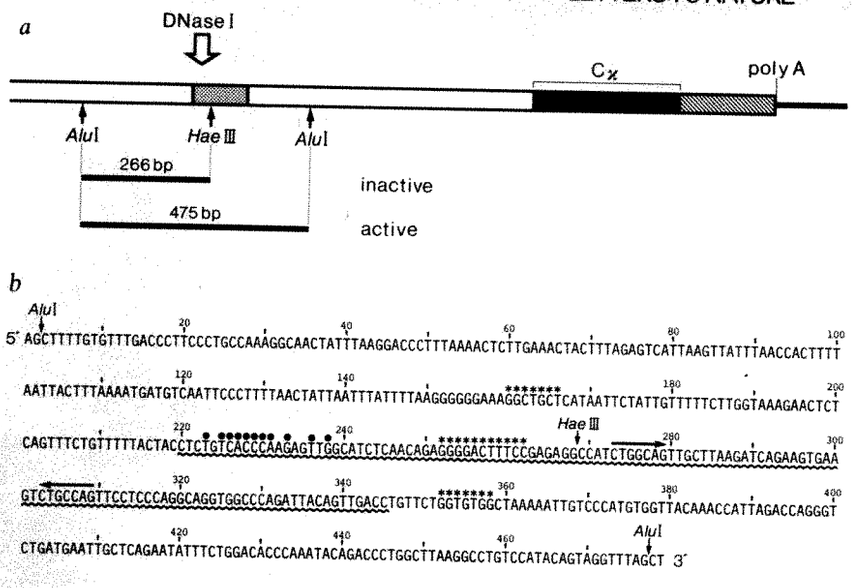

Fig. 3 κ enhancer fragments and nucleotide sequence. *a*, Enlarged schematic representation (see also Fig. 1) of κ light-chain intron (IVS2) and constant region (C_κ). Restriction sites used to generate the 266-bp and 475-bp κ enhancer fragments (black bars) are shown. Stippled box, κ intron conserved region[6]. *b*, Nucleotide sequence[5,25] of the active 475-bp κ enhancer fragment. The wavy line below the sequence represents the κ intron conserved region. Asterisks and dots above the sequence indicate sequence homologies of at least 7 bp to the SV40 (the first two blocks are mentioned in ref. 4) and polyoma virus[6] enhancer elements, respectively. Arrows indicate a 7-bp inverted repeat sequence[5]. The chromatin region, which is preferentially accessible to cleavage by DNase I[3–5] and various restriction enzymes, roughly maps to the sequence between nucleotides 180 and 420[5].

5′ to the region we have analysed. It could also mean that relative enhancer strength is only crucial in an early stage of B-cell differentiation, for example, to ensure that heavy-chain gene transcription precedes κ gene transcription. At later stages maximal transcription of both gene types could be controlled by factors acting in *trans*. In our assays, limiting factors might remain associated with the endogenous chromosomal genes. Such *trans*-acting factors have been described for 5S RNA gene transcription[21] and for 'TATA box' recognition[22], where they form 'preinitiation complexes' which are highly stable. More recently, *trans*-acting viral proteins have been described which permit efficient transcription of viral and nonviral genes even in the absence of enhancer sequences.[23]

This concept could also explain the absence of an enhancer sequence from the λ light-chain gene clone, although the latter finding may be related to the unique structure of murine λ genes[24]. As there is only one λ variable region for each of the two constant region clusters, an enhancer could also be located far upstream of the variable region.

We thank P. Leder, S. Tonegawa, S.-Y. Chung and G. Köhler for gifts of the κ light-chain gene, the λ light-chain gene, the myeloma line X63Ag8 and the myeloma line J558, respectively. We thank H. Hengartner and J. Banerji for valuable discussions, C. Southgate, G. Gilmartin, and M. L. Birnstiel for critical reading of the manuscript, and F. Ochsenbein for preparing the graphics. This work was supported by the Swiss National Research Foundation and by the Kanton of Zürich.

Conservative segregation of nucleosome core histones

I. M. Leffak

Department of Biochemistry, Wright State University, Dayton, Ohio 45435, USA

Density labelling studies have shown that nascent histones are not mixed with parental histones during the assembly of nucleosome cores[1,2]. However, experiments in other laboratories, examining histone deposition with respect to newly synthesized DNA, have been interpreted as suggesting that a substantial proportion of core histones (>15%) are randomized at each chromatin replication[3–8]. The data presented here support our previous results in showing that conservatively assembled nucleosome core histone octamers are conservatively segregated over successive cell generations. It is also shown that the nucleosome cores assembled during 1-β-D-arabinofuranosylcytosine inhibition of DNA synthesis are conservatively segregated for a minimum of five or six cell generations. These results suggest that the nonrandom assembly of nucleosome cores is not merely a coincidence of the mechanism of histone transport into the nucleus and that the conservative mode of nucleosome segregation is a fundamental feature of chromatin replication, one which is stable to modulations in chromatin packaging.

Our laboratory has previously shown that when MSB cells (a line of leukaemic chicken lymphocytes[9]) are incubated for 1 h in medium containing ^{15}N-, ^{13}C-, ^{2}H-substituted amino acids (plus tracer ^{3}H-lysine), the histone synthesized during this incubation (~5–10% of the total histones) bands with a 4–5% increase in density on denaturing isopycnic caesium formate–guanidine hydrochloride (CsFo-GuCl) gradients. By isolation of chromatin immediately after a 1-h density pulse and subsequent cross-linking of nucleosome core histone octamers, it was demonstrated that the ^{3}H-labelled octamers are conservatively assembled; that is, each octamer contains eight density-substituted histones[2].

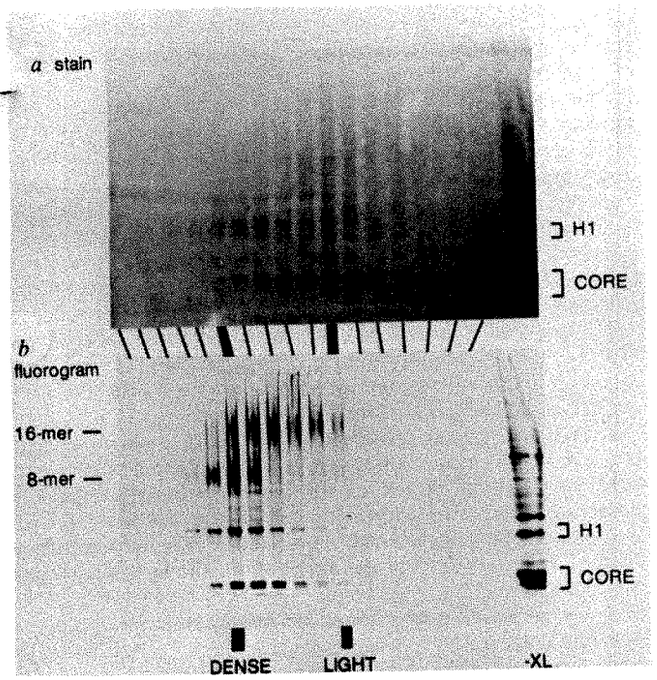

Fig. 1 Conservative segregation of nucleosome core histones. Nucleosome core octamers containing density-labelled, ^{3}H-histones were separated from unlabelled octamers on CsFo-GuCl. The gradient was analysed by SDS-PAGE. *a*, Coomassie blue stained gel. Note that bulk 8-mers and 16-mers are not readily detected due to the strongly decreased binding of Coomassie blue to chemically cross-linked histones[22]. *b*, Fluorogram. 'DENSE' ($\rho = 1.30$ g ml^{-1}) and 'LIGHT' ($\rho = 1.24$ g ml^{-1}) refer to peak positions of uncross-linked, density-substituted, ^{3}H-labelled histone and cross-linked, light, ^{14}C-labelled histone markers run in a parallel gradient. Lane marked −XL represents uncross-linked marker H1-, non-histone-depleted chromatin before centrifugation.

Methods: Exponentially growing MSB cells were washed with phosphate-buffered saline (PBS) and resuspended in 1 ml (8×10^6 cells ml^{-1}) of growth medium containing density-substituted amino acids (Merck MB1808) reconstituted to approximate RPMI-1640. After a 15-min preincubation, ^{3}H-lysine (NEN, 71 Ci mmol^{-1}, 200 μCi ml^{-1}) was added for 1 h. The cells were washed with PBS and returned to RPMI-1640 for a further 72 h of culture. Chromatin depleted in H1 and non-histone protein was isolated, an aliquot was cross-linked with dithiobissuccinimidyl propionate and the mixture of cross-linked and uncross-linked chromatin centrifuged to equilibrium on CsFo-GuCl as described previously[2]. The gradients were collected from below and fractions (65 μl) microdialysed against SDS-PAGE sample buffer[23] omitting β-mercaptoethanol at all times. Fractions were analysed by 5–22% gradient acrylamide SDS-PAGE[23]. The gel was processed for fluorography using Enhance (NEN) and exposed to preflashed[24] Kodak X-Omat AR film at −70 °C.

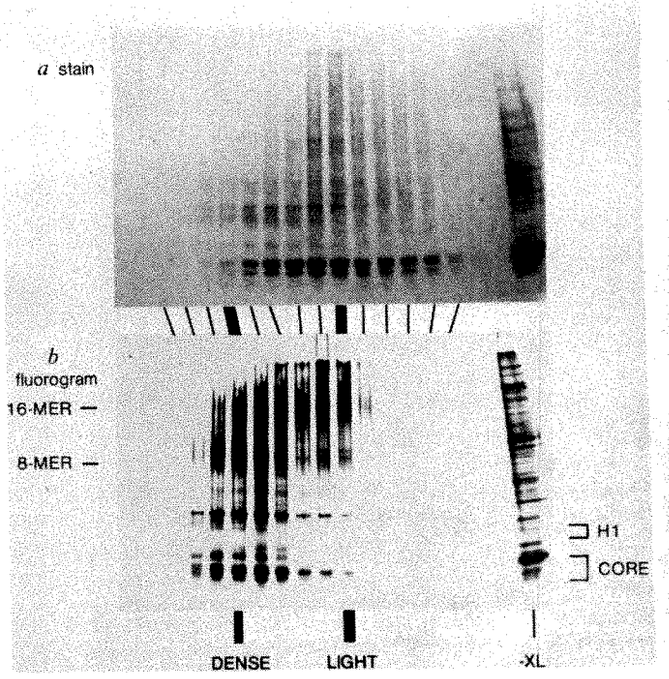

Fig. 2 Conservative segregation of nucleosome cores assembled during ara-C incubation. Octamers containing density-labelled, ^{3}H-histones synthesized during ara-C incubation were separated from unlabelled histone octamers on CsFo-GuCl. The gradient was analysed by SDS-PAGE. *a*, Stained gel; *b*, fluorogram.

Methods: An exponentially growing culture of cells was incubated for 30 min with ara-C (50 μg ml^{-1}), pelleted at low speed and resuspended in density-substituted medium containing ara-C for 30 min. ^{3}H-lysine was added to 200 μCi ml^{-1} and the incubation continued for 90 min. Cells were pelleted, washed with PBS and returned to fresh RPMI-1640 (no drug) for 72 h of culture. Depleted chromatin was isolated, cross-linked and centrifuged on a CsFo-GuCl gradient as in Fig. 1.

The conservative assembly of newly synthesized cores suggests, but does not prove, that the parental histone octamers may be inherited in a nonrandom fashion. To examine directly the stability of core histone octamers, MSB cells were pulsed for 1 h in density-substituted medium (plus tracer ^{3}H-lysine) and then washed and resuspended in their normal growth medium for an additional five or six cell generations. At this point the ^{3}H-labelled, density-substituted histone represents less than 1% of the total histone population.

Chromatin was isolated after the density labelling pulse and five to six generation chase and depleted of histone H1 and several non-histone proteins[2] so as to permit exclusive examination of the core histone octamer. The depleted chromatin was cross-linked with dithiobissuccinimidyl propionate and centrifuged to equilibrium in CsFo-GuCl. On these gradients the DNA pellets, and proteins not cross-linked to one another band independently. The gradient was fractionated and individual fractions analysed by 5–22% acrylamide gradient SDS-polyacrylamide gel electrophoresis (PAGE). The Coomassie blue stained gel of Fig. 1*a* shows the distribution of bulk (light, parental) histone in the gradient. The fluorogram of this gel (Fig. 1*b*) reveals that the histone octamers labelled with ^{3}H-lysine before the chase in unlabelled medium still appear as uniformly dense particles, as defined by the position of uncross-linked dense histones run in the same gradient. Furthermore, the density distribution of the ^{3}H-octamers assayed after the chase is the same as that before the chase[1,2]. These octamers, therefore, have been conservatively inherited.

When MSB cells are incubated in 10^{-4} M 1-β-D-arabinofuranosylcytosine (ara-C), DNA synthesis is inhibited while core histone synthesis proceeds at ~20% of control levels in 100–200-fold excess over nascent DNA[10]. In these conditions, nucleosome cores are assembled conservatively[2]; however, the structure of the chromatin synthesized during ara-C incubation is altered in that these nucleosomes adopt a shortened repeat length. On release from ara-C inhibition, the repeat length of this chromatin slowly returns to control levels[10]. This system has been used to investigate whether the nucleosome histone octamers assembled during ara-C incubation are stably maintained during drug recovery and subsequent cell growth.

MSB cells were incubated in 10^{-4} M ara-C for 2 h in the presence of density-substituted medium plus ^{3}H-lysine tracer, washed and then transferred to normal growth medium for an additional five or six cell generations. Depleted chromatin was isolated, cross-linked as described in Fig. 1 legend and centrifuged to equilibrium in CsFo-GuCl. The stained gel of Fig.

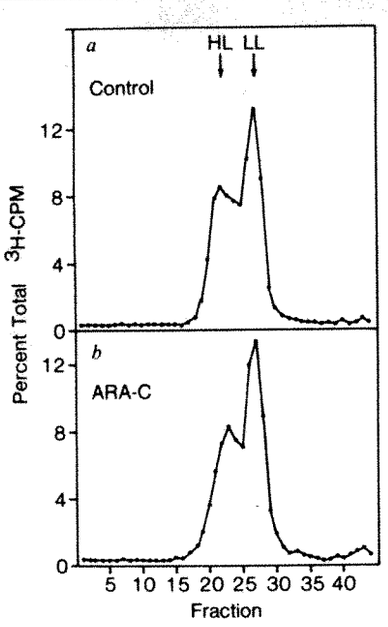

Fig. 3 Replication after ara-C incubation. The incorporation of bromodeoxyuridine by cells labelled 18 h earlier under control (*a*) or ara-C incubations (*b*) with ^{3}H-thymidine was assayed by CsCl density gradient centrifugation.

Methods: An exponentially growing cell culture was split 1 : 1 with fresh RPMI-1640 and incubated with or without ara-C (50 μg ml^{-1}) for 1 h. The cultures were concentrated to 1 ml (10^7 cells ml^{-1}) and incubated with ^{3}H-thymidine (NEN, 24 Ci mmol^{-1}) at 5 μCi ml^{-1} (control) or 200 μCi ml^{-1} (ara-C culture), for 2 h. Each culture was pelleted, washed and resuspended in warmed RPMI-1640 containing 5 μg ml^{-1} thymidine in the presence (ara-C culture) or absence (control) of ara-C for an additional hour. Cultures were pelleted and resuspended in fresh RPMI-1640 in the absence of ara-C for 18–20 h. Bromodeoxyuridine (Sigma) was added to each culture to 50 μg ml^{-1} and the cells were collected after 3 h. DNA was prepared by treatment of isolated nuclei with 10 mM Na_2EDTA, 0.2% SDS, protease K (200 μg ml^{-1}, 3 h, 37 °C), phenol extraction and ethanol precipitation. The DNA was sheared by three passages through a 26-gauge syringe needle, 50 μl mixed with 2.8 ml of 5.93 M caesium chloride and centrifuged in the Beckman SW60 Ti rotor at 30,000 r.p.m. for 48 h. Fractions were collected from below and counted in Beckman Ready-Solv MP. Arrows indicate positions of light (LL) and hybrid (HL) density markers run in parallel. (Control experiments (not shown) demonstrated that greater than 70% of the ^{3}H-thymidine in *b* was incorporated during the ara-C incubation.)

2*a* shows the banding pattern of the bulk histones while the fluorogram of Fig. 2*b* demonstrates that the ^{3}H-labelled histones synthesized during the ara-C incubation comprise uniformly dense octamers after the five to six generation chase in normal medium.

Control experiments (not shown) indicate that >85% of the ^{3}H-histone incorporation occurred during the initial ara-C incubation and that >90% of the ^{3}H-histones are retained after five or six cell doublings.

To show that MSB cells are not precluded from subsequent replications as a result of ara-C incubation, cells were incubated in the presence of ^{3}H-thymidine for 2 h with or without ara-C. After washing and resuspension in drug-free medium overnight, the cells were transferred to medium containing bromodeoxyuridine for 3 h. Figure 3 demonstrates that after the bromodeoxyuridine pulse ~30% of the total cellular DNA is found to exhibit a heavy–light density. (Similar results are obtained when the initial incubation is performed in dense amino acid medium with or without ara-C (not shown).) This is the amount of hybrid density DNA expected based on the fraction of cells in S phase during the bromodeoxyuridine pulse. Therefore, the nucleosome cores assembled during ara-C incubation are able to replicate thereafter, and the histone octamer is stably inherited.

The conservative segregation of histones is a stringent biological test of nonrandom nucleosome assembly. The present results are therefore inconsistent with recent reports that 15% or more of nascent core histones are assembled at random into chromatin[3–8]. In this type of experiment, a result suggesting random deposition or segregation of histones must be considered in the light of undiscerned artefactual randomization. A nonrandom result, however, cannot have arisen artefactually. Randomization of 15% of the core histones at each replication would result in >75% of the ^{3}H-labelled histones banding in hybrid density particles close to the light marker after the five to six generation chase in our experiments. This is clearly not the case.

The present observations agree with the novel experiments of Prior *et al.*[11] showing that exogenous histone H3 molecules taken up by *Physarum* microplasmodia are both conservatively assembled and segregated in nucleosomes.

Although the data presented in this work indicate that, in general, the associations between histones within a nucleosome core are stable during replication, these experiments might not detect an alternative segregation mechanism for a small subpopulation of histones. In this regard, it is of interest that in each of several repeats of the experiments shown in Figs 1 and 2, a small amount of hybrid density ^{3}H-octamers (≤10% of the octamer population, as assayed by densitometry) is observed near the light region of the gradient. While it is possible that a variable 1–2% of the total ^{3}H-histones segregates randomly at each replication, the conservative assembly[1,2] and segregation of the vast majority of histone suggest that it may be more likely that a larger, invariant subpopulation of the ^{3}H-histones (≈10%) segregates following a nonrandom pattern which is distinct from that of bulk histone.

These experiments do not directly address the question of the stability of the interaction between a core histone octamer and a particular DNA strand. Several reports have suggested that during replication parental histones may be nonrandomly segregated with respect to one or the other DNA strand[12–19] (but see ref. 20). The present data are not inconsistent with these observations.

The fluorogram of Fig. 1*b* indicates that after five or six cell generations there has been no mixing of new and old histones within individual octamers; however, most of the 16-mer particles band with hybrid density. In contrast, when 16-mers are examined immediately after deposition, no more than 10–20% show a hybrid density (compare Fig. 2, ref. 2). If the 16-mer particles result from the cross-linking of linearly contiguous octamer cores, the present data suggest that, as a result of repeated replication in normal medium, most dense octamers have come to be alongside light octamers. This situation could arise if individual nucleosomes segregated randomly (with respect to DNA strand) or if a domain of oligonucleosomes segregated conservatively[21] but the boundaries of such a domain were variable.

When DNA synthesis is inhibited by ara-C the deposition of newly synthesized histone octamers is accompanied by a decrease in the nucleosome repeat length[10]. The chromatin is subsequently remodelled such that the repeat length returns to normal. The results presented here show that the integrity of the octamer core is stable despite repositioning with respect to DNA sequence and modulation of chromatin packaging.

My thanks to Ms Charlene Steel for her technical assistance. This work was supported in part by grants from the NIH and NSF.

Timing of the steps in transformation of C3H 10T½ cells by X-irradiation

Ann R. Kennedy, John Cairns & John B. Little

Department of Cancer Biology, Harvard University School of Public Health, Boston, Massachusetts 02115, USA

Transformation of cells in culture by chemical carcinogens or X rays seems to require at least two steps. The initial step is a frequent event; for example, after transient exposure to either methylcholanthrene or X rays, almost every cell of established lines of mouse embryo fibroblasts proved capable of yielding transformed, tumorigenic descendants[1–3]. Although results were interpreted as indicating that 100% of the progeny of methylcholanthrene-treated cells were potentially transformed[1], later experiments showed that only a very small minority of the progeny of cells initiated by X rays[2] or methylcholanthrene[3] actually produced transformed colonies. We thus concluded[2] that there must be a second step in transformation that is a very rare event. We assumed that this event occurred after the cultures became confluent, a time when transformed cells have a selective growth advantage. Since then, however, others have shown that transformation can occur soon after initiation[4] and that clones of transformed cells may already be present by the time initiated cultures become confluent[5]. It has been hypothesized that the second step behaves like a spontaneous mutation in having a constant but small probability of occurring each time an initiated cell divides[3,6]. We show here that the clone size distribution of transformed cells in growing cultures initiated by X rays is, indeed, exactly what would be expected on that hypothesis.

If events such as mutations are scattered at random throughout the lineage of a growing population of cells, the number of mutants finally present will vary greatly from one culture to another; this is the basis for the Luria–Delbrück fluctuation test[7]. With a mutation rate of μ per cell generation, populations undergoing binary fission will on the average have experienced $2\mu N$ mutations by the time they contain N cells, namely, μN events in the last generation, $\mu N/2$ in the previous generation, and so on to give a total of $2\mu N$. The proportion of such populations that have not had an event and therefore contain no mutants will simply be $P_0 = e^{-2\mu N}$. Because clones that contain a single mutant cell can have arisen only among the final generation of cells, the proportion of cultures that contain exactly one mutant will be the proportion that had no mutations before the last generation and exactly one mutation in the last generation, that is, $P_1 = e^{-\mu N}(\mu N\, e^{-\mu N}) = \mu N\, e^{-2\mu N}$. Unfortunately, the expression for the higher terms of the distribution is more complex because any particular number of mutants could have been achieved in several ways; for example, there could be two mutants as the result of two events in the final generation or one event in the previous generation; and as the number of mutants becomes larger, so the ways of achieving that number become more numerous. But the higher terms can be obtained from Lea and Coulson[8] who have tabulated the value of P_r for different values of r and $2\mu N$ (which they call m).

Table 1 Number of transformed cells in cultures exposed to 600 rad, grown to confluence and then reseeded

Treatment group		No. of transformed foci in each dish
Group I		0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
28 cultures, not reseeded		1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
		2, 2, 2, 3, 3, 4, 4, 4
Group II		
27 cultures, each totally		0, 0, 0, 0, 0, 0, 0, 0, 0,
reseeded on to a single dish		1, 1, 1, 1, 1, 1, 1, 1, 2
		2, 3, 4, 4, 5, 5, 7, 12, 19
Group III		
14 cultures, each totally	(*a*)	0, 0, 0, 0, 1, 1, 1, 1, 2, 0, 0, 1, 6, 40
reseeded on to two dishes	(*b*)	0, 0, 0, 0, 0, 1, 2, 4, 5, c, c, c, c, c,
Group IV		0, 0, 0, 0, 0, 0, 0, 0, 1, 1,
28 cultures, each 80%		1, 1, 1, 2, 2, 2, 2, 3, 3,
reseeded on to one dish		4, 4, 5, 5, 5, 13, 15, 22

Stock cultures of C3H 10T½ cells were maintained in 60-mm Petri dishes and were passed by subculturing at a 1:20 dilution every 7 days. The cells used in this experiment were in passage 9. Cells were grown in a humidified 5% CO_2 atmosphere at 37 °C in Eagle's basal medium supplemented with fetal calf serum (10% for the first 2 weeks of the transformation assay period, and 5% for the last 4 weeks) and gentamycin (5 μg ml^{-1}). Dishes were seeded with 12,000 cells and 24 h later were irradiated with 600 rad. As the plating efficiency at this stage in the experiment was 20% and the survival after 600 rad is ~10%, each dish started with an average of 240 surviving irradiated cells. In group I the dishes were not trypsinized. In group II, the cultures were trypsinized as they approached confluence and the cells were then reseeded into their original dishes. In group III, the cultures were trypsinized and reseeded into two separate dishes (*a* and *b*). In group IV, the cells were treated as in group II, except that 20% of the trypsinized suspension was removed to form part of a separate experiment. In the paired sample of group III, c indicates that the culture was lost due to contamination; in groups I, II and IV, dishes lost due to contamination are not included. Types 2 and 3 transformed foci were scored as previously described[2]. When cells are re-plated at the high cell densities used here, the plating efficiency is assumed to be at least 50%. We have previously observed that about 50% of cells transformed by X-irradiation will grow, and form transformed foci when reseeded onto confluent monolayers of untreated C3H10T½ cells[15].

To determine the actual distribution of transformed clone sizes, cultures of C3H 10T½ cells were irradiated with 600 rad of X rays, a dose that kills 90% of the cells, and initiates virtually all those that survive[2]. After growth of the surviving cells to near confluence (about 13 generations), each culture was trypsinized, suspended and totally reseeded on to one or more plates that were maintained for 4 additional weeks, at which time the foci of transformed cells were counted; at the same time, some plates were not reseeded, but were left untouched.

As Table 1 shows, the process of trypsinization and reseeding did not produce any change in the proportion of cultures having one or more transformed foci. Roughly one-third of the cultures yielded no transformed foci. Therefore, $2\mu N$ should be approximately equal to one. Table 2 compares the observed distribution of transformed clone sizes with the values expected on the assumption that the rare step in transformation occurs at random during exponential growth of the progeny of initiated cells and that there is, on the average, one such event per culture. As the differences between observed and expected are not significant, it seems that the second step is indeed occurring at random. The stages in such *in vitro* transformation can therefore be summarized as follows.

Although the initial step is driven by mutagenic carcinogens and creates a fairly stable heritable state, it is unlikely to be a mutation because a single treatment with X rays or methylcholanthrene can initiate almost every cell[1–3,9]. Furthermore, lower doses of initiator seem to place cells in an intermediate

Table 2 Comparison of expected and observed distributions of clone sizes for the data presented in Table 1

	No. of transformed colonies in reseeded groups (r)								
	0	1	2	3–4	5–8	9–16	17–32	33–64	>64
Probability that a culture has r transformants (mutants) when the average number (m) of events (mutations) per culture is 1 (ref. 8, Table 2)	0.3679	0.1839	0.1073	0.1164	0.0961	0.0617	0.0335	0.0168	0.0163
Data for 36 reseeded cultures of groups II and III (i)									
Observed no. of dishes containing r transformed foci	13	9	3	4	5	1	1	0	0
Expected no., from the above probabilities	13.2	6.6	3.9	4.2	3.5	2.2	1.2	0.6	0.6
Data for 69 reseeded dishes of groups II–IV (ii)									
Observed no. of dishes containing r transformed foci	23	14	9	8	8	4	2	0	1
Expected no., from the above probabilities	25.4	12.7	7.4	8.0	6.6	4.3	2.3	1.2	1.1

Comparison (i) excludes those pairs of dishes in group III where one dish was contaminated. The clone size for the uncontaminated pairs was taken to be the sum of the transformed colonies in the two dishes. Comparison (ii) is for all the reseeded groups. The count for any contaminated dish in group III was assumed to be the same as its uncontaminated companion dish. No correction was made in group IV for the fact that only 80% of each culture was reseeded.

condition. In the present experiments, 600 rad produced an initiated state that survived unchanged for at least 13 cell generations, but others have shown that the initiated state produced by exposure to 1.0 μg ml^{-1} methylcholanthrene is unstable, with about a quarter of the cells reverting to normality in each generation[3]. Similarly, in experiments reported elsewhere[9–11], we have found that treating initiated cultures with phorbol esters will greatly increase the number of transformants if the initiation was with 100–400 rad, but has hardly any effect after 600 rad; this too suggests that there are degrees of initiation. At present, the most likely hypothesis is that the initial step consists of some change in the pattern of gene expression that, like the SOS response of bacteria treated with mutagens, determines the frequency of subsequent rare genetic events. Even though initiation is much more stable than the SOS response, this hypothesis is supported by our finding that certain protease inhibitors, which are known to block the SOS response[12], will reverse the initial step in transformation[13].

In contrast, the second step is a rare, random event, occurring in slightly less than one in a million descendants of cells that have taken the first step. In the experiment reported here, the largest clone of transformed cells did not arise until 6 cell divisions after X-irradiation (that is, about 7 generations before the culture was reseeded) and most of the clones arose after 12–13 divisions. Thus, the second step cannot be the direct result of the lesions produced in DNA by the initial dose of radiation. We have observed (unpublished experiments) that the number of transformed foci arising in cultures derived from cells fully initiated with 600 rad of X rays cannot be significantly raised by treating the cultures as they approach confluence with mutagens such as X rays or UV light. If the second step is a mutation (as its frequency and random distribution might suggest), it must represent an unusual class of genetic event that is not readily driven by mutagens.

Although the nature of the steps in the neoplastic transformation of established, immortal cell lines by carcinogens is not understood, what appears to be kinetically a rather similar sequence of events has been observed for radiation-induced recombination in yeast[14]. Additional steps would probably be needed to transform normal cells *in vivo* and the kinetics of these steps have not yet been studied in similar detail.

We thank Mrs Babette Radner for technical assistance in these studies. This research was supported by contract 77EVO4322.A002 from the US Department of Energy and Center Grant ES-00002 from the US National Institute of Environmental Health Sciences.

ANNOUNCING

NEW FOR 1984

Pharmaceutical Medicine

The contents will include:

★ **Original papers**
- on methods used to evaluate the efficacy and safety of drugs in man
- with emphasis on the validation of these methods
- covering human pharmacology, clinical research, drug epidemiology, and safety surveillance
- and especially the application of new methods to drug testing

★ **Abstracts of methodological studies published elsewhere**
- either used already in the context of drug investigation
- or methods suitable for drug evaluation

★ **Invited reviews on topics related to pharmaceutical medicine**

★ **Editorials and Commentaries**
- offering opinions
- high-lighting problems

★ **Correspondence, Book Reviews, and Calendar**

SCIENTIFIC & MEDICAL | M | MACMILLAN PRESS LTD

Circle No.67 on Reader Service Card.

New Books Spring 1984: Oxford University Press

Oxford Science Publications
Oxford Medical Publications

Astronomy

Gamma Ray Astronomy

Rodney Hillier

An important new text providing a concise and critical account of the observations in gamma ray astronomy, and their interpretation.

0 19 851451 4 £15 460 pp.
Clarendon Press

Civil Engineering

Introduction to the Theory of Thin-walled Structures

N. W. Murray

A monograph for both students and professional civil engineers, introducing the theoretical aspects of the behaviour of thin-walled structures, particularly in relation to their collapse mode.

0 19 856151 2 £55 400 pp.
Clarendon Press

Electrical Engineering

Lectures on the Electrical Properties of Materials, third edition

L. Solymar and D. Walsh

The third edition of this extensively used text book for engineering and materials science students incorporates much updated work in the areas of semiconductors and lasers.

0 19 851163 9 £20
0 19 851162 0 £8.95 Paperback
420 pp. Clarendon Press

Semiconductor Contacts: an approach to ideas and models

Heinz K. Henisch

The only specialized study of semiconductor contacts, this book will bridge the gap between the available high-level abstractions of the modern theory of solids, and the phenomenological treatments employed in device physics.

0 19 852016 6 £50 400 pp.
Clarendon Press

Oxford Studies in Advanced Manufacturing

Metal Cutting Principles

Milton C. Shaw

For students of materials and mechanical sciences, and research and design engineers in industry this book provides a comprehensive account of the important topic of metal cutting as a means of removing unwanted material in the production of mechanical components.

0 19 859002 4 £60 600 pp.
Clarendon Press

Mathematics for Scientists

Free and Moving Boundary Problems

John Crank

The first work to be devoted to a comprehensive coverage of free and moving boundary problems. It includes a full account of the mathematical formulation of these problems, and offers many new methods for their solution.

0 19 853357 8 £40 424 pp.
Clarendon Press

Oxford Logic Guides

Two new titles:

Subrecursion: Functions and Hierarchies

H. E. Rose

An invaluable text for graduate courses, and a reference work for research workers, this book collects together a number of important results in recursion theory developed over the last thirty years.

0 19 853189 3 £20 200 pp.
Clarendon Press

Cantorian Set Theory and Limitation of Size

Michael Hallett

Fulfils the need for a clear understanding of classical set theory which has been necessitated by the philosophical challenges to Cantorian notions of set and of completed infinity.

0 19 853179 6 £25 280 pp.
Clarendon Press

Royal Microscopical Society Microscopy Handbooks

Oxford University Press and the Royal Microscopical Society announce the publication of the Royal Microscopy Handbooks: a major new series for all users of light and electron microscopes which will provide a balanced range of short and inexpensive books that cover both introductory and advanced topics.

Titles to be published Spring 1984

Introduction to the Optical Microscope,
Savile Bradbury
0 19 854401 £2.95 88 pp.

The Operation of the Transmission Electron Microscope,
Dawn Chescoe and Peter Goodhew
0 19 856402 3 £2.95 64 pp.

Specimen Preparation for Transmission Electron Microscopy of Materials,
Peter Goodhew
0 19 856403 1 £4.95 64 pp.

Histochemical Protein Staining Methods,
J. James and J. Tas
0 19 856406 6 £4.95 64 pp.

Lipid Histochemistry,
Olga Bayliss High
0 19 856405 8 £4.95 64 pp.

Animal Behaviour

Insects in Camera

A Photographic Essay on Behaviour
Christopher O'Toole.
Photographs by Ken Preston-Mafam

In the seven sections, each built round a major theme in the lives of insects, this book illustrates the many and sometimes bizarre ways in which they have responded to the great imperative of evolutionary success: 'adapt or perish'.

0 19 217694 3 287 colour plates
£12.95

Social Odours in Mammals
Edited by Richard E. Brown
and David W. Macdonald

The editors here review current knowledge of mammalian olfactory communication, present new information, and provide a synthesis that emphasizes a wider socio-biological framework.

0 19 857546 7 Illustrated £45
Clarendon Press

Forestry

Plantation Forestry in the Tropics

Julian Evans

'Will be particularly welcomed by all those concerned with forestry and land use in the tropics.'
Quarterly Journal of Forestry
0 19 859489 5 Illustrated
New as Paperback £12.00

Soil Survey

Soil Survey for Engineering

A. B. A. Brink, T. C. Partridge,
and A. A. B. Williams

Provides practical information on basic soil survey procedures for engineering projects. 0 19 854583 5 Illustrated New as Paperback £12.50 *Monographs on Soil Survey* Clarendon Press

Psychology

Visual Masking
An Integrative Approach

Bruno G. Breitmeyer

Here for the first time is a comprehensive and integrated account of visual masking and its related phenomena: visual persistence and integration.
0 19 852105 7 Illustrated £22.50
Oxford Psychology Series 4
Clarendon Press

Child's Talk

Learning to Use Language

Jerome Bruner

Explores how the young child acquires the *uses* of his native language, and how by using language first for limited ends, the child comes finally to recognize its more powerful, productive uses.
0 19 857613 7 £11
0 19 857511 4 Paperback £5.95

Medicine

Transplantation Immunology

Clinical and Experimental
Edited by R. Y. Calne

This major book, written by a team of clinicians and immunologists who have pioneered and developed many new transplantation procedures, considers both clinical work and *in vitro* experimental results in each of the five sections.
0 19 261414 2 Illustrated £40

Exotica

A Further Miscellany of Clinical
and Pathological Experiences
William St. Clair Symmers

A collection of unusual clinical and laboratory experiences ranging from the commonplace to the exotic and bizarre.
0 19 261225 5 Illustrated £8.95

Immunology of Reproduction

Edited by Thomas G. Wegmann
and Thomas J. Gill III

Based on the May 1981 International Conference on Reproductive Immunology, this book offers a comprehensive, up-to-date survey of this rapidly expanding field.
0 19 503096 6 Illustrated £30

Aneuploidy

D. J. Bond and A. C. Chandley

Assembles the currently available information about aneuploidy and presents data from a range of species from fungi to man. 0 19 261376 6
Illustrated £25 *Oxford Monographs on Medical Genetics*

Circle No. 10 on Reader Service Card.

What we know about acid rain

Kenneth Mellanby

Acid Rain: A Review of the Phenomenon in the EEC & Europe.
Compiled by Environmental Resources Limited.
Graham & Trotman, Sterling House, 66 Wilton Rd, London SW1/Unipub, POB 433, Murray Hill Station, NY 10157: 1983. Pp.159. £12.50, $23.

In 1982 Environmental Resources Limited (ERL), a private consultancy in London, received a contract from the Commission of the European Communities (EEC) to survey the problem of "acid rain". ERL rightly interpreted their brief to include all acid pollution produced by industry and the burning of fossil fuels. They also considered ozone, another pollutant of industrial origin, which may have its own harmful effects but which may also play a part in the generation of strong acids from other chemicals in the atmosphere.

The result, now published in book format, is a succinct and practical account, summarizing a vast amount of information in 160 pages, which include 15 of references. This bibliography is selective, but contains most useful publications up to 1982. With this volume available, there is no longer any excuse for journalists to continue to produce the uninformed nonsense they have inflicted on the public in recent months.

It is clear that when we are considering the direct phytotoxic effects of acid emissions, it is when they are in the form of gases, and to a lesser extent, of particles, that they are important. It is dry deposition that does the damage. This is something with which we have been familiar for more than a hundred years, but recently opinions may have become confused by allegations that polluted rainwater — "acid rain" — may be even more important. ERL give all the facts to allow the reader to disentangle the effects of dry and wet deposition. They make clear that, as far as direct damage to foliage and buildings is concerned, the acid rain commonly falling in the south of England has little harmful effect. Its acidity is thus something of a red herring, even though it is the property which has caused the greatest public disquiet.

Acute phytotoxicity in Britain has in fact greatly decreased in recent years, though this point is hardly made in the report. The improvement is generally attributed to the Clean Air Act of 1956, but was mainly caused by the substitution of clean, convenient natural gas for dirty coal in homes and industry. It has also been achieved by blowing the flue gases from coal-fired generating stations (still the biggest sources of sulphur dioxide) up tall chimneys so that they are mixed with air and thus diluted below the levels where plants are severely harmed.

This policy, obviously beneficial to Britain, has been severely criticized elsewhere. For instance a recent Swedish leaflet, handed out to tourists visiting that country, alleged that Britain is being selfish, reducing pollution at home by increasing it abroad. Fortunately this is not strictly true. Even with low chimneys only a small (though very damaging) amount of sulphur dioxide is deposited locally; most of it mixes into the atmosphere. So though higher chimneys produce important local reductions of pollution, they do not put much more sulphuric acid into the atmosphere; thus the gaseous concentrations a hundred or more miles from source are much the same whatever the height at which the emission originally took place.

The Swedish countryside's secret: The acid rain is slowly killing it.

Sulphur and nitrogen from the combustion of oil and coal fall with the rain, in the form of acid. This acid damages both the land, and the water. 18,000 lakes in Sweden have already been damaged by acid rain. Thousands of them are practically dead. If nothing is done, many more will soon be badly affected. The soil, the forests, and the subsoil water are also being damaged.

Acidification is our worst single environment problem. And yet many people are still unaware of this. It cannot be seen in the countryside. An acidified lake looks clean and clear, even if it has been poisoned to death.

Acidification is an international environment problem. That is why we say that what is happening in the Swedish countryside matters to you. Air pollutants are carried across countries, and across national frontiers, by the winds. Three quarters of the sulphur falling over Sweden originates from other countries.

The only way of saving our countryside from acidification is to reduce radically discharges in Europe, primarily of sulphur. This can only be achieved by international collaboration. And that is why we are concerned to tell you about acidification — by making the problem known in your own country, you will be helping us to solve it!

Acid rain and international relations — detail from a leaflet, intended for tourists, issued by Swedish conservation and angling bodies.

Until recently, it was thought that the policy of "dilute and disperse" had been completely successful, both locally and on a global scale. However, we now find that some damage may occur to crops and trees from levels of gases below those where acute damage is evident. This seems particularly true when the oxides of sulphur and nitrogen mix with ozone. Nevertheless this is still a local problem, occurring within a radius of perhaps up to two hundred miles from the pollution source. Further off, with greater dilution, no further direct damage to plants or to buildings occurs. Until recently we thought that these very dilute gases were completely harmless, and that the pollution problem had largely been solved.

Unfortunately, it has not proved to be so simple. In Scandinavia, for instance, the levels of sulphur dioxide, a substantial part of which comes from Britain, are indeed low, and cause no direct damage to plant life. In fact very delicate foliose lichens, well known biological indicators of air pollution, flourish. But lakes and rivers are becoming acidic, fish are disappearing, and in some parts of Europe (though not in Scandinavia) trees appear to be damaged. This is all blamed on acid rain, and as the chemicals producing the acidity blow from one country to another, the problem is an international one.

A major cause of damage is believed to be that as the air passes from one area to another, perhaps taking several days to do so, the sulphur dioxide is transformed slowly to sulphate and sulphuric acid. This is washed out of the air, and may then acidify lakes, streams and soils where calcium levels are low and there is poor buffering. The rain itself, even when it contains sulphuric acid, is so dilute that it has no direct phytotoxicity; it is the indirect effect on the soil which is thought to be important.

But there are still many uncertainties. We simply do not understand the quantitative relationships between emissions and their environmental effects. One American report showed a linear relationship, with damage closely correlated with the amounts of pollution emitted. European studies have shown no such correlation. This disparity may be because different phenomena are being investigated. The local effects within the UK of air pollution generated in Britain are roughly proportional to emissions, certainly within a radius of a couple of hundred miles from source. But more distant effects, involving chemical transformations whose rate depends on several factors, cannot be determined so easily.

The value of this publication is that it summarizes the existing information, and shows how little we know and where research is needed. I cannot describe the situation better than by quoting from the summary:

> However, it has not been unequivocably established that these environmental impacts are caused by acid pollutant emissions, nor is the relative importance of other factors properly identified. Also considerable further investigations are required to understand the mechanism involved. Nevertheless circumstantial evidence would suggest that acid emissions and their subsequent chemical transformation and precipitation are at least a partial contributory cause to the observed effects and may be giving rise to as yet unidentified impacts, some of which could be irreversible. □

Kenneth Mellanby is Chairman of the Working Group on Acid Rain of the Watt Committee on Energy. This committee represents 60 British professional engineering and scientific organizations.

Ageing friends at a congenial meeting

Alex Comfort

Aging: An Exploration. By David Barash. *University of Washington Press: 1983. Pp.240. $14.95, £12.75.*

POPULAR books on ageing are rather like conferences on a recondite area of research — they tend to be parades of familiar faces. One greets the quotations and examples like old friends and looks out for those who should be there. Professor Barash's book is an entertaining reworking of Visscher, Ernest and other — largely prescientific — writers on age. Unfortunately, while the literary background is colourful and some of the social comment is acute, the corpus of modern gerontological research has largely passed Barash by: he is still going on about Orgel's error hypothesis and Bidder on growth, and about the Vilcabambans and Abkhasians, when the focus of potential application has shifted to the hypothalamus, to immunology and to other areas largely ignored here.

The book is well-written, amusing and accurate in terms of the gerontology of, say, 1960 (though Barash regrettably attributes Frederick the Great's classic exhortation in battle — "Sons of bitches! D'you want to live forever?" to an American sergeant). But it fails altogether to project ageing research as the going concern which it is: there is little or nothing about research prospects, and a good deal too much about the history of quackery. This is partly because the earlier gerontologists made their point and entered the nature of ageing in the agenda of their colleagues — in neurotransmitter studies, for example — but it makes the book a little dated, and unlikely to inspire younger researchers to take up the subject and secure clinically applicable results. □

Alex Comfort is Consultant in Geriatric Psychiatry to the Veterans' Administration, Los Angeles, and an Adjunct Professor at the University of California, Los Angeles.

Dynamics of dizzy nuclei

Neil Rowley

Fast Nuclear Rotation.
By Zdzisław Szymański.
Oxford University Press: 1983. Pp.250. £35, $39.

IN ATOMIC and solid-state physics much can be learned about the internal dynamics of a system by the application of external electric and magnetic fields. The nucleus, however, is a strongly bound object and, in the laboratory, it is not possible to create fields that are sufficiently strong to perturb its internal structure. One extremely fruitful alternative is to set the nucleus spinning and see how its structure responds to the resulting inertial forces. Our knowledge of nuclear structure has greatly increased over the past ten years or more through the application of this idea, and in *Fast Nuclear Rotation* Szymański has set out to document the relevant theoretical and experimental advances.

For a rotating system one can generalize the concept of a quantum mechanical ground state by talking of the configuration which has the lowest energy for a given value of the angular momentum. Equivalently the set of states defined in this way may be thought of as having the largest possible spins for given excitation energies, and are referred to as the "yrast" states of the system. ("Yrast", as Szymański explains, is the superlative of the Swedish "yr", meaning dizzy.)

For sufficiently rapid rotations the entire nuclear shape will be modified and may undergo violent convulsions in an attempt to minimize its energy while accommodating large amounts of angular momentum. It is finally unable to find any equilibrium configuration and will be torn apart by the enormous centrifugal forces present. The book takes us up the entire yrast line from the low-spin region to this ultimate demise into fission fragments. Along this path many fascinating changes in internal structure take place, and it is the observation of these nuclear "glitches" (e.g. sudden changes in the moment of inertia) and their interpretation in terms of the underlying nucleon motions which is the aim of the field of nuclear high-spin states.

As is described in the book, the most usual way of producing a rapidly rotating nucleus is by the so-called fusion–evaporation mechanism in which two nuclei are caused to collide at energies high enough to overcome their mutual Coulomb repulsion. The fused system produced in this way has a high angular momentum and a large excitation energy. Indeed for any given spin, the energy of the compound nucleus will be significantly higher than the corresponding yrast energy and the system may be thought of as being hot. Just like a hot classical liquid, the droplet of hot nuclear matter cools by "evaporation", i.e. by rapid emission of neutrons, protons and alpha particles which carry away large amounts of energy but little angular momentum. (In addition to producing high-spin states the evaporation process may also be used to produce exotic β-unstable isotopes.) On reaching a lower temperature the nucleus can no longer emit particles and the subsequent energy and spin losses must take place via series of γ-decays into and through the yrast states or down the many other "side-bands", i.e. sequences of higher energy rotational states. It is the experimental observation of the ensuing γ-cascades which is the key to the elucidation of nuclear structure at high spins. The sophistication of experimental devices and techniques has grown enormously in recent years, allowing one to resolve individual γ-decays from states with spins in excess of forty units of angular momentum. Indeed many significant advances have been made since the manuscript of *Fast Nuclear Rotation* was completed, though this is a reflection of the vitality of the subject rather than too serious a criticism of Szymański's treatment in the book.

Many of the phenomena associated with nuclear rotations can be thought of in a semiclassical way. Indeed the very phrase "nuclear rotations" implies that it is possible to think of the nuclei in question as deformed objects rotating with some classical angular velocity, which is in turn related to the frequency of the emitted γ-rays. Although typical rotations may seem rather fast ($\sim 10^{20}$ revolutions per second) they correspond to velocities of the nuclear surface significantly less than those of the individual nucleons through the nuclear interior. It is, therefore, meaningful to think of a particle moving in an average field generated by all the others, and of this field rotating in space. This notion leads to the cranked shell model for high-spin states and Szymański discusses many successes of this model in detail. For example the phenomenon of backbending (a decrease in rotational velocity accompanying an increase in angular momentum) is explained in terms of the effect of the Coriolis force on the individual nucleons. In the nuclear ground state nucleons tend to be coupled in pairs, with zero total angular momentum, while the Coriolis force tends to align their individual angular momenta with the axis of rotation. This increases the total spin of the system even though its collective rotational velocity may drop as a given pair is broken up. The interplay between such collective and single-particle effects is central to this area of study and is well brought out in the book.

In order to understand the relevance of high-spin phenomena it is of course essential to have a certain knowledge of more conventional nuclear-structure physics. Szymański admits that some of the important theoretical ingredients have been treated rather briefly in his Chapter 1. Although this is mitigated to some extent by copious references, the uninitiated will find the book tough going. For those with a reasonable working knowledge of nuclear structure, however, it will be essential reading. □

Neil Rowley is in the Theory and Computational Science Division at the Science and Engineering Research Council's Daresbury Laboratory, Warrington.

Photoreceptors for the beginner

Aubrey Knowles

Photoreceptors: Their Role in Vision.
By Alan Fein and Ete Z. Szuts.
Cambridge University Press: 1983. Pp.212. Hbk £17.50, $34.50; pbk £7.95, $13.95.

OUR knowledge of retinal photoreceptors has increased considerably over the past 20 years, and our present ideas about their function have come from a variety of disciplines ranging from anatomy through chemistry to physics. This book meets a need by providing a comprehensive review at a fairly elementary level. The fact that it appears in the IUPAB Biophysics Series should not put off intending readers: the volume could equally well have been included in a series on zoology or chemistry.

Vision is a sense common to most animals, and it is now clear that the photoreceptors of all species have structural similarities and their visual pigment molecules are closely related. However a gulf exists between workers on the vision of vertebrates and those dealing with invertebrates, due to the different visual characteristics observed and to the use of different techniques. The authors have made a good job of pulling together a wealth of information from these two fields, but this has of necessity involved the critical selection of material.

My principal criticism of the book is of bias in this selection that arises from Drs Fein and Szuts's interest in invertebrate vision. While this may merely reflect my interest in vertebrate photoreceptors, most students take an anthropomorphic view of vision, and can best tackle the subject as an extension of their own experience. The authors recognize this in the introductory chapters, where human visual performance is stressed, but this approach is abandoned as the text develops. In Chapter 8, which covers adaptation, vertebrates are barely mentioned. Cone receptors, colour vision and the visual performance of vertebrates receives poor coverage, although this area is of general interest and is the subject of active current research. The book thus attempts a useful service in bringing together the very different visual characteristics of insects and man, but fails to sustain this approach through to the end.

In another way the balance of the book is also not quite right, the early chapters being cluttered with detail while the later chapters become shorter and more cursory. Much of the early detail is irrelevant and some is contentious — for example, the conjectured sensitizing pigment in fly receptors on p.78 — while recent important work on single cell electrophysiology and the molecular mechanisms of transduction and adaptation are all compressed into the final 30 pages. The references are sensibly arranged at the end of the book and form a useful reading list. Unfortunately this list omits some useful recent reviews and contains a number of outdated and trivial references which will not be helpful to a newcomer to the field.

In summary, the book is a useful addition to the literature of vision, and will be helpful to students and research workers entering the field; I will recommend it to our second-year students in future. It is nicely produced though some of the figures are poor. □

Aubrey Knowles is a Research Fellow in the Department of Biochemistry, University of Bristol.

Adaptive radiation as displayed by Hawaiian sicklebills. The illustration is taken from *Darwin's Finches* by David Lack, recently reissued by Cambridge University Press with notes by Laurene Ratcliffe and Peter Boag. Price is hbk £19.50, $39.50; pbk £7.95, $13.95.

The microfilament system

Uno Lindberg

Mechanisms of Cell Motility: Molecular Aspects of Contractility.
By Peter Sheterline.
Academic: 1983. Pp.180. £14, $23.

RESEARCH on the structural organization of eukaryotic cells in general and cell motility in particular was revolutionized by the development of antibodies against actin by Lazarides and Weber in 1974. Discovery of these antibodies led to a startling new picture of the distribution of actin in different kinds of cells and made it clear that chemo-mechanical transduction by the actomyosin system might be a fundamental process common to all eukaryotic cells. Exciting findings followed rapidly,and within a few years it became evident that eukaryotic cells have a complex and dynamically changing cytoskeleton consisting of finely tuned filament systems (microfilaments, microtubules, and intermediate filaments) through which the life processes can be directed and performed in a precise way. Peter Sheterline's book deals primarily with the microfilament system.

The molecular mechanisms underlying cell motility are still largely unknown. Many proteins which interact with the microfilament system have now been isolated, but the observations concerning their activity *in vitro* give only vague answers to several of the outstanding problems — how microfilaments are formed; how filopodia, microvilli and stress fibres are built by packing of actin filaments in paracrystalline bundles; how membrane lamellae extend themselves from the surface of cells and might cause the observed translocations; and how all of these phenomena are regulated.

When lecturing on these matters I usually begin by describing the diversity of motile activity expressed by eukaryotic cells but emphasize that there might be a common basic mechanism. But to consider this it is necessary to have a relatively detailed picture of the organization of the individual structural elements of different types of cells and the different filament systems. After covering that I explain the difficulties involved in correlating the molecular organization of the cell structure with the behaviour of cells. Only then do I tackle the biochemistry of the components of the filament systems. I feel it is difficult for the beginner to see the molecular details but not lose track of the overall structural organization and behaviour of the cell.

Peter Sheterline has organized his book the other way around. He starts with a thoughtful discussion of the proteins involved in the microfilament system. Then he deals with the ultrastructural organization and with possible mechanisms. One could approach the book by taking a good look at the pictures of cells provided in Chapter 6, and then read Chapters 1–5 to find out more about the proteins involved. Then one might study carefully the concept of "contractile networks", but without taking the different models presented too seriously — they may be far from the reality of the living cell. Unfortunately, the author makes no attempt to tell how the story has developed, and he makes few references to original observations. So while there is something in the book to exercise the specialist, the newcomer should look elsewhere for an introduction to this field. □

Uno Lindberg is a Professor at the Wenner-Gren Institute, University of Stockholm.

Talk of science and philosophy

Donald MacKay

The Philosophy of Popper.
By T.E. Burke.
Manchester University Press: 1983. Pp.220. £6.50, $8.

IN a year that has seen the publication (at last) of Sir Karl Popper's famous three-volume *Postscript* (see *Nature* **300**, 663-664, 1982; **302**, 357-358, 1983), there would be little need for yet another summary of his philosophical position. What Dr Burke has provided (despite his textbookish title) is something quite different. Recognizing that "his own works are by far the best sources of information about the context of [Popper's] thought" (p.vii) he has chosen instead to take some of Popper's key ideas as a starting point for critical enquiries which explore much wider territory. In the process he brings out both the strengths and the weaknesses he sees in Popper's massive contribution to contemporary thinking about the nature of science and scientific reasoning, of human society and human freedom, and indeed of the philosophical enterprise itself.

The book falls into five sections, concerned respectively with the philosophy of philosophy, the philosophy of science, relativism and truth, historicism, and freedom and values. In each, Popper's characteristic emphases are noted, with the help of representative quotations; but on the whole the reader is expected to be familiar with their original context, and to be interested mainly in the way they relate to other strands of contemporary thought.

Popper sees philosophy as a critical or mind-clearing response to crises that arise (typically) in other fields of interest. As such it has genuine problems to tackle; and Popper had no time for the Wittgensteinian idea that its goal should be to dissolve rather than solve them. But what Burke asks is whether, after all, Popper and Wittgenstein had as much to quarrel over as they thought; and he argues that Popper's own philosophizing "can equally well be presented as almost classical examples of Wittgensteinian philosophy". Popper's famous refutation of historicism, for example, "hinges on the claim that, given a sufficiently careful description of the relevant disciplines, and drawing of the demarcation-lines between them, the temptations of historicist programmes disappear" (p.25).

For Popper our main concern, whether as scientists or philosophers, is, or ought to be, the search for truth; no mere instrumentalism could do justice to the drive behind the scientific enterprise. Yet paradoxically he is also famous for the doctrine that though science is seeking truth, it can never have logically sufficient grounds for claiming to have found it. Induction, in particular, he has dismissed as "a myth". Burke, while sympathetic to Popper's reasons for such radical scepticism, argues that "his taste for the dramatic has led him to overstate his case" (p.48). Burke insists that for any serious attack on falsehood or ignorance, we need a basis of established truths, however limited, which can and must be secured in ways that avoid the corrosion of universal scepticism. Without this, he argues, Popper's uncompromising rejection of relativism runs into logical difficulties.

What Popper rejected, of course, was not the principle of relativity as such, but the tendency, especially among social scientists, to turn it into a denial of objectivity. "By relativism", he said, "I mean the theory that the choice between competing theories is arbitrary" (cited on p.82).

Popper's terminology does not make it as clear as he might that a thorough-going relativist can also be a thorough-going objectivist, provided that there are objective transformations linking statements that are valid from different standpoints. Burke, however, goes further and maintains that "there is a case for relativism in the form in which Popper denounces it" (p.86); but the case he makes is not particularly strong.

Scientific theories can indeed be surprisingly resilient in face of contradictory evidence; but this does nothing to justify Feyerabend's claim (cited on p.70) that "we can turn science from a stern and demanding mistress into an attractive and yielding courtesan who tries to anticipate every wish of her lover". It does, however, as Burke points out, tend to soften the sharp epistemic contrast usually drawn by Popperian fallibilists between scientific and metaphysical doctrines.

These examples typify Burke's treatment of his theme — respectful and sympathetic, but refreshingly independent, and eager to report what he can see when standing on the shoulders of his chosen giant. He handles language with a craftsman's skill and precision, and though seldom humorous is never dull. Reading him will be a stimulating experience for anyone who, having absorbed Popper's eloquent message, wonders what remains to be said. □

Donald MacKay is Emeritus Professor of Communication and Neuroscience at the University of Keele.

Planning ahead

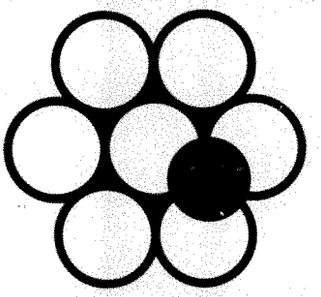
Warren R. Jones

Birth Control Technologies: Prospects by the Year 2000.
By Michael J.K. Harper.
Heinemann Medical/University of Texas Press: 1983. Pp.270. £15, $27.50.

THIS timely and comprehensive volume highlights the salient question surrounding global activities in fertility regulation. The social and personal imperatives for effective family planning are as pressing now as they have ever been, but the strategic priorities remain unclear — whether to concentrate finite resources on improving the distribution and acceptability of existing contraceptive methods, or to promote further research into new technologies.

Contraception research and development has now reached a watershed. In recent years, partly as a result of the economic recession, there has been a relative decline in the funding of goal-orientated research into reproduction. This decline began at a time when at least some new contraceptive techniques had reached a critical stage of development. Further progress will now only be made either by dint of serendipitous breakthrough or by more investment of high-risk capital by international agencies and pharmaceutical companies.

The book is built around Dr Harper's critical perception of the current state of the contraceptive art and of prospects for the practical application of new and improved birth control technologies by the year 2000. Each method — current, new and potential — is comprehensively reviewed and supported by an up-to-date and extensive, though critical, survey of relevant literature. The author's predictions are grouped in temporal categories of implementation: highly likely before 1990; possible, but prospects doubtful by 1990; unlikely before 1990 but possible by 2000. Most promise is seen in the area of female contraception with little to offer for the male. The most likely new technology strategies to reach practical application in the next decade are steroid implants, new injectables, better IUCDs, vaginal rings, prostaglandins for abortion and non-steroidal anti-ovulation agents. The fate of radically superior new methods such as contraceptive vaccines, menses-inducing pills or tampons, and pills or injections for the male is uncertain at present.



All health professionals who are concerned with the control of human reproduction would do well to read *Birth Control Technologies*. It is scientifically impeccable and, at the same time, eminently readable. In some senses, however, it is depressing. Our contraceptive armoury has progressed little beyond modification of steroidal methods, medicated IUCDs and mechanically simplified contraception. The promise of the future is uncertain, but insofar as advances in science are predictable Dr Harper has given us a blueprint for the next two decades and possibly beyond. □

Pharmacia Fine Chemicals

Circle No.21 on Reader Service Card.

The products featured in this week's selection include an air purifier, a refractive index detector and a digital colorimeter

● A new range of all-diffused, fast recovery diodes has been introduced by Westcode Semiconductors. The CXC 924 series is based on 50 mm diameter silicon. It has been developed for use in inverter and chopper circuits. This new diode series is characterized by a repetitive voltage rating of between 1,600 and 2,500 V and an average forward current of 1,265 A at a heat sink temperature of 55°C. Maximum forward current is 2,450 A.
Circle No. 100 on Reader Service Card.

● The Mitsubishi CA-05 moisture meter offers sensitivity to 0.1 μg H_2O. It measures moisture by applying coulometry to the Karl Fischer titration method. The microprocessor controls eight calculation formulae. Samples containing interfering substances and solids insoluble in Karl Fischer reagents are measured by attaching the VA-05 water vaporizer to the CA-05 moisture meter. The VA-05 removes the water from the sample, then transports it to the CA-05 for Karl Fischer titration. The CA/VA combination has a maximum titration speed of 2 mg H_2O min^{-1} and a range of 10 μg to 100 mg H_2O. Precision is ± 5 μg from 10 μg to 1 mg, and 0.5% over 1 mg. A 16-digit alphanumeric display presents calculation results in p.p.m. and percentage H_2O, as well as logging the year, month, day, hour and minute. An integral 20-digit thermal dot matrix printer provides a complete record of calculations.
Circle No. 101 on Reader Service Card.

The CA-05 moisture meter from Mitsubishi can detect 0.1 μg of water.

● A refractive index detector, the SP 6040, is now available from Spectra-Physics. The SP 6040 is a deflection-type differential refractive index detector. Its long focal length increases sensitivity. A temperature control system is built in.
Circle No. 102 on Reader Service Card.

● The 125-test bacteriuria screening kit from Turner Designs is now available from Techmation. The assay is based on the micro-ATP measurement of viable organisms and uses only 50 μl of luciferin-luciferase. The system is claimed to have a false negative rate of around 2% and a false positive rate of 20%. No centrifugation or somatic ATP extraction is required. The model 20 can be used with both the new Turner Designs kit and with most *in-vitro* diagnostic kits.
Circle No. 103 on Reader Service Card.

● The Rodwell Ensign is a free-standing, vertical-loading autoclave with a chamber space of 100 litres. The system does not have to be 'plumbed in', which means that installation only requires an electrical supply. Water that has condensed from the chamber is collected through an integral catchment system. This minimizes water consumption and removes the need for drains and collection vessels.
Circle No. 104 on Reader Service Card.

● Romicon has developed a system for the treatment of water and other fluids before reverse osmosis. The Romicon RO treatment system has wide channel tubes, hollow fibre membranes and operates in a shell and tube geometry at low pressures. It has membrane filters of approximately 0.005 μm.
Circle No. 105 on Reader Service Card.

● An analog multiplexing system is now being produced by Ancom. This DAM (distributed analog multiplexer) system uses a four-wire transmission system and consists of two basic components — a central controller/interface card and a series of remote transmitters. The transmitters accept inputs from transducers such as temperature, humidity, pressure and flow sensors, using local signal conditioning. The Ancom system is controlled through the DAM-C1 card, which can be connected to a thumb-wheel switch and digital display or a microcomputer. The switch is used to select the desired input channel and information is then displayed on the digital readout. A further output connection is available. The four-wire analog transmission system can be up to 1 km in length.
Circle No. 106 on Reader Service Card.

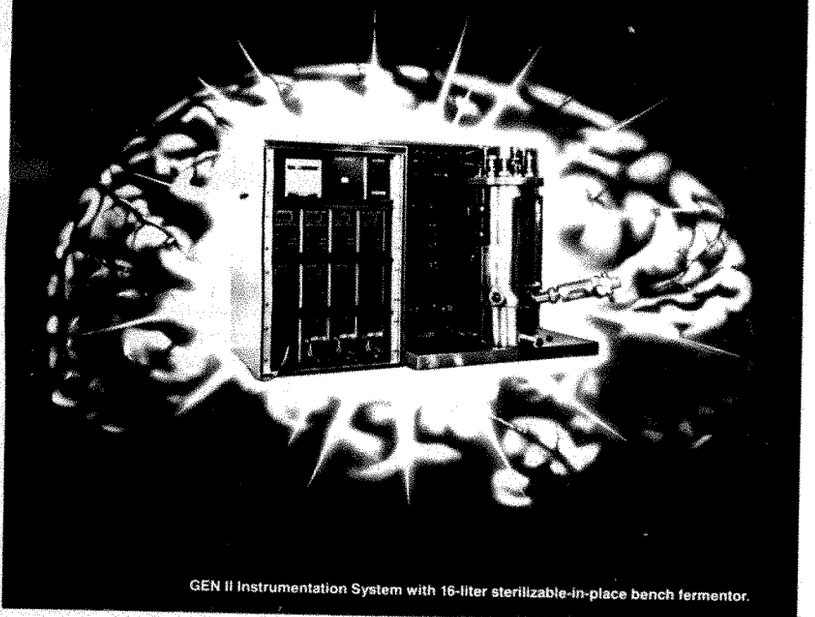
● Micro Instruments has produced a glass microelectrode puller. This new vertical puller is an automatic double-pull type which will take 1 to 4 mm diameter glass tubes. The setting controls allow the heat and the magnets for the initial and the second pull to be adjusted, depending on the thickness of glass tubing being used. Further adjustments are provided to control the heating off time and the pulling time. The glass tubing is held in chucks that are controlled by a 'one-touch' clamping device. The instrument is supplied with a range of chucks and heater coils.
Circle No. 107 on Reader Service Card.

● Astell Hearson has increased its Swiftlock range of autoclaves with the new Swiftlock series 3000. These autoclaves are designed to enable processing of both media and discard material. Three independent adjustable programs are selectable from the front panel and all adjustable controls including a fault reset button are beind a lockable, perspex panel. Supercool models are also being produced.
Circle No. 108 on Reader Service Card.

● Jenway has developed a new digital colorimeter. The Jenway PC01 colorimeter operates in three measurement modes: transmittance, from 0 to 100%, to a resolution of 0.1%; absorbance, which is electronically linearized, from 0 to 1.999 to a resolution of 0.001; and two concentration ranges which provide coarse and fine measurements over the absorbance readings. In this mode the instrument, using most methodologies, provides a direct reading of solution concentration. The PC01 is supplied with eight integral filters to cover the wavelength range 400 to 710 nm. The instrument's bandpass is typically 40 nm.
Circle No. 109 on Reader Service Card.

● A catalogue of specialized equipment for rodent research is now available from Harvard Bioscience. Areas covered in the catalogue include respiration, animal surgery, and housing.
Circle No. 110 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.



● A new range of Mystaire ward and laboratory air purifiers is now available from Heat Systems Ultrasonics. Interchangeable packs of chemisorbents, activated charcoal and impregnated charcoal are used in conjunction with standard mechanical filter packs to remove specific airborne contaminants.
Circle No. 111 on Reader Service Card.

● Racal Safety has added a power-assisted respiratory system to its Dustmaster series. The Dustmaster 7 includes a mask weighing 50 g with all-round vision. The mask receives a clean air supply through a hose attached to a belt-mounted motor/fan filter.
Circle No. 112 on Reader Service Card.

● Horwell's new Accusplit 920 XP digital LCD quartz wrist watch offers several scientific functions. The countdown timer, pre-settable up to 15 h 59 min, sounds an alarm for 5 s on expiry of the countdown period. Its time-of-day alarm sounds when the pre-set alarm time is reached, but a day exclusion facility stops the alarm going off on days when it is not required. The stopwatch facility times up to 12 h, unless previously stopped, in minutes, seconds and one hundredths of a second up to 20 min and thereafter in hours, minutes and seconds. The watch also tells time of day to the nearest second along with month, date and day of the week. There is an optional hourly bleep.
Circle No. 113 on Reader Service Card.

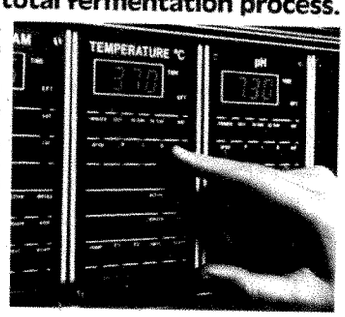
Why buy a "dumb" fermentor when you can have an intelligent fermentation system for the same price

GEN II Instrumentation System with 16-liter sterilizable-in-place bench fermentor.



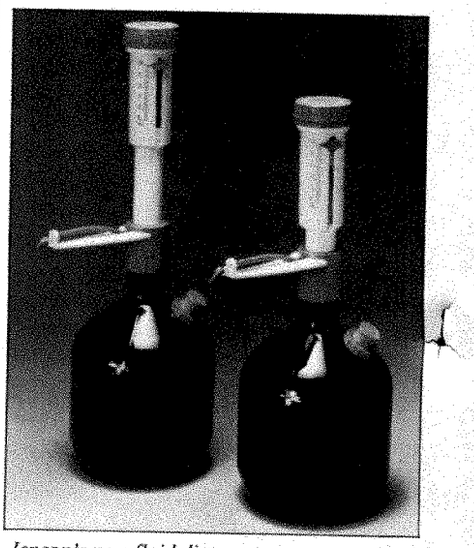
Now! Microprocessor-controlled instruments "talk" to each other to provide interactive control of the total fermentation process.

You don't pay for software and you don't pay for a computer interface — NBS includes them in every instrumentation system.

GEN II is used with bench-top, pilot plant and production fermentors to provide a variety of control strategies including time-based and event-based profiling.

Individual instruments have full PID control capability with proportional gain, as well as integral and derivative time adjustments. The system incorporates fully distributed control and manual back-up of every parameter.

With GEN II, any fermentor has the brainpower it needs for super sophistication and reliability. And, if you can operate your calculator, you can operate GEN II. Send for our new 84 page Fermentation Catalog at P.O. Box 986, Edison, N.J. 08818 or call 800-631-5417.



NEW BRUNSWICK SCIENTIFIC CO., INC.
At NBS Advanced Technology is a Way of Life

● Matheson has produced a new electro-pneumatic system that will automatically purge hazardous gas systems. The system is microprocessor-controlled so that valve sequence, number of purge cycles and cycle time can be programmed. The system also responds to pressure, confirmation of valve operation and completion of previous operations. The controller features a shutdown mode in which all valves close when there is a power failure or electrical component malfunction. The purging hardware portion of the system can be up to 200 feet from the controller. The system uses pneumatically-activated Matheson Packless valves which will operate against a cylinder pressure of 2,500 p.s.i. in either direction.
Circle No. 114 on Reader Service Card.

● A fully-automated cassette-to-cassette reactive ion etching system has been introduced by Intertrade Scientific. The LFE Autohex system is equipped with load-lock capability and has been shown to increase throughput and repeatability by 50% compared with manual hex systems. The load-lock is designed to reduce contamination in the process chamber. Operators are not exposed either to the etching gases in the chamber or to residual gases during tray-loading and unloading. A simplified control panel for the system is available from ITS for routine daily operations.
Circle No. 115 on Reader Service Card.

● Jencons Scientific has developed a new duo-style range of fluid dispensers. These models are adapted from Jencons' Zippette and incorporate two types of dispenser. The first is a semi-automatic spring loaded dispenser which refills itself following each delivery. The second is used without the actuator piston spring as a manual model. The duo-style safety Zippette covers the 5 ml, 10 ml, 30 ml and 50 ml range. The MK IV Zippette will dispense acids, aggressive liquids and organic solvents.
Circle No. 116 on Reader Service Card.

Key skills and employment growth

Richard Pearson*

For countries left behind by the rapid progress in electronics, prospects for employment will be poor.

THE electronics market is very competitive and is being increasingly dominated by US and Japanese producers, with the Europeans coming a poor third. For example, more than half the world's semiconductor market is supplied by ten companies, five American, four Japanese and one European.

The race is now on for the "fifth-generation computer", and with increasing technical and product integration, "chips" and their derivatives are playing an increasingly critical role in the development of the electronics, manufacturing and service industries. While the semiconductor industry is important in its own right, with world sales of well over $15,000 million a year and a workforce of about 250,000 (Fig.1), the dependent electronics-related markets are of course far bigger, employing several million people.

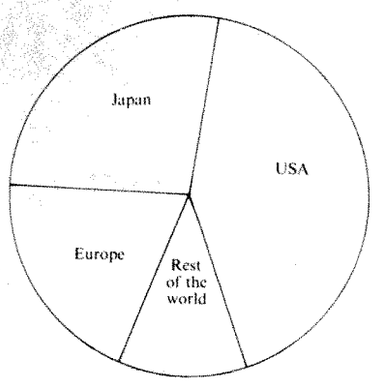

Fig. 1 Manpower in the semiconductor industry. (Institute of Manpower Studies estimates.)

Although the semiconductor industry is particularly sensitive to the economic cycle, it is now experiencing a sharp upturn, and all the forecasters agree that demand will grow significantly in the long term, with output possibly doubling by the end of the decade. Success in these microelectronics markets means large numbers of jobs in the future, yet their success will be critically determined by the availability of a few thousand people with key skills today.

In California, in "Silicon Valley", the birthplace and home of the industry, the companies see two chief threats, growing Japanese competition and shortages of skilled manpower. The recent US Office of Technology Assessment (OTA) report (*Nature* **306**, 307; 1983) may have helped to put the general Japanese threat into perspective but the problems of recruitment are ever present and expected to get worse. In "Silicon Valley", crowded conditions, soaring house prices, rising compensatory salary levels and an inability to attract sufficient skilled staff are leading the major producers to consider moving their factories elsewhere both in the United States, in areas such as Colorado and Austin, Texas, and also in Europe with its rapidly growing semiconductor market.

Semiconductor manufacturers everywhere are struggling with a shortage of key skills and the need to develop a pool of appropriately experienced staff for the future. Thus while an electronics engineer or designer may be highly productive at the relatively young age of 24 or 25, much of his or her necessary experience will have been developed in the two or three years spent in the industry after graduation. Many of the more general skills are interchangeable with the electronics industry, enabling a new or rapidly expanding company which pays top salaries to "poach" experienced staff from a wider pool. However, in the more specialized areas of circuit design, such as very-large-scale integrated circuit (VLSI) design and in process engineering (that is, managing the production line), such skills are only developed on the job, in a semiconductor company. The high costs of equipment and the need to reinvest every three to five years preclude higher education, for example, from contributing effectively to the future supply of experienced people through undergraduate and postgraduate education.

Given the small numbers with such skills, fewer than 2,000 in Europe for example (Fig.2), there are great advantages for semiconductor companies in "clustering" together, facilitating an interchange of skills. This also helps in recruiting staff who can change jobs without relocating. Much of the success of Silicon Valley is put down to the rapid interchange of staff between companies and general ease of career mobility. Such clusters occur "spontaneously", as in California, along Route 128 in Boston, and along the M4 in England. They can also be encouraged by intervention as in Scotland, which is now, through inward investment, a major world electronics centre. Indeed the Scottish Development Agency is capitalizing on this ease of job changing and career development in a small area as part of its recruitment campaign to attract electronics skills to Scotland.

The electronics and related industries are seen as one of the few certain growth sectors for the future. Most governments are therefore encouraging the development of their indigenous industries and are seeking to attract "inward investment" by electronics-based companies. Advances in automation mean that much of the growth in output is being matched, and sometimes overtaken, by increasing productivity levels. The absolute number of assembly and less skilled jobs may well shrink in the future, but the demand for key skills will continue to grow. With up to 10 or more other jobs in the industry, and many more outside it, dependent on each skilled job, the availability of key skills will continue to have a disproportionate effect on attracting and expanding employment in a particular locality.

For many of these skills, semiconductor companies can look to the much wider electronics industry and, provided it can offer attractive salaries and conditions, employers should be able to buy their way out of problems. However, in terms of the few thousand staff needing industry-specific skills, such as VLSI design and process engineering, relevant experience, which can only be acquired in the industry, is critical. Given the long lead times involved in gaining such experience, how will the supply be increased to meet the growing needs of the future? With shortages of skilled staff already apparent, will market forces work resolve these mismatches or will manpower availability and constraints help to determine the industry's winners and losers, and hence the prosperity of particular localities over the next decade? □

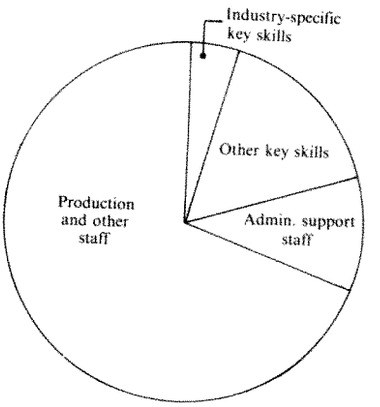

Fig. 2 Balance of skills in European industry.

UNIVERSITY OF CALIFORNIA, BERKELEY

DEPARTMENT OF ASTRONOMY AND ASTROPHYSICS

ADJUNCT ASSISTANT PROFESSORSHIP

Pending final budgetary approval, the Department of Astronomy of the University of California at Berkeley expects to make one non-tenure track appointment renewable up to five years in astronomy/astrophysics at the Adjunct Assistant Professor level, which can start as early as July 1, 1984. Applicants should send a curriculum vitae, bibliography and a brief statement of research interests, and should arrange to have three letters of recommendation sent to Jonathan Arons, Chairman, Search Committee, Department of Astronomy, University of California, 601 Campbell Hall, Berkeley, CA 94720. All materials should be received by February 1, 1984.

The University of California is an Equal Opportunity, Affirmative Action Employer. (NW181)A

CHARING CROSS HOSPITAL MEDICAL SCHOOL

(University of London)

SENIOR LECTURER IN BIOCHEMISTRY

Applications are invited for the above post. Candidates should have significant, relevant teaching experience including postgraduate training, and have established themselves as independent scientists as shown both by published work and by ability to attract external funding. They will join the Gene Structure and Function Group being established by A D M Malcolm from whom further particulars may be obtained (address below; telephone 01-748 2040 ext 2835).

Applications (two copies) naming three referees should be sent as soon as possible to The Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St Dunstan's Road, London W6 8RP. (905)A

THE UNIVERSITY OF BRITISH COLUMBIA

GRADUATE STUDIES IN CHEMISTRY

Applications are invited from candidates with high academic records who wish to pursue further studies towards the MSc and PhD Degrees in Chemistry. Excellent research facilities are available in all areas of modern Chemical Science, ranging from Biological Chemistry to Chemical Physics. Teaching and research assistantships are available for all students in the programme. Stipends up to $20,800 are available to highly qualified students who hold scholarships; the minimum stipend for 1983/84 is $11,000.

Application forms and further particulars may be obtained from: Dr L Weiler, Professor and Head, Department of Chemistry, The University of British Columbia, 2036 Main Mall, Vancouver, BC, Canada V6T 1Y6. (NW773)A

UNIVERSITY OF LEICESTER

MEDICAL SCHOOL
DEPARTMENT OF SURGERY

NON-CLINICAL LECTURESHIP

Applications are invited from non-medical scientists for a post of Lecturer in the Department of Surgery. Candidates should be post-doctoral and previous experience in tissue culture and immunology would be helpful.

Initial salary will depend upon qualifications and experience on the Lecturers' Scale £7,190 to £14,125.

Further particulars from the Registrar, University of Leicester, Leicester LE1 7RH, to whom applications should be sent on the form provided by 26 January 1984. Informal enquiries may be made to Professor P R F Bell, Department of Surgery, Clinical Sciences Building, Leicester Royal Infirmary, PO Box 65, Leicester (telephone: (0533) 551234 ext 429). (914)A

British Museum (Natural History)

Geochemist

The British Museum (Natural History) is primarily an institution for taxonomic research and has world-wide collections of animals, insects, plants and minerals. There are 5 scientific departments which are supported by a comprehensive library and full technical services including electron microscope and computer facilities.

This opportunity is in the Department of Mineralogy which is well equipped for the analysis of minerals, rocks and meteorites by classical and by instrumental methods. The successful candidate will assist in the running and development of the electron microprobe facility and other instrumental techniques such as neutron activation analysis, particle track analysis and X-ray fluorescence. Duties will also include service analyses by instrumental methods, collaboration in team research and the preparation of rock, mineral and standard samples for analysis.

Candidates should have a good honours degree in chemistry or geology or both; post-graduate experience in mineral chemistry or geochemistry advantageous.

Appointment as Scientific Officer £6930-£9015 (including £1250 Inner London Weighting) with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 27 January 1984) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). (896)A

RECHERCHE

VETERINAIRE CLINICIEN ET CHIRURGIEN EXPERIMENTE

Adjoint au Responsable de son Centre de Primatologie

FONCTIONS

* Surveillance sanitaire et soins aux primates et autres animaux de Laboratoire.
* Participation aux différents protocoles de recherche en cours, basés principalement sur la Biologie de la Reproduction.
* Participation à la Gestion du Département.

Excellentes conditions de travail.
Contrat début avril 1984 pour 2 ans renouvelables.
Conditions habituelles d'expatriation.

Candidatures à adresser à Monsieur le Directeur Général du CIRMF, 28, Bd de Grenelle, 75015 PARIS, avec Curriculum Vitae, références professionnelles et prétentions. (W620)A

Universiteit van Amsterdam

The Subfaculty of Biology invites applications for a:

visiting professorship in environmental biology (m/f)

with responsibility for teaching and research in environmental biology and for co-ordination of teaching courses leading to professional qualification in Biological Management.

The most important task of the successful candidate will be the integration and co-ordination of current teaching and research in fields related to environmental biology with the goal of creating a unified programme for a new workgroup in Environmental Biology (ex.art. 18 - W.U.B.).

Candidates should hold a Ph.D. degree and posses proven research and teaching ability in environmental biology, in particular in the area of aquatic management. He or she should display good organizational and social qualities and have experience in leadership of a research team. The successful candidate will be expected to make a major contribution to the administrative management of the workgroup, and to establish and maintain contact with other groups working in similar fields.

Appointment to the position will be for a period of 2 years. Part-time appointment is also possible, but full time is prefered.
Salary max. Dfl. 9,283.- per month
(Dutch Civil Servants Code).

Applications, together with a curriculum vitae, list of publications and references, should be sent - within 1 month - quoting number 7389 to the Chairman of the Appointment Committee, Dr. S. Pinkster, Vakgroep Bijzondere Dierkunde, P.O. Box 20125, 1000 HC Amsterdam.

Suggestions for possible candidates may be sent to the Committee.

Woman in particular are invited to apply.

(W624)A

SENIOR ORGANIC GEOCHEMIST

Division Head Required for Interdisciplinary Exploration Team

Woodward-Clyde Oceaneering, an expanding International Geological consulting firm based in Aberdeen, invites applications from individuals with a PhD Degree and a minimum of five years experience in Petroleum Geochemistry. Responsibilities will include developing and managing geochemical hydrocarbon exploration programmes in frontier basins, both terrestrial and marine, utilising current theories in organic geochemistry. Knowledge of a variety of instrumental methods such as GC, GC/MS, Fluorescence, Pyrolysis and Isotope Ratio/MS is desirable.

This position provides the opportunity of working with a multi-disciplinary exploration team consisting of Geologists, Geophysicists and Engineers. Résumés will be treated confidentially. Please state availability. The successful candidate would be expected to assume duties in March/April 1984.

Salary will be negotiated within the range of £15,000 to £22,500, to be commensurate with experience. Interviews will be scheduled in London and Aberdeen during the week of 30 February 1984. Reply to Box No 925 c/o Nature, 4 Little Essex Street, London WC2R 3LF.

(925)A

PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS Centre for Applied Microbiology and Research
MICROBIAL TECHNOLOGY LABORATORY
POST-GRADUATE BIOCHEMIST

To evaluate novel support matrices for the large scale affinity chromatography of proteins. This post is sponsored by the Engineering Sciences Division of AERE Harwell under the auspices of the BIOSEP project, and is available for one year in the first instance. Applicants should have a PhD or an equivalent research qualification. Experience in the purification of proteins on a larger than normal laboratory scale and some understanding of the engineering aspects of large scale chromatography is desirable.

Appointment, subject to qualification and experience will be made on the post-probationary basic grade scale, £6520—£8349. NHS terms and conditions will apply. Applications with full curriculum vitae and the names and addresses of two professional or academic referees should be sent to:
Mrs M Bushby, Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wiltshire.

Candidates seeking further information should contact Dr M Scawen on Idmiston (0980) 610391 extension 220.

Closing date for applications will

THE UNIVERSITY OF LEEDS

DEPARTMENT OF EARTH SCIENCES

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post for work on the seismicity and structure of the Cameroon Volcanic Line involving the installation and maintenance of a seismic telemetered network in SW Cameroon and gravity mapping the volcanic province in collaboration with the Institute of Geological and Mining Research (Cameroon). The appointment will be made for a fixed period of up to two years from 1 April 1984. Applicants should have a good honours degree in Geology, Geophysics or Physics and should have or shortly expect to receive a PhD in Geophysics preferably Seismology.

Salary on the IA Range for Research and Analogous Staff (£7,190 — £11,615), according to age, qualifications and experience.

Informal enquiries may be made to Professor Briden (telephone (0532) 431751 ext 6415).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT quoting reference number 49/25/D, to whom applications should be addressed. Closing date for applications 8 February 1984.

Applicants from overseas may apply in the first instance by telex (556473) or telephone (0532) 431751

FACULTY POSITION AVAILABLE

The Department of Earth, Atmospheric, and Planetary Sciences of the Massachusetts Institute of Technology is seeking to appoint a physical oceanographer at the Assistant Professor level. Candidates will be considered from any area of physical oceanography, but the department is particularly interested in developing its programs (both theoretical and observational) in large-scale, deep-sea, physics. Individual chosen would be expected to carry on a vigorous research program and to teach graduate level courses in physical oceanography. Will be a member of the Center for Meteorology and Physical Oceanography.

Please submit a résumé, publication list, statement of interests and names of three references to: W F Brace, Chairman, Dept. of Earth, Atmospheric, and Planetary Sciences, 54-916, MIT, Cambridge, MA 02139.

MIT is an affirmative action/equal opportunity employer. (NW171)A

UNIVERSITY OF PRINCETON

DEPARTMENT OF BIOLOGY

NEUROBIOLOGY

The Department of Biology wishes to appoint one or more neurobiologists. The level is flexible and we are particularly interested in someone working in molecular or cell biological areas of neurobiology. Please write to J.T. Bonner, Chairman, Department of Biology, Princeton University, Princeton, N.J. 08544.

Princeton University is an Equal Opportunity/Affirmative Action Employer. (NW178)A

ROYAL POSTGRADUATE MEDICAL SCHOOL

(University of London)

DEPARTMENT OF CLINICAL PHARMACOLOGY

SENIOR RESEARCH OFFICER

A postdoctoral person with experience of protein chemistry is required to join a multi-disciplinary team involved in the purification and characterization of human hepatic cytochromes P-450. The project will involve structural analysis of proteins by biochemical and immunological techniques. The post is supported for a period of 5 years with a salary in the range of £7,190 to £11,615 plus £1,186 London Allowance a year.

Further details of the research programme may be obtained from Professor D S Davies or Dr A R Boobis (Tel: 01-743 2030 ext 454).

Application forms may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0HS, quoting reference 20/104/N.

Closing date: 26 January 1984. (910)A

ST JUDE CHILDREN'S RESEARCH HOSPITAL

St Jude Children's Research Hospital is seeking investigators doing innovative research in the areas of contemporary cell or molecular biology to join the faculty in the Divisions of Human Tumor Cell Biology (2 positions) and the Division of Pathology (1 position). Appointments will be at the Assistant or Associate Member level, depending on qualifications and experience, and are intended for individuals interested in investigator-initiated, full-time research. Applicants should have the minimum of two years post-doctoral experience and potential or demonstrated ability to conduct an independent program. Send CV and names of three references to: Charles J. Sherr, M.D., Ph.D. Chairman, Search Committee St Jude Children's Research Hospital Division of Human Tumor Cell Biology 332 N. Lauderdale Memphis, Tennessee 38101

St Jude Children's Research Hospital is an affirmative action employer. (NW173)A

INSTITUTE Of Cancer Research, Cell Transformation Group, Research Officer. Applications are invited for the post of Research Officer in the Section of Chemical Carcinogenesis, working within an established team on the genetic basis of malignant transformation. The work will involve the use of recombinant DNA techniques and eukaryotic gene transfer methods to study the role of dominantly acting transforming genes in the multistage transformation process. Applicants should possess a degree in a biological science plus a minimum of two years relevant laboratory experience, preferably involving some aspect of gene manipulation. At present the laboratories are situated at Chalfont St Giles, Bucks, but will be moving to Fulham Road, London in about six months time. Starting salary will be in the range £6,204 pa — £8,126 pa. Applications in duplicate with the names of two referees to the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref 301/B/42. (904)A

POSTDOCTORAL Research Associate. Position open for recent PhD with strong background in molecular biology, biochemistry or cell biology to study DNA damage and repair in human skin, as part of an ongoing collaboration with investigators at the Department of Dermatology, Harvard Medical School, and Skin and Cancer Hospital, Temple University. The successful candidate will be expected to travel occasionally for experiments at these institutions. Initial appointment is for one year beginning on or about March 1, 1984, at a salary of $17,000 per year minimum. Send vita and names of three referees to: Dr Betsy Sutherland, Biology Department, Brookhaven National Laboratory, Associated Universities, Inc., Upton, L I, New York 19973. EOE m/f. (NW182)A

CSIRO

Research Fellows (2 Positions)

$A24,344 — $A35,806

Division of Chemical Physics

Clayton VIC and Lucas Heights NSW — Australia

CSIRO conducts scientific and technological research in Laboratories throughout Australia and employs about 7,500 staff of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Chemical Physics is a Division of the Institute of Physical Sciences.

General: The Division of Chemical Physics is principally located at Clayton, Victoria, with a smaller unit at Lucas Heights, New South Wales. The Division prosecutes a broad programme of research in chemical physics, using fundamental methods. Presently there are twelve sections: atomic, mass and molecular spectroscopy (including specialized optics), electron microscopy, electron diffraction, x-ray diffraction, computing, theoretical chemistry, theoretical physics, crystal defect physics, radiation effects (including radiation chemistry and ion implantation), solid state science, surface science, and instruments and engineering services. Divisional research objectives are both fundamental and applied.

Position 1: No. A2485

Field: Ion Implantation into Solids.

Duties: The appointee will undertake research into ion implantation of semiconductors for microelectronic device fabrication, and ion implantation of metals for enhancement of surface properties, emphasis being placed on the development of an understanding of the detailed processes involved and of their practical applications. The successful candidate will be located at the Division's laboratories at the Lucas Heights Research Laboratories near Sutherland, New South Wales.

Qualifications: A PhD or equivalent qualifications in Physics or a related field together with an ability to undertake independent scientific research. Experience in surface physics and/or ion beam technology is essential.

Position 2: No. A2658

Field: Electron and Ion Physics.

Duties: The Radiation Effects research group at the Division's main David Rivett Research Laboratories, Clayton, Victoria, is involved in part with research and development and the innovative projection of new and sophisticated devices and methods in 'chemical analysis by mass spectrometry'. Current work includes the development of high efficiency ion sources, magnetic momentum analyzers, electrostatic ionic-mass filters and secondary electron multiplier ion detectors. A new surface analysis technique employing secondary ion mass spectrometry is also under investigation.

The successful appointee to this position will be expected to participate in these experimental research activities at the Clayton site, to assist in developing and applying numerical (computer) methods for field determinations and trajectory tracing and, specifically, to take a leading part in the evaluation of devices in the vacuum physics laboratory. The candidate will be expected to be largely responsible for the technology transfer of devices developed successfully in the Division to the appropriate Australian Industry.

Qualifications: A PhD in physics or chemistry or equivalent qualifications in a related field together with an ability to undertake independent scientific research. Some experience or an interest in electron-optical devices would also be desirable.

Tenure: Both positions are offered for a fixed term of 3 years. Australian Government superannuation benefits are available.

Applications: Stating full personal and professional details, the names of at least two referees and quoting the relevant reference number should be directed to: The Chief; CSIRO Division of Chemical Physics; PO Box 160, CLAYTON Vic 3168, AUSTRALIA. By February 3, 1984. (W621)A

POSTDOCTORAL TRAINING PROGRAM

Three postdoctoral positions will be available, commencing July 1, 1984, at Michigan State University in an NIH supported training program in the combined fields of pathology and environmental toxicology. Applicants should have a DVM, MD or DO degree and be willing to undertake training leading to a dual PhD in Pathology/Environmental Toxicology. Deadline for applications is March 1, 1984. Stipends will be based on NIH postdoctoral levels. More complete description of the program is available upon inquiry.

Please address letters of application with three letters of reference to: Dr. R. W. Leader, Associate Dean, Program Director, College of Veterinary Medicine, A-136 East Fee Hall, Michigan State University, East Lansing, Michigan 48824.

MSU IS AN AFFIRMATIVE ACTION/ EQUAL OPPORTUNITY INSTITUTION. (NW118)A

Consultancy

Nutritional Supplements

The Committee for Responsible Nutrition comprises manufacturers of nutritional supplements who believe that there is a national need for responsible communication on health and nutrition. They, therefore, wish to retain a Consultant on a part-time basis who will:

- advise the Committee members on scientific and medically-related matters concerning vitamin and mineral supplementation
- inform consumer groups, government officials, parliamentarians, retailers and others about new developments within the Committee's sphere of interest
- become a source of expertise and focal point for media contact on nutritional issues as they relate to personal healthcare

An average of 12 to 15 hours per week will be required to be devoted to consultancy duties for which a retainer of around £7,000 p.a. plus expenses will be paid. The work may be done from an existing home or office base provided this is within relatively easy access of Surrey.
The successful applicant should have a genuine personal interest in nutritional supplementation and ideally possess a medical qualification or a PhD in a medical or nutrition-related science. He/she will probably be in his/her thirties with a proven record of success in their chosen field. Suitable experience would include research/university teaching or scientific journalism.
Interested persons should write to:

The Secretary, The Committee for Responsible Nutrition, 7a Church Street, Esher, Surrey KT10 8QS.

(929)A

THE UNIVERSITY OF MELBOURNE

SCHOOL OF PHYSICS

RESEARCH FELLOW (GRADE 2) (TEMPORARY)

The Australian Research Grants Scheme has funded a Research Fellowship for work with Professor B H J McKellar on the project "The Potential Approximation in Nuclear Physics".

Applicants should have a PhD in theoretical physics with a good background in quantum field theory. An appointment may be made for up to three years.

Enquiries should be directed to Professor Mckellar, School of Physics (03) 341 5122.

Salary up to $A26,540 per annum within the range $A23,394 to $A30,734 per annum. A contribution towards the cost of travel to and relocation in Melbourne may be made to an appointee from interstate or overseas.

Further information regarding conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, Parkville, Victoria, Australia 3052, or the Association of Commonwealth Universities, (Appts) 36 Gordon Square, London WC1H 0PF.

Applications close on 29 February

UNIVERSITY OF PITTSBURGH ASSISTANT PROFESSOR OF PHYSICS

A tenure track position as assistant professor in experimental atomic physics will be available starting either in September 1984 or September 1985. Current activities in this area here at the present time include atomic collisions with emphasis on excitation transfer (M A Biondi, R Johnsen), the study of Rydberg atoms and multiphoton effects in atoms (J E Bayfield), and the study of stratospheric processes with laboratory measurements of related cross-sections (E C Zipf). There is theoretical work on collisions (J N Bardsley), high energy radiative proceses (R H Pratt) and multiphoton processes (P Stehle). Preference will be given to candidates whose work would relate to the activities mentioned or to space physics or astrophysics. Credentials should indicate a high promise of establishing a strong research program in atomic physics.

Letters of application, résumés, statements of research interests, and the names of three professional references should be sent to the Chairman, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260. The university is an equal opportunity/affirmative action employer.

(NW120)A

UNIVERSITY OF WASHINGTON PROTEIN BIOCHEMIST

Assistant Professor, Department of Pathobiology with potential joint appointment in Department of Biochemistry, University of Washington, Seattle. Seeking applicant with strong academic credentials to join biomedical research team involved with the biochemical, genetic, and immunochemical characterization of relevant proteins of microbial and protozoal pathogens. Well-equipped laboratory, start-up funds, and competitive salary available.

Position available by March 1984 or thereafter.

Send curriculum vitae, bibliography, and three references to Dr Thomas M Buchanan, Immunology Research Laboratory, 11th Floor, Pacific Medical Center, 1200 12th Ave South, Seattle, WA 98144, USA.

The University of Washington is an Affirmative Action/Equal Opportunity Employer.

(NW159)A

UNIVERSITY OF WYOMING

BIOCHEMISTRY DEPARTMENT

POST-DOCTORAL AND PRE-DOCTORAL POSITIONS

Positions available to investigate biosynthesis of peptide hormones in adrenal medulla and human small cell carcinoma.

Facilities include HPLC's, gas-phase sequencer, cell culture, and RIA, etc. Growing, dynamic, young department located in beautiful mountain surroundings.

Training in chemistry or biochemistry required. Experience in protein chemistry or cloning required for postdoctoral position.

Send résumé and three reference letters to Dr Randolph V Lewis, Box 3944 University Station, Laramie, WY 82071. (NW164)A

IGNEOUS/METAMORPHIC PETROLOGIST

This is a new faculty position, 12-month appointment, tenure-track. Candidate is expected to develop a strong research program, applying theoretical, experimental, and/or latest analytical methods to petrological problems, particularly those related to the origin and evolution of oceanic crust, islands, and/or volcanic arcs. Research experience with one of the following is desirable: XRF, XRD, stable isotopes (O, N, S), solid source mass spectrometry (Sr, Pb, Nd). Rank is Assistant/Associate Professor. Salary is $27,000 — $43,000, commensurate with experience.

Send résumé and names of three references by 1 March 1984 to: G Ross Heath, Dean, College of Oceanography, Oregon State University, Corvallis, OR 97331.

Oregon State University, an Affirmative Action/Equal Opportunity Employer, complies with section 504 of the Rehabilitation Act of 1973.

(NW160)A

THE UNIVERSITY OF ROCHESTER

SENIOR DEVELOPMENTAL PSYCHOLOGIST

The Department of Psychology of the University of Rochester is seeking a distinguished research-oriented developmental psychologist to direct its program in developmental psychology. Close ties with the Graduate School of Education and Human Development and the Department of Paediatrics bring together a group of nine developmental psychologists. The department, consisting of 23 faculty, has several developmentally related research programs, including clinical, social, cognitive science, developmental neurobiology, and visual science. The specific area of the candidate is not as important as an active program of research.

Interested persons should forward a curriculum vitae, the names of five individuals who would write letters of reference, and reprints of representative publications to Walter Makous, Chair, Developmental Search Committee, Department of Psychology, University of Rochester, Rochester, New York 14627. For questions about the position, please call (716) 275-2460. The deadline for receipt of applications is January 30 1984, although outstanding applications may be considered after this date.

The University of Rochester is an equal opportunity/affirmative action employer. Applications from women and members of minority groups are therefore especially welcome. Salary and fringe benefits depend upon the applicant's experience and are competitive.

(NW152)A

UNIVERSITY OF WALES

Welsh National School of Medicine

DEPARTMENT OF MEDICAL BIOCHEMISTRY

RESEARCH OFFICER

A graduate in biochemistry or a related subject is required for a three-year MRC-funded project to work on the mechanism of toxicity of poly-halogenated aromatic hydrocarbons. The project involves the use of immunochemical, radiochemical and h.p.l.c. techniques to investigate the effect of these agents on haem biosynthesis at the molecular level. The opportunity exists for registration for a higher degree.

Commencing salary £6,310 per annum on the scale for University Research and Analogous Staff Grade 1B.

Further particulars and application forms (quoting Ref. No. C38/4/48) available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN (0222/755944 Ext. 2296). Closing date for application: 31st January, 1984.

(944)A

POSTDOCTORAL POSITIONS IN CELLULAR AND MOLECULAR BIOLOGY

are available as early as 1 January 1984. Applicants should have a PhD or MD degree with a background in biochemistry, cell biology, or molecular biology. Specific projects include the following: (i) to determine the nature and regulation of subcellular organelle traffic involved int he endocytosis of insulin and other ligands [Dr. Fine and Dr. Pilch; see J. Cell Biol. 96, 133 (1983)]; (ii) to determine the role of growth factor receptor kinases (insulin and IGF-1) in the regulation of cellular metabolism, receptor metabolism, and/or cellular growth [Dr. Pilch, see Biochemistry 22, 717 (1983) and Nature (London) 305, 438 (1983)]; (iii) to clone the insulin receptor and clathrin genes [Dr. Farmer, Dr. Fine, and Dr. Pilch); (iv) to study the regulation of tubulin gene expresion using ß tubulin cDNA clones (Dr. Farmer, see Mol. Cell. Biol. 3, 1333, (1983)]. Applicants should indicate interest in a specific project and send curriculum vitae and the names of three references to one of the following individuals: Dr. Stephen R. Farmer, Dr. Richard E. Fine, Dr. Paul F. Pilche, Department of Biochemistry, Boston University School of Medicine, 80 East Concord Street, Boston, Mass. 02118. An Equal Opportunity Employer, M/F. (NW155)A

The Biotechnology department of Ciba-Geigy Basle has just completed the construction of a new Research Building. In view of our expanding research activities in Biotechnology we now have some

Postdoctoral Positions

open. The duration of the assignments, which are for highly qualified PhDs with research experience in microbial genetics, rDNA technology, cell biology or protein chemistry, will be 1-3 years. Eukaryotic cell transformation, cDNA cloning, heterologous gene expression in prokaryotes, lower eukaryotes and mammalian cells, phage genetics, immunoprecipitation/peptide mapping, posttranslational modification and secretion, are the particular fields in which prospective candidates should qualify. Successful candidates will join an active research team. They will also benefit from an excellent infrastructure and collaboration with the various research institutions in Basle, e.g. the Biozentrum, the Friedrich Miescher-Institute and the Basle Institute of Immunology. They will take part in stimulating research activities on challenging projects.

Applications with curriculum vitae, description of research background and interests and at least two references should be sent to Dr. U. Späti, CIBA-GEIGY Limited, Personnel Department, Postfach, CH-4002 Basle.

CIBA–GEIGY

(935)A

UNIVERSITY OF LIVERPOOL
SERC Daresbury Laboratory
SENIOR RESEARCH ASSISTANT
Synchrotron Radiation Studies of the Structure of Cytochrome C_4

Applications are invited for this post, which is jointly funded by MRC and SERC, with the dual purpose of promoting protein crystallographic research and supporting users of the synchrotron radiation facility. The Senior Research Assistant, working at Daresbury Laboratory, will assist with the development and running of the protein crystallography work stations and will take part in the X-ray crystallographic study of the reduced form of the bacterial protein cytochrome C_4 in association with Dr. Marjorie Harding, Liverpool University, and Dr. Lindsay Sawyer, Napier College, Edinburgh.

Candidates should have a Ph.D. degree in protein crystallography; experience with synchrotron radiation and/or computer programming will be an advantage. The post is tenable from 1 March 1984, for one year in the first instance, with the possibility of renewal for two more years.

Initial salary in the range £7,190 — £8,080 per annum (candidates should not be more than 26 years of age).

Applications, together with the names of three referees should be received not later than 31 January, 1984, by the Registrar, the University, P.O.Box 147, Liverpool. L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/197N. (940)A

THE UNIVERSITY OF MELBOURNE

RESEARCH FELLOW (Grade 1) (Temporary) in the SCHOOL OF PHYSICS

The Australian Research Grants Scheme has funded a Research Associateship for work with Professor B H J McKellar on the project "Weak Interactions".

Applicants should have a PhD in theoretical physics with a background in either particle physics or nuclear structure physics. An appointment may be made for up to two years.

Enquiries should be directed to Professor McKellar, School of Physics (03) 341 5122.

Salary up to $A21,926 per annum within the range $A20,164 to $23,100 per annum. A contribution towards the cost of travel to and relocation in Melbourne may be made to an appointee from interstate or overseas.

Further information regarding conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, Parkville, Victoria, Australia 3052, or the Association of Commonwealth Universities, (Appts), 36 Gordon Square, London WC1H 0PF.

Applications including names and addresses of at least three referees and quoting position number 640A143 should be addressed to the Staff Officer, University of Melbourne, and close on 31 March 1984. (W618)A

BREWING RESEARCH FOUNDATION

DEPUTY DIRECTOR

Applications are invited for this position, which falls vacant due to the pending retirement of Dr. J. R. Hudson.

Candidates should preferably have some experience of brewing or relevant fermentation processes but otherwise detailed requirements of academic background and experience are open. The person appointed will need to demonstrate a commitment to innovatory research, good understanding and experience of modern methods of research management, and an ability to communicate effectively and persuasively to both scientists and managers at all levels in the industry.

It is anticipated that candidates will already hold a position of responsibility in industry, the university sector or a similar research organisation.

The Brewing Research Foundation is situated in attractive countryside in Surrey yet is within easy reach of London. it was established in 1950 to carry-out co-operative research on behalf of the brewing industry. It is supported primarily by Brewers' Society on behalf of the entire British brewing industry, but has an increasing number of overseas subscribers. The Foundation enjoys an international reputation and is an acknowledged centre of excellence in brewing and fermentation research.

In the first instance, informal enquiries should be made in confidence to: Professor B. Atkinson, Director, Brewing Research Foundation, Nutfield, Surrey. Telephone: 073-782 2413. (898)A

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

SCIENTIST

Division of Marine and Freshwater Science
WELLINGTON
NEW ZEALAND

A vacancy exists in Wellington, New Zealand, at the New Zealand Oceanographic Institute (Division of Marine and Freshwater Science) for a physical oceanographer to study dynamic processes on the continental shelf. Applicants should have a PhD with 1-2 years post-doctoral (or equivalent) experience. A broad knowledge of physical oceanography is required preferably including specific expertise in coastal exchange processes.

Salary up to NZ$30,127 per annum dependent upon qualifications and experience.

DMFS is a division of the Department of Scientific and Industrial Research having a staff of 56 engaged in marine physical geological and biological research housed in a new laboratory in Wellington and 18 at the Freshwater Laboratory at Taupo. Present facilities include a 1000 tonnes research vessel, a comprehensive oceanographic library and a multi-user minicomputer linked to a network of VAX-11/780 computer with access to an IBM 3033 mainframe system.

Further information, application forms, etc., may be obtained from **the Migration Branch, New Zealand High Commission, New Zealand House, Haymarket, London SW1Y 4TQ.** Applicants should quote reference number Imm 2/335/52 (Vac 6169) and forward applications accompanied by a résumé to:

The Migration Branch,
New Zealand High Commission, New Zealand House,
Haymarket, London SW1Y 4TQ.

Closing date for applications February 17th 1984.

(924)A

Remote Sensing and Thematic Information Services

Cartographic Researcher

A vacancy exists in the Cartographic Research Group of the Remote Sensing and Thematic Information Services, Holbrook House, Swindon. The Cartographic Research Group works in co-operation with the Cartographic Production and Image Analysis Groups and also pursues independent lines of research into computer-based methods of handling, processing and display of digital data for thematic mapping. The research is currently centred on data structure design, development of spatial data bases and associated geographic information systems, integration of cartographic and remotely sensed data and colour raster graphics.

Applicants should have a good degree and experience in digital techniques for the display and analysis of geographic data. Programming skills and a knowledge of multivariate statistics would be a definite advantage.

The successful candidate will join at Scientific Officer, or exceptionally, at Higher Scientific Officer level depending on qualifications and experience. Salary scales are, presently, £5,682 to £7,765 for a SO and £7,149 to £9,561 for a HSO depending on age, experience and qualifications.

The NERC is not a Government Department but conditions of service are similar to those of the Civil Service. Applications forms, to be returned by 18 January 1984, are available from Mr. C. I. Brohier, NERC Scientific Services, Holbrook House, Station Road, Swindon, Wilts. SN1 1DE. Tel: 0793 40101 ext 523. Please quote reference: M/P 64.

Further information can be obtained from Dr. M. J. Jackson, Holbrook House, Swindon. (Tel: 0793 40101) ext 495.

NATURAL ENVIRONMENT RESEARCH COUNCIL

(909)A

SWISS TROPICAL INSTITUTE
Field Laboratory Ifakara, Tanzania
BIOLOGIST/ EPIDEMIOLOGISTS

wanted as the head of the Swiss Tropical Institute Field Laboratory at Ifakara, Tanzania.

Candidates should be experienced medical parasitologists, with a thorough background in medical laboratory techniques. They ought to be capable to direct scientific field research, to head a team of co-workers and to take care of all administrative and technical requirements related to the Field Laboratory. They ought to be fluent in English and willing to acquire a good command of Kiswahili.

Scientists, preferably of age 30-40 years, interested in a 2-4 years' contract, should apply to the Director Swiss Tropical Institute, Socinstrasse 57, CH-4051 Basel.

Conditions are negotiable, dependent on the applicant's experience. (W629)A

POSTDOCTORAL POSITION – MOLECULAR CELL BIOLOGY

Available immediately. Work will include characterization of cyto-skeletal high-molecular weight proteins, isolation of m-RNA and c-DNA cloning. Candidates should have strong background in molecular biology preferably in recombinant DNA technology. Send application to: Dr. Gerhard Wiche, Institute of Biochemistry, University of Vienna, Währinger-strasse 17, 1090 Vienna, Austria.

(W641)A

CALIFORNIA INSTITUTE OF TECHNOLOGY
DIVISION OF PHYSICS
ASSISTANT PROFESSORS
ASSOCIATE PROFESSORS
PROFESSORS

Pending budgetary approval, the Division of Physics, Mathematics, and Astronomy of the California Institute of Technology expects during the next two years to make several appointments at professorial ranks. Preferred areas of theoretical, experimental, and observational research include astronomy and astrophysics, condensed matter physics, mathematical physics, nuclear physics, particle physics, and statistical physics.

Applicants should write, as soon as possible but no later than 1 February 1984, to the Chairman of the Division of Physics, Mathematics and Astronomy, 103-33, Caltech, Pasadena, CA 91125, giving curriculum vitae, publication list, and a list of references. Caltech is an Equal Opportunity Affirmative Action Employer. (NW145)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
DEPARTMENT OF CHEMICAL PATHOLOGY
SENIOR RESEARCH OFFICER (POSTDOCTORAL IN MOLECULAR BIOLOGY

Applications are invited for positio of Senior Research Officer (Pos doctoral) to work on a molecula analysis of gene expression in mous brain. The project is funded for years by the Medical Researc Council and is due to start in Marc 1984. Initial salary including Londo Allowance will be in the range £8,37 to £9,716 according to experience.

Informal enquiries may be made Dr S Legon (tel: 01-743 2030 ext 40 and further particulars and appl cation forms are available from th Personnel Office, Royal Pos graduate Medical School, 1 Ducane Road, London W12 0H quoting reference number 4/SL.

Closing date: 26 January 1984.

(911)A

UNIVERSITY OF ALABAM IN BIRMINGHAM
RESEARCH ASSOCIA

Position available immediately f post-doctoral scientist to participa in studies involving molecul cloning and expression of viral gen Should have previous experience wi recombinant DNA technique $16,000 to $27,000 depending experience.

Send curriculum vitae and thr letters of reference to: Dr R Compans, Department of Mic biology, University of Alabama Birmingham, Birmingham, 35294, USA An Affirmative Actio Equal Opportunity Employer.

(NW169)A

UNIVERSITY OF SOUTH CAROLINA/GEOLOGY
DEPARTMENT OF GEOLOGY
invites applications for
TWO ANTICIPATED TENURE-TRACK POSITIO

in two of the following areas: 1) Geophysics; 2) Igneous Petrolo Structure; 3) Coastal Processes; 4) Organic Sediments. It is ant pated that the appointments will b the assistant professor level, applications from more sen persons will also be given strong c siderations.

A PhD degree is required. Start date will be August, 1984, with application deadline of 1 Ma 1984. Applicants should s curriculum vitae, statement research interests, pertinent repri and the name of three references Dr Bjorn Kjerfve, Department Geology, University of So Carolina, Columbia, SC 29 (Phone 803-777 4529).

The University of South Caro is an Equal Opportunity Empl which encourages applicants fr qualified minority groups women. (NW148)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF BIOCHEMISTRY

POSTGRADUATE RESEARCH ASSISTANT

A three year post funded by the SERC Biotechnology Directorate is available from January 1984. The project will be to investigate the leader sequences involved in enzyme excretion in Streptomyces. The DNA encoding some selected extracellular enzymes will be cloned and sequenced. The leader sequences which enable proteins to be exported will be investigated by deletion and site directed mutagenesis.

Starting salary (Research Assistant IB scale) £7,496 (Pt 1) inc London Allowance.

Applications, inc a full cv and the names of two academic referees, are invited from graduates in Microbiology or Biochemistry to Dr John M Ward, Department of Biochemistry, University College London, Gower Street, London WC1E 6BT. (915)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF ZOOLOGY

Postdoctoral position in Neurobiology available immediately to study the physiology, morphology or pharmacology of local interneurones in the insect central nervous system. The project is expected to be funded by N.I.H. for three years. Salary from £7630 pa depending on qualifications and age.

Send C V and names of two referees to Dr M Burrows, Department of Zoology, Downing Street, Cambridge CB2 3EJ. (927)A

PLANT BREEDING INSTITUTE

Maris Lane, Trumpington
Cambridge CB2 2LQ

MOLECULAR/CELL BIOLOGIST

A Molecular/Cell Biologist is required to assist in isolating and characterising plant genes and studying the expression of these genes in prokaryotic and eukaryotic organisms. Duties will consist of maintaining stocks of strains of a variety of organisms, preparing media, isolating plasmids and bacteriophage lambda vectors, constructing recombinant DNA molecules, radioactive labelling and using immunological detection methods.

Appointment will be at Scientific Officer (salary £5,682 to £7,765 pa). Non-contributory pension scheme.

Qualifications are a degree in a relevant biological subject in which biochemistry and microbial genetics are a major feature.

Applications with curriculum vitae and the names and addresses of two referees should be sent to the Establishment Officer by 2 February 1984.

Please quote Reference CYT/166. (899)A

THE UNIVERSITY OF MINNESOTA

THE DEPARTMENT OF PHYSIOLOGY

ASSISTANT PROFESSOR PHYSIOLOGY

The University of Minnesota invites applicants for two tenure-track appointments at the Assistant Professor level beginning about July 1, 1984. Selection will be based primarily on demonstrated research excellence. Applicants must have at least one year of postdoctoral experience and be prepared to carry out independent research. The research may involve any system or tissue but preference will be given to applicants who utilize the methods of cell biology to examine physiological problems.

Areas of particular interest include: membrane transport, intracellular concentration measurements, single channel studies, quantitative biology of excitable membranes, membrane reconstitution of transport proteins, tissue culture.

The applicant will be expected to participate in the graduate and undergraduate teaching programs of the department. Send curriculum vitae, including undergraduate and graduate transcripts, a summary of planned research and the names and telephone numbers of three references to: Search Committee, Department of Physiology, 6-255 Millard Hall, 435 Delaware Street SE, University of Minnesota, Minneapolis, Minnesota 55455.

The University of Minnesota is an equal opportunity educator and employer and specifically invites and encourages applications from women and minorities. (NW149)A

UNIVERSITY OF WASHINGTON

DEPARTMENT OF MICROBIOLOGY AND IMMUNOLOGY AND THE REGIONAL PRIMATE RESEARCH CENTER

IMMUNOLOGIST

Candidates sought for junior faculty position in basic immunology or immunogenetics. The appointee's research activities would include, but not be limited to, identification and exploitation of research opportunities provided by a large, long-established colony of nonhuman primates. A research program of interrelated human and nonhuman primate genetics would be particularly welcome. Previous primate experience not required. The primary selection criteria will be evidence of scientific excellence and promise of independent research of highest academic standard.

Send letter of application, curriculum vitae, and three personal references to: Douglas M Bowden, MD, Chairman, Search Committee, Regional Primate Research Center SJ-50, University of Washington, Seattle, WA98195, Telephone: (206) 543 1430. Affirmative Action/Equal Opportunity Employer. (NW165)A

NORTH ATLANTIC TREATY ORGANIZATION

SACLANT ASW RESEARCH CENTRE

A research organization specializing in underwater acoustics, oceanography, operational research, and system studies is seeking a

SCIENTIFIC EDITOR

to give substantial assistance to the Head of the Scientific and Technical Information Department in aiding research staff and management to prepare written and oral reports of the organization's research work. Duties will include working with authors on the contents of reports and presentations and with technical typists, draughtsmen, photographers and printers on the various aspects of publication. Assistance in the administration of the Department will also be required.

Prospective candidates should possess a scientific or engineering degree or equivalent, preferably followed by research experience and at least 3 years recent experience in editing and/or writing scientific/technical publications. A knowledge of in-house publication techniques would be an advantage. Candidates must be of English mother tongue, with writing skills and ability to edit scientific papers written in English by authors having other mother tongues. A working knowledge of French and Italian would be advantageous.

The successful candidate will initially be offered a fixed appointment of 3 years following which, if mutually agreed, an indefinite duration contract will be offered. Salary on appointment will be in the range of 30 000 000 to 37 000 000 Italian lire per year, depending on family status. All emoluments are tax free.

Applications including curriculum vitae should be forwarded no later than 1 March 1984, addressed to the Civilian Personnel Officer, SACLANT ASW Research Centre, Viale San Bartolomeo 400, 19026 La Spezia, Italy. (W631)A

Technische Universität Berlin

INSTITUT OF BIOCHEMISTRY AND MOLECULAR BIOLOGY

3 POSTDOCTORAL POSITIONS BIOCHEMISTRY, MICROBIOLOGY, BIOTECHNOLOGY

To conduct research in the field of bacterial beta-lactam biosynthesis. Positions are available immediately for two years.

The starting salary will depend on age and experience but will be on the Range BAT scale.

Applicants should have PhD in biochemistry, microbiology or biotechnology. Applications, including curriculum vitae and three letters of recommendation, should be sent to: Technische Universität Berlin, Der Präsident, II A 13, Straße des 17. Juni 135, 1000 Berlin 12 (West-Germany). Telephone: (030) 314-4205.

(W616)A

ZWO

The Netherlands organization for the advancement of pure research (Z.W.O.) and the Science and Engineering Research Council (SERC) are collaborating to enhance the experimental facilities for EXAFS and small angle scattering at the Synchrotron Radiation Source (SRS) at the Daresbury Laboratory.

The SRS is the world's first high energy electron storage ring specifically designed to provide synchrotron radiation to a broad range of experiments in the x-ray, vuv and other regions of the electromagnetic spectrum.

Z.W.O. wishes to appoint a

x-ray spectroscopist

to help develop and operate the EXAFS station on the Anglo-Dutch beamline.

The successful applicant will join the in-house team of scientists at Daresbury (of which one member is already a full time employee of Z.W.O.) and will be expected to be actively engaged in the commissioning of the new EXAFS station and its scientific programme. Experience in synchrotron radiation or in a relevant field of x-ray spectroscopy with a practical knowledge of instrumentation and computing would be desirable. Opportunities exist to engage in research with both dutch and british collaboration in fields range from structural studies of catalysts to proteins.

The appointment is initially for a fixed term of 3 years at a starting salary (depending on qualifications and experience) of Dfl. 3.765,— monthly (including foreign service allowance) or, in the case of a british person of £ 837,— monthly without a foreign service allowance.

Applications forms and further particulars are available from professor R. Prins, technical university of Eindhoven, Netherlands (040-473078) or, dr. S. S. Hasnain, Daresbury Laboratory, Warrington WA 4 4 AD, U.K. (0925-65000, extn. 273).

Further information about the post is available from these persons.

Completed applications should be returned by 10 January 1984 to Z.W.O. (reference 68-1), P.O. Box 93138, 2509 AC The Hague, the Netherlands.

(W623)A

Allelix

MICROBIOLOGISTS

Allelix Inc., Canada's first major biotechnology company, is seeking microbiologists to work in fermentation microbiology and plant cell culture. The research will involve fermentation of a variety of microorganisms and plant cells, isolation of mutant strains of bacteria and isolation and identification of microbial and plant cell products. Applicants should have a PhD in microbiology or plant biology and research experience in industry, a university or a research institute.

The founders of Allelix have provided strong financial backing. Research is conducted in a modern, well-equipped laboratory near Toronto, a dynamic, multi-cultural city offering a full scope of activities and interests. Four major universities are easily accessible. Salaries and benefits are at fully competitive levels.

Interested candidates are invited to send complete résumés, including three references and quoting file number 0060 to:

Dr. D. C. Burke
Allelix Inc.
6850 Goreway Drive
Mississauga, Ontario
L4V 1P1 Canada.

(NW168)A

FACULTY POSITIONS IN ASTRONOMY AND ASTROPHYSICS

COLUMBIA UNIVERSITY

The Department of Astronomy and the Astrophysics Laboratory of the Department of Physics at Columbia University plan to make at least four (4) appointments at the assistant professor level, to begin in the summer or fall of 1984. One position in the Astrophysics Lab is for an experimental physicist or an astronomer with an extensive background in instrumentation development to work initially, on funded and planned X-ray and gamma-ray astronomy experiments which will fly on the Space Shuttle and future satellite missions. A second position in Physics is available for anyone with a background and/or interest in high energy astrophysics; research activities currently include analysis of *Einstein* and EXOSAT data, complementary radio and optical observing programs, as well as interpretive and statistical investigations. The Department of Astronomy also has two assistant professor positions open. Candidates with interests in any field of observational and theoretical astronomy are encouraged to apply. Current work in the Department of Astronomy includes observational and millimeter radio astronomy and theoretical investigations in star formation, galactic structure, and the atmosphere and winds of early-type stars. At least one tenure appointment is expected within the next five years, and successful applicants can expect to be considered for this position in due course.

Applicants should include a résumé and letter of interest together with a list of three persons from whom recommendations can be obtained upon request; the letter should state their preference (if any) among the above positions. Columbia University is an equal opportunity employer with a strong affirmative action program, and encourages applications from women and members of minority groups. Mail applications to either Prof. R. Novick, Director, Columbia Astrophysics Laboratory or Prof. L. Lucy, chairman, Search Committee, Department of Astronomy, 538 West 120th Street, New York, New York, 10027.

(NW175)A

MEDICAL RESEARCH COUNCIL

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Division of Developmental Biology

Applications are invited from postdoctoral scientists for a non tenured position. The vacancy is for a developmental biologist to work alongside Dr Jonathan Cooke to study the biochemical basis of pattern formation during early amphibian development. The successful candidate will be familiar with theoretical models of development and with modern biochemical techniques.

The appointment will be for five years and the salary will be at an appropriate point on the scales for University non-clinical academic staff, plus £1,186 London allowance and superannuation provision.

Applications, giving a full curriculum vitae, research experience and the names of two professional references, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA, before 27th January 1984 quoting ref: DB/ 1/ S. (907)A

The European Molecular Biology Laboratory, a research institute situated in Heidelberg, West Germany, invites applications from nationals of the member states (Austria, Denmark, France, Federal Republic of Germany, Israel, Italy, The Netherlands, Sweden, Switzerland and The United Kingdom) for the following vacancy

TECHNICAL ASSISTANT

The research of the group is concerned with the determination of three-dimensional structure of protein by means of X-ray diffraction. Applicants will be expected to use the standard laboratory techniques of protein purification. Some knowledge of microbiological or crystallographic techniques would be an advantage. An above average salary will be offered to the successful candidate. Certain allowances are payable in addition, depending on personal circumstances, An initial contract of 3 years' duration which can be renewed, will be offered.

Please write briefly for an application form quoting reference No 83/42 to: EMBL, Personnel Section, Postfach 10.2209, D-6900 Heidelberg. (W615)A

UNIVERSITY OF SALFORD

GEORGE RAMAGE CHAIR IN ORGANIC CHEMISTRY

Applications are invited for the George Ramage Chair in Organic Chemistry. The Department of Chemistry and Applied Chemistry has a very active research programme including that in Organic Chemistry. Funds are also available to appoint a Lecturer in the Organic Section.
Salary within the Professorial range and not less than £17,275 p.a.
Letters of application should be received by the Registrar, University of Salford, Salford M5 4WT from whom further particulars may be obtained by 3rd February 1984. Please quote reference no. CH/287/N. (906)A

UNIVERSITY OF BIRMINGHAM
FACULTY OF SCIENCE AND ENGINEERING
CHAIR OF GEOPHYSICS AND HEADSHIP OF DEPARTMENT OF GEOLOGICAL SCIENCES

Applications are invited for the Chair of Geophysics and Headship of the Department of Geological Sciences, which will become vacant from 1 October 1984 on the retirement of Professor D H Griffiths. The office of the Headship need not necessarily be linked with appointment to the Chair.

Salary in the Professorial range, with superannuation.

Further particulars available from the Registrar, University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (12 copies, 1 from overseas applicants) should be sent by 13 February 1984. (900)A

UNIVERSITY OF CINCINNATI MEDICAL CENTER
PEPTIDE CHEMIST

Selected sequences and analogues of Gastrointestinal and neuronal polypeptides will be synthesized using solid phase methodology. The products will be used for structure function studies and for raising antibodies in collaboration with a research team of biochemists and physiologists. Sequences of apolipoproteins and haemolytic toxins are also being synthesized. The position is for three years beginning as soon as possible after April 1, 1974.

Applicants should send a curriculum vitae and names of referees to Dr R F Murphy, Department of Surgery, University of Cincinnati Medical Center, 231 Bethesda Avenue, Cincinnati, Ohio, 45267. (NW161)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS
POST-DOCTORAL RESEARCH ASSOCIATE

Applications are invited for the post of Research Associate to work on a project, funded by The Wellcome Trust, on the properties and regulation of dopamine D_2 receptor-effector mechanisms in the central nervous system. The project includes analysis of intra- and extracellular cyclic nucleotides, inositol phospholipid hydrolysis and receptor labelling techniques.

The successful candidate should possess a PhD (or shortly expect to receive one) and have some experience in biochemical pharmacology/neurochemistry. The appointment will be for three years on the 1A Scale for Research Staff (starting salary £7,630 pa).

Applications (with curriculum vitae and the names of two referees) to and further details from Dr S R Nahorski, Department of Pharmacology and Therapeutics, Medical Sciences Building, University of Leicester, University Road, Leicester LE1 7RH, UK (0533) 551234 ext 361.

Closing date for applications 15th February 1984. (892)A

POSTDOCTORAL POSITION IN IMMUNOLOGY

The candidate should be interested in the molecular mechanisms of antigen processing and presentation. Background in membrane and/or protein chemistry desirable.

Interested individuals should send curriculum vitae and the names and telephone numbers of three references to: Dr Howard Grey, Division of Basic Immunology, Department of Medicine, National Jewish Hospital & Research Center, 3800 E Colfax Avenue, Denver, CO 80206. (NW156)A

UNIVERSITY OF OXFORD
DEPARTMENT OF CLINICAL PHARMACOLOGY
Radcliffe Infirmary
Oxford OX2 6HE
Re-advertisement
POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for this position funded by The Wellcome Trust, to study the effects of drugs on 5-hydroxy-tryptamine-mediated phosphatidylinositol breakdown in rat brain tissue and human platelets.

The applicant should have a higher degree in biochemistry or pharmacology and some experience in the area of phospholipid metabolism. The appointment is for 3 years; starting salary will be in the range £7,190 — £8,530.

Applications, together with a curriculum vitae, list of publications and the names of two referees, should be sent to Professor D G Grahame-Smith at the above address. Closing date for applications: 20th January 1984. (917)A

London School of Hygiene and Tropical Medicine
(University of London)

MSc in Human Nutrition

A comprehensive, academic training in the subject of human nutrition is provided through a full-time, one calender year, course. During the first two terms a core course in nutrition, metabolism, physiology, statistics and epidemiology, health-care and economics is taken by all students. The third term consists of options including nutrition in community health and clinical nutrition, nutritional metabolism and socio-economic aspects of nutrition. A research project is completed during July-September.

The curriculum is designed to provide orientation in nutrition for graduates with a range of academic backgrounds (medicine, science or social science) in order to meet the nutritional problems that professionals will encounter in developing and developed countries. The next course commences on October 1st, 1984.

Further details may be obtained from The Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT. (916)A

RESEARCH Associate to carry out research involving cell culture and the isolation of centromeres from metaphase chromosomes, analyzing proteins and DNA from these fractions and preparing monoclonal antibodies. Cloning of DNA is also required. Must have PhD in Cell Biology, Biochemistry or related area with 2 yrs postdoctoral experience. Must also have English speaking and writing skills. $15,000/year. 40 hrs/wk. Apply at the Texas Employment Commission, Houston, Texas, or send résumé to Texas Employment Commission, TEC Building, Austin, TX 78778, JO No 3223086. Ad Paid by an Equal Employment Opportunity Employer. (NW176)A

UNIVERSITY OF FLORIDA
DEPARTMENT OF ASTRONOMY
FACULTY POSITION IN ASTRONOMY

invites applications for a tenure-track position as assistant or associate professor, beginning with the fall term, 1984. The successful candidate must have an outstanding record of research, and if applicable, of outside support.

The salary will be commensurate with qualifications, at a highly competitive level. Although any research speciality will be considered, preference may be given to VLBI or other radio astronomy research, solar system astronomy, or space astronomy.

Send curriculum vitae and names and addresses of at least 3 references to T D Carr, Search Committee Chairman, Department of Astronomy, University of Florida, Gainesville FL 32611, by February 15, 1984. The University of Florida is an equal opportunity/affirmative action employer. (NW144)A

SILVICULTURE — ASSOCIATE Professor or Professor (tenure track, 12-month). Provide instruction (60%) and research (40%) in silviculture. Teach undergraduate and graduate silviculture course. Conduct research related to extensively managed forest. Opportunity for team research on cooperative programs with industry and federal and state agencies. Earned PhD in silviculture or closely related discipline with one degree in forestry required. Demonstrated teaching and research ability required. Send application, résumé, transcripts and three letters of recommendation to: Arnett C Mace, Jr, Director, School of Forest Resources and Conservation, University of Florida, Gainesville, Florida 32611. Closing date is February 2, 1984. (NW146)A

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANT IN MOLECULAR GENETICS

in a research group examining the distribution and interrelationships of Type II restriction-modification systems. Preference will be given to applicants with a sound training in the techniques of either protein chemistry, or bacterial culture, or recombinant DNA work.

The appointment is for three years from 1st March 1984. The starting date may be held open for an excellent candidate. The salary will be in the Range 1A (commencing between £7,190 and £8,530 pa depending on age).

Applications including cv and the names of two academic referees should be made as soon as possible to Dr N L Brown, Department of Biochemistry, University of Bristol, University Walk, Bristol BS8 1TD UK. (893)A

Royal Army Medical College
Millbank, London

Microbiologist

...to manage a small animal unit. Duties involve providing a routine diagnostic service including viral isolation and mycobacterial isolation and identifiction. The successful candidate will also train Army laboratory technicians and participate in the development and assessment of new methods.

Candidates should have a degree/HND/HNC/AIMLS or equivalent in microbiology and at least one year's experience of medical microbiology laboratory work. Concern for the welfare of experimental animals is desirable.

Appointment as Scientific Officer £6930-£9015 (including £1250 Inner London Weighting) with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 27 January 1984) write to Ministry of Defence, CM(S)1b3, Room 310, Savoy Hill House, Savoy Hill, Strand, London WC2R 0BX.

Please quote ref: SA/6/ET.

(897)A **Scientific Civil Service**

UNIVERSITY OF ARIZONA

DEPARTMENT HEAD

The University of Arizona invites applications for the post of Head of the Department of Physics. A distinguished physicist and outstanding administrator is sought to lead this research and teaching department through an anticipated period of intellectual growth over the next decade. Presently the Physics Department consists of around forty faculty members, and it anticipates regular and frequent opportunities to recruit new members during the next several years. A substantial expansion of the physical facilities is currently under way. The University of Arizona is situated in a vital and expanding economic and social environment. The past decade has seen major growth in scientific activities at the University which is presently ranked twenty-first among the nation's universities in the amount of external support received. The Department of Physics is expected to participate in this continuing growth in the years ahead.

Applications, nominations and inquiries should be directed to Professor Henry A. Hill, Chairman of the Search Committee, Department of Physics, University of Arizona, Tucson, Arizona 85721. Informal inquiries are welcome and may be directed to Henry Hill (602) 621-6782. Applications should be accompanied by a complete vita and bibliography, as well as the names of at least three references who can assess the applicant's scientific accomplishments and leadership skills. Letters of recommendation will not be sought until authorized; The University of Arizona is an Equal Opportunity/Affirmative Action Employer. (NW177)A

THE UNIVERSITY OF MUNICH

DEPARTMENT OF NEUROBIOLOGY

POSTDOCTORAL POSITION

Applications are invited for a postdoctoral scientist to work on the localization of transmitters in the extrapyramidal system using mainly immunocytochemical techniques. Experience in EM and/or behavioural methods would be an advantage.

Position funded by the German Research Association (BAT II a, appr. DM 60 000 p.a. before tax) is available immediately for 1 year with possible extension for further two years.

Send complete curriculum vitae and 3 letters of reference to: PD Dr C. Nitsch, Anatomische Anstalt, Pettenkoferstr. 11, D-8000 München 2, West-Germany. (W636)A

ALBERT EINSTEIN COLLEGE

THE DEPARTMENT OF NEUROSCIENCE

seeks several investigators at the

ASSISTANT PROFESSOR

level with interests in cellular and molecular neurobiology. These individuals will be expected to carry out their own research programs, but members of the department have often engaged in collaborative work involving the differing expertise of the participants.

Applicants should contact Michael V L Bennett, Chairman of the Dept of Neuroscience, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, NY 10461. An Equal Opportunity Employer. (NW158)A

SOUTHAMPTON PHLS SENIOR MLSO

required to specialise in the assessment of new techniques relevant to diagnostic microbiology. Applications are invited from MLSOs, Scientific Officers or graduates in biochemistry, cell biology, immunology or microbiology to work on the introduction and assessment of molecular techniques relevant to clinical epidemiology and diagnostic microbiology.

The successful applicant would be expected to work on this project for up to three years, during which time appropriate training and expertise will be offered by arrangement with the collaborators in the Southampton PHLS/North American Molecular Epidemiology programme. Experience with radioisotopes, statistics and computing would be an advantage.

Further information can be obtained from Dr A. D. Pearson, PHLS, Level B, South Block, Southampton General Hospital, Tremona Road, Southampton, Hants SO9 4XY, or tel: Southampton (0703) 776177.

(930)A

THE UNIVERSITY OF EDINBURGH

DEPARTMENT OF PHYSICS

RESEARCH FELLOW

Applications are invited for the position of post-doctoral research fellow within the Condensed Matter Group in the Physics Department. The research activities of this group lie largely in the field of phase transitions and critical phenomena, and the successful applicant will be expected to engage in theoretical work in this area, with particular emphasis on Monte Carlo studies using the Edinburgh Distributed Array Processors. Experience in the area of phase transitions and with computing would be an advantage.

The position, which is supported by the S.E.R.C., is available for a period of up to three years, and the appointment will be made on the 1A scale at a point commensurate with age and experience.

Applications, giving full details of the candidate's qualifications and research interests, should be sent to: Dr A.D. Bruce, Physics Department, James Clerk Maxwell Building, Mayfield Road, Edinburgh EH9 3JZ.

Applicants are requested to arrange for letters of support from two referees to be sent directly to the above address. Please quote reference No. 5142. (937)A

UNIVERSITY OF ADELAIDE

invites applications from both m and women for the followi position:

LECTURER in ANIMA SCIENCES (E1073) (Tenurable)

Waite Agricultural Research Institute

in the area of animal nutrition nutritional Physiology.

Applicants should currently actively engaged in studies on so aspect of nutrition or physiology ruminant farm animals, with par ular reference to the grazing anim The appointee will be required to up a research laboratory, and initi research programmes with farm a experimental laboratory animals a there are opportunities for coll oration with other members of Department in the fields of endoc ology and biochemistry. T appointee will also participate teaching in the Animal Scien course at undergraduate level Agricultural Science students will be required to supervise p graduate students.

The position is available from e 1984.

Further information on resea and teaching facilities in Department of Animal Sciences n be obtained from the Chairm Professor B P Setchell.

It is University policy to encour women to apply for considertion appointment to, in particul tenurable academic positions.

Holders of full-time tenured tenurable academic appointm have the opportunity to take le without pay on a half-time basis f specific period of up to ten y where this is necessary for the car children.

Further information about General Conditions of all appo ments may be obtained from Personnel Manager of University.

Salary per annum: Lect $A23394 × 7 — $30734.

Applications, in duplicate, quo reference number and giving personal particulars (includ citizenship, details of acade qualifications and names addresses of three referees, sh reach the Personnel Manager of University of Adelaide, GPO 498, Adelaide, South Australia (Telex: UNIVAD AA89141), later than 17 February 1984.

The University reserves the r not to make an appointment o appoint by invitation. (W634)

POSTDOCTORAL POSITION

available immediately for person with background in membrane biochemistry and cell biology. Expertise in the characterization and tissue localizsation (EM level) of membrane proteins by immunological methods highly desirable. Person will join a group working on membrane protein synthesis and turnover in lact mamary tissue. Salary $16,000 annum.

Send curriculum vitae and t references to Dr I H Mather, Animal Sciences, University Maryland, College Park, Mary 20742. Tel: No. 301-454 3733. Equal Opportunity/Affirma Action Employer. (NW162)

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF PATHOLOGY
POST DOCTORAL RESEARCH ASSISTANT

pplications are invited from suitably qualified persons for the position of Post Doctoral Research ssistant to join Professor Wildy and r Nash's group working on mmunological responses to herpes mplex virus. The successful candidate will work on the culture and haracterisation of mouse T-cell lones, some of which have already een isolated. Some previous xperience in animal cell culure nd/or immunochemistry is esirable. The project is supported by grant from the Medical Research ouncil for three years. Salary on niversity Scale up to £9875 epending on age. Age not above 30.

Applications, together with curriculum vitae and the names and ddresses of two referees should be ent to The Superintendent, Department of Pathology, Tennis Court oad, Cambridge CB2 1QP. Closing ate 31 January 1984. (926)A

NSTITUTE Of Cancer Research: Senior Technician required to work n the Institute's Human Genetics Section at the Royal Marsden Hospital, Fulham Road, SW3. The applicant would work on a project now in progress to determine the genetic origin of molar pregnancies. The study includes the use of tissue culture, cytogenetics and flow cytometry. A person with experience in tissue culture and/or cytogenetics would be preferred. For further details of the work contact Professor S D Lawler or Miss R A Fisher on 01-352 8171 ext 357. Starting salary will be in the range £7,197 pa — £8,126 pa plus London Allowance of £997 pa. Applications in duplicate with the names of two referees to the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref 301/B/41. (903)A

STANFORD UNIVERSITY
DEPARTMENT OF GENETICS
ASSISTANT PROFESSOR

Having scientific interests in areas of human genetics (for example, cytogenetics, human biochemical genetics), cellular genetics (particularly chromosome structure and function) or molecular genetics of higher eukaryotes, especially mammalian organisms. Full-time, tenure-track position that involves teaching and independent research.

Send curriculum vitae, bibliography and names of three referees to: Dr Stanley N Cohen, Chairman, Department of Genetics, Stanford University Medical Center, Stanford, CA 94305. Stanford University is an affirmative action employer and welcomes nominations of women and minority group members and applications from them. (NW151)A

ASSISTANT OR Associate Specialist. It is anticipated funds will be available from a grant from the National Science Foundation or the National Institutes of Health for two years, starting April 1, 1984, with possibility of renewals, to support a full-time individual ($19,848-$22,728/$24,972-$30,084) to study mice at molecular and organismal levels. Emphasis will be on animals from European hybrid zones. Applicant must be experienced at field collection and identification of diverse members of the house mouse complex and at maintenance of a mouse colony. Laboratory proficiency required in mitochondiral DNA purification and restriction analysis, electrophoretic surveys of proteins encoded by many loci, quantitative morphological measurements, karyotypic analysis. Candidate must have at least three years work beyond the PhD, experience in supervisory and instructional capacities, and a publication record testifying to expertise in the areas involved in the project. Knowledge of German, French, Italian desirable. Send résumé, names of three references, copies of relevant publications by 15 January 1984 to: Dr Allan C Wilson, Department of Biochemistry, University of California, Berkeley, CA 94720. UC Berkeley is an Equal Opportunity, Affirmative Action Employer. (NW153)A

THE UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF BIOCHEMISTRY
POSTGRADUATE RESEARCH ASSISTANT

Applications are invited for the above post on an MRC-funded 3 year project to investigate changes in dolichol, phosphodolichol and glycoprotein metabolism in tissues of mammals as they age. Candidates should have a good honours degree in Biochemistry or in a related subject. The possibility of registering for a higher degree would be considered.

Applications including a curriculum vitae and names of two referees should be submitted by January 21st to Professor F W Hemming, Department of Biochemistry, Queen's Medical Centre, Nottingham NG7 2UH. (0602 700111 ext 3619). (901)A

UNIVERSITY OF READING
DEPARTMENT OF AGRICULTURAL BOTANY

Applications are invited for a
LECTURESHIP

with special responsibility for Weed Science. Postgraduate training in ecological or physiological aspects of weed science desirable.

The appointment will be for a fixed period of 5 years from 1 May 1984 or as soon as possible thereafter. Salary scale £7,190 to £14,125 pa plus USS/USDPS benefits.

Further particulars and application forms (2 copies) are available from the Personnel Officer, University of Reading, Whiteknights, Reading, Berks RG6 2AH. Tel: (0734) 875123 ext 220. Please quote Ref AC 841. Closing date 31 January 1984.

(894)A

UNIVERSITY OF GLASGOW

Applications are invited for 2 new Chairs, tenable from 1st October, 1984 or such date as may be arranged.

1. **CHAIR OF MATHEMATICS** (Ref. no. *5285/M*)
The appointment will be in applicable mathematics. Preference may be given to candidates whose main research interests are in some branch of applied analysis, such as (ordinary or partial) differential equations or continum mechanics; but other fields will also be considered.
Closing date for applications: 3rd February, 1984.

2. **CHAIR OF ASTROPHYSICS** (Ref. no. *5186/M*)
Although the successful candidate will be a member of the Department of Astronomy, a major responsibility of the post will be to help guide and develop collaborative research and teaching in the Departments of Natural Philosophy and Astronomy as part of their long term plant for closer association of the two Departments.
Closing date for applications: 13th February, 1984.

Further particulars may be obtained from the Secretary of the University Court, (Room 18), University of Glasgow, Glasgow, G12 8QQ, with whom applications (2 copies), giving the names and addresses of not more than three referees, should be lodged.
In reply please quote appropriate Ref. No. (943)A

UNIVERSITÄT FREIBURG

Am Institut für Biologie III der Albert-Ludwigs-Universität Freiburg i. Br. ist die Stelle eines

PROFESSORS

der Besoldungsgruppe C3 wieder zu besetzen.

Vom Stelleninhaber wird erwartet, daß er sich innerhalb der am Institut vertretenen Gebiete (Genetik, Molekularbiologie einschließlich Gentechnologie, Genexpression bei Eukaryoten, Genetik und Biophysik neuraler Systeme) angemessen an Forschung und Lehre beteiligt. Bei gleicher Qualifikation werden Bewerber bevorzugt, die eine neurobiologische Forschungrichtung mit molekularem und/oder genetischen Ansatz bearbeiten und die in der Lage sind, auch Lehraufgaben im Rahmen des Biophysik-studiengangs zu übernehmen. Eingliederung in einen der in Freiburg bestehenden Sonderforschungsbereiche ist erwünscht.

Bewerbungen mit Publikationsliste, wissenchaftlichem Werdegang und Skizzierung zukünftiger Forschungspläne sind zu richten an den: Dekan der Fakultät für Biologie, der Universität Freiburg i.Br., Schänzlestraße 1, 78 Freiburg i.Br.
Letzter Bewerbungstermin 15. März 1984 (W639)A

UNIVERSITY OF MUNICH
DEPARTMENT OF PHYSIOLOGY
NEUROPHYSIOLOGIST

3 year postdoctoral position available immediately to study neuronal properties in mammalian brain slices under normal and epileptic conditions. In vivo experience with microelectrodes is advantageous. Knowledge of German is not essential. Applications with curriculum vitae and names of 2 referees to: Dr. M. Galvan, Physiologisches Institut, Pettenkoferstr. 12. 8000 Munich 2, W. Germany. Tel: 0049-89-5996250. (W638)A

MEDICAL RESEARCH COUNCIL
Toxicology Unit

TECHNICIAN

Required to work in Laboratory concerned with metabolism of both drugs and natural compounds. The work involves chemical, biochemical and physiological methods.

Qualifications: Degree, HNC or equivalent. Salary according to age, qualifications and experience within the range £5,491 — £7,747 plus London Weighting.

Apply in writing, with curriculum vitae and the names of two referees to: Dr. J. A. Hoskins, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

MRC
Medical Research Council

(936)A

WORLD RESOURCES REPORT EDITOR-IN-CHIEF

The World Resources Institute and the International Institute for Environment and Development seek applications for an editor-in-chief for a new annual publication, the *World Resources Report*, which will be headquartered in Washington, DC. The *Report* will provide timely, objective information on world resource, environmental and population issues for an international audience. It will contain information on resource conditions, trends, and policy developments and will present statistical indicators by country and region.

The editor-in-chief must have strong writing and editing skills, with the ability to synthesize and organize a large body of information, much of it technical, and to communicate that information effectively to a wide and diverse audience, much of it non-technical. Knowledge of the scientific and policy dimensions of international resource, environmental and population issues is essential. The editor-in-chief must also show competence to manage a small staff, operate within a defined budget, effectively use editorial boards and advisors, produce the *Report* on schedule, and promote its international distribution and sale.

Candidates should send complete résumé, publication credits and the names of references to: World Resources Institute, 1735 New York Avenue, NW, Washington, DC 20006. (NW179)A

UNIVERSITY OF LONDON INSTITUTE OF PSYCHIATRY

DEPARTMENT OF NEUROLOGY

RESEARCH PSYCHOLOGIST

Applications are invited for the Post of Research Psychologist for the investigation of the treatment of spasmodic torticollis with electromyographic biofeedback. This study, which is for three years, is funded by the MRC. Clinical training is necessary.

Salary will be on the University Scale 1B for research staff (£6,310 — £8,530 pa plus £1,186 pa London Allowance).

For an application form send stamped addressed envelope to the Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF quoting ref CDM/N. Closing date for applications — 31 January 1984. (912)A

EPIDEMIOLOGIST

Seek individual with recent PhD, MD or equivalent for appointment as Assistant Professor of Epidemiology to begin Fall Semester 1984. This is tenure-track state-funded position. Recruitment is directed towards epidemiologists with interests that augment and extend research concerns of present faculty. Research interests of current faculty now include arthropod-borne virus diseases, environmental carcinogensis, psychosocial factors and heart disease, occupational diseases, and genetic epidemiology.

Submit curriculum vitae, transcripts, publications, names and addresses of 3 reference persons and a brief statement describing research teaching interests to: professor W C Reeves, School of Public Health, University of California Berkeley, California 94720. Deadline for application is March 15, 1984. The University is an Equal Opportunity Affirmative Action employer. (NW170)A

POSTDOCTORAL POSITION IN IMMUNOLOGY

Two funded postdoctoral positions are available immediately to study the structure and function of the Ia antigens. Specific projects involve establishing the antigenic fine structure of the Ia antigens using monoclonal antibodies, identifying specific interactions of Ia antigens with components of cytoskeleton and plasma membrane, and examining the details of potential interactions between foreign antigen, Ia antigen and T cell receptor during antigen presentation. Salaries to be consistent with NIH guidelines.

Prospective candidates should send curriculum vitae, three references and a summary of research interests to: Dr John H Freed, Division of Basic Immunology, Department of Medicine, National Jewish Hospital & Research Center, 3800 E Colfax Avenue, Denver, CO 80206. (NW157)A

KING ABDULAZIZ UNIVERSITY DEPARTMENT OF BIOLOGY

KING ABDUL AZIZ UNIVERSITY at JEDDAH, SAUDI ARABIA invite PhD holders to apply for vacant posts in Biology Department, Faculty of Science in the following fields:

1 — Molecular Biology.
2 — Population Biology.
3 — Microbial Physiology.
4 — Vertebrate Taxonomy.

Priority will be given to people who are able to teach in Arabic language.

Application should be forwarded to: HEAD, BIOLOGY DEPARTMENT, FACULTY OF SCIENCE, K.A.U. PO BOX 9028 JEDDAH, SAUDI ARABIA. (W630)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF CHILD HEALTH

RESEARCH ASSISTANT

Required for ongoing study, currently funded for further two years, into the process whereby antigen penetrates the pulmonary epithelium and produces immediate hypersensitivity reactions. Ultrastructural autoradiographic and immunohistological techniques are involved.

Salary range 1B (£6,310 — £8,530) and superannuation.

Applications, including a curriculum vitae and the names of two referees, to:
Dr F. Carswell, Reader in Child Health, Department of Child Health, Royal Hospital for Sick Children, St Michael's Hill, Bristol BS2 8BJ. (922)A

MOLECULAR AND Cellular Biologist. A tenure-track position for an individual with postdoctoral experience in molecular and cellular biology. Must have a strong interest in teaching and research at the undergraduate and early postgraduate levels. Responsibilities include teaching molecular and cellular biology, and modern molecular biology technologies to support our programs. The candidate will be expected to have an active, fundable research program. Appointment date: September 1, 1984. Send curriculum vitae, reprints, statement of research goals and three letters of recommendation to: Search Committee, Department of Biological Sciences, Box 152, SUNY Plattsburgh, NY 12901. Deadline: February 15, 1984. Incomplete applications will not be considered. An Equal Opportunity/Affirmative Action Employer. (NW150)A

THE MEDICAL SCHOOL, BRISTOL

DEPARTMENT OF ANATOMY

POSTDOCTORAL BIOCHEMIST

A biochemist with experience in polypeptide biochemistry is required to join a research team investigating the properties of the hormone relaxin. The work involves extraction, purification, and assay of the hormone and there are opportunities to pursue a research project which is appropriate to the expertise of the successful applicant. The salary will be in the range £7190 — £8975 per annum. The post which is funded by the Medical Research Council has some ten months to run. Application will be made for extension or renewal.

Applications together with a curriculum vitae and the names and addresses of two references should be sent to Professor D.G. Porter, Department of Anatomy, The Medical School, Bristol BS8 1TD. (941)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF AGRICULTURE

RESEARCH ASSOCIA

Applications are invited for temporary post of Resear Associate in the Department of Ag culture from a date as soon possible until 31st May 1985 to w on a project sponsored by Opencast Executive of the N.C The work will be to evaluate improve the agricultural potential land restored after opencast min and will involve detailed analysis the growth and development cereals and oilseed rape on b restored and undisturbed sit Candidates must have recent ag nomic research experience.

Salary will be on the Range scale (£7,190 — £11,615) accord to age, qualifications and experie with an initial salary not exceed £8,530 per annum.

Further particulars may obtained from the Deputy Regist (F.P.), The University, 6 Kensing Terrace, Newcastle upon Tyne N 7RU, with whom applications copies), together with the names addresses of three referees, shoul lodged not later than 20th Janu 1984. Please quote reference NS. (923)A

RESEARCH ASSOCIATE

to conduct research on the func of poly/ADP-ribose), the me nism of its synthesis in cultured and cell extracts, and its involven in DNA repair. Requirements incl PhD in Biochemistry, two y research experience, and str background in the biochemistry poly(ADP-ribose). Expertise assaying its synthesis, amou distribution and decay. Knowle of DNA repair.

Experience with gel electrophor and high pressure liquid chrom graphy; tissue culture; enz purification and kinetics; radioimmunoassay. Sal \$17,892/yr — 35 hrs/wk.

Send résumé to Mr Willis, Order No 4122, Division of Emp ment Security, Hurley Building, Center, Boston, MA. (NW167)

UNIVERSITY OF PENNSYLVANIA

DEPARTMENT OF SCHOOL OF MEDICINE

POSTDOCTORAL FELLC CELLULAR/STRUCTUR BIOLOGY

Applications are invited for a doctoral fellow, to join our rese on the structure, function, development of microtu containing organelles membrane-microtubule compl The position is supported by an Training Grant. Facilities and ex tise in all aspects of modern struct and cellular biology are avail Send curriculum vitae and names references to J. M. Mur Department of Anatomy, Scho Medicine, University of Pen vania, Philadelphia, PA 19104. (NW180)

Field Symposium on the Caledonides of the British Isles
Advanced Studies Institute sponsored by NATO

Director Dr. A. L. Harris (University of Liverpool, UK)

This field symposium will study the localities of classic interest in the Caledonides of Britain.

The field symposium will leave Cardiff, South Wales, on 19th August 1984 and will traverse the Caledonides of Wales, the English Lake District, the Southern Uplands of Scotland and the Scottish Highlands.

Localities visited will include Church Stretton, Aberystwyth, Snowdonia, Anglesey, Lake District, Moffat, Girvan, Fort William and Ullapool. Evening sessions will include discussions and lectures which will review each day's geology and place it in its context within the Caledonide-Appalachian orogen. Lecturers will include Dr. M. G. Bassett, Dr. M. P. Coward, Dr. D. J. Fettes, Professor L. M. Hall, (USA), Professor R. D. Hatcher, (USA), Dr. R. T. Haworth (Canada), Professor G. Kelling, Dr. W. S. McKerrow, Professor B. A. Sturt, (Norway).

The field symposium will end in Glasgow, Scotland, on Sunday 2nd September 1984 to enable participants to join the final symposium of I.G.C.P. Project 27 the Caledonide Orogen.

NATO regulations require those who are interested in participating in the field symposium to write to Dr. A. L. Harris enclosing a brief statement of their geological interests, a list of recent publications and the name of one referee.

Applications must reach Dr. Harris by the 31st March 1984. The number of places available on the field symposium is limited to 40. Priority will be given to applicants from outside the United Kingdom. (932)M

CONFERENCES and COURSES

Federation of European Biochemical Societies Advanced Courses in 1984

Gene Cloning and Sequencing — February 20-29, Helsinki, Finland

JAPANESE BIOTECHNOLOGY STUDY TOUR

An in-depth series of site visits, conferences and seminars with some of Japan's leading industrial scientists and executives in biotechnology.

This exclusive study tour is designed to give western scientists and executives an opportunity to become acquainted with the Japanese marketing and research capacity. The mission will be led by Christopher G. Edwards, Editor in Chief of BIO/TECHNOLOGY, and organized by the Technology Transfer Institute. Visits will be conducted throughout Japan from March 31–April 15.

For further information, contact: Technology Transfer Institute—New York, One Penn Plaza, Suite 1411, 250 W. 34th St., New York, N.Y. 10119. 212-947-2648 telex 420057TTIUI. Attention: Mr. Hashizume.

(NW174)C

FEBS International Summer School on "THE IMMUNE SYSTEM: GENES, RECEPTORS AND REGULATION"

at Ionian Village, Peloponn[illegible], Greece, September 10-20, 198[illegible].

Organisers: Drs. Papamichail, Askonas, Avrameas, Rajewsky.

Applications from PhD students and postdoctoral workers (cv, scientific background, research interests, and one recommendation letter) by 20 May 1984 to: Dr. S. Avrameas, Institut Pasteur, 28 rue du Dr. Roux, 75724, Paris Cedex 15, France. The accommodation fee will be US $200.

(921)C

MOLECULAR ENDOCRINOLOGY AND TECHNIQUES FOR HORMONE ACTION
19 to 25 February, 1984

Course will consist of lectures in methodology with comprehensive syllabus covering receptors, gene transcription, mRNA and protein synthesis, recombinant DNA, protein hormones, and cyclic nucleotides.

Co-directors: W. T. Schrader and B. W. O'Malley. Fee: $295/$195 (fellows).

For further information contact: Claudia Payne, Department of Cell Biology, Baylor College of Medicine, Houston, Texas 77030. Telephone: 713-799 6200. Deadline 6 January 1984.

(NW115)C

WORKSHOP

EMBO WORKSHOP
An EMBO International Workshop on the MOLECULAR AND DEVELOPMENTAL BIOLOGY OF DROSOPHILA

will be held at Kolymbari Crete (Greece) June 24-30, 1984. The workshop will be co-sponsored by the University of Crete and the Molecular Biology and Biotechnology Institute of the Research Center of Crete. Approximately 70 participants will be selected by the organizing committee from applicants. Applications should include a short summary of research interests and should be sent no later than January 20, 1984 to: Dr. S. Artavanis-Tsakonas, Crete Workshop, Yale University, Department of Biology, PO Box 6666, New Haven, Connecticut 06511-8112, USA.

A registration fee of $150 will be remitted upon acceptance. Local expenses in Crete will be covered by the organizers. Participants are expected to finance their travel to Crete. A small number of grants in aid for partial travel support may become available.

The organizing committee: S. Artavanis-Tsakonas (Yale University); M. Ashburner (Cambridge University); A. Carpenter (University of California); M. Gans (CNRS, Gif sur Yvette); A. Garcia-Bellido (Universidad Autonoma, Madrid); W. Gehring (University of Basel); W. Gelbart (Harvard University); D. Hogness (Stanford University); D. Ish-Horowicz (Imperial Cancer Research Fund); F. Kafatos (Crete University); D. Kankel (Yale University); J. Modolell (Universidad Autonoma, Madrid); C. Nusslein (Friedrich Miescher Institute, Tubingen); M. Pardue (Massachusetts Institute of Technology); G. Rubin (University of California). (NW114)V

ASSOCIATESHIPS

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF ORGANIC CHEMISTRY

POST DOCTORAL RESEARCH ASSOCIATESHIPS

Applications are invited from suitably qualified candidates for 2 post doctoral Research Associate posts. The first post is tenable for 3 years and is concerned with the synthesis of biologically active compounds. The second post is tenable for 2 years and is concerned with the study of the mechanism of action of vitamin B12.

Appointments will be made on the Range 1A salary scale £7,190 — £11,615 according to age, qualifications and experience with an initial salary not exceeding £7,630 per annum.

Further information may be obtained from Professor B T Golding, Department of Organic Chemistry, The University, Newcastle upon Tyne NE1 7RU (0632 328511 extension 2959) with whom applications, with the names of 3 referees should be lodged not later than 31st January 1984.

(902)O

STUDENTSHIPS

AFRC FOOD RESEARCH INSTITUTE

COLMAN'S STUDENTSHIP

Applications are invited from graduates with 1st or upper 2nd Class Honours in Microbiology, Biochemistry or related subjects for a 3-year research studentship, funded by Colman's of Norwich, to study the mechanism of inhibitionof yeasts and other acid-resistant microorganisms and by organic acids and other preservatives.

The studentship will be based in Norwich at the Food Research Institute and the work will be submitted for a PhD at the University of East Anglia. Conditions and the remuneration will be similar to those of SERC Case Awards.

Further details and application forms are available from the Secretary, AFRC Food Research Institute, Colney Lane, Norwich NR4 7UA. Closing date: 19 January 1984. (908)F

A STUDENTSHIP leading to a MSc or PhD in biological psychiatry awarded by the Department of Psychiatry, University of Saskatchewan, in a multidisciplinary area of biological psychiatry (neurochemistry, neuropharmacology, enzymology, behaviour) is available. Applications are invited from graduates with a first or upper second class honours degree or equivalent qualifications in a suitable biological subject. Interested persons should write as soon as possible to Dr A V Juorio, Psychiatric Research Division, Cancer and Medical Research Building, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N OW0, sending a curriculum vitae and the names and addresses of three referees. Non-Canadian applicants are advised to write before February 28th, 1984 and Canadian nationals or landed immigrants before July 31st, 1984. (NW143)F

THE UNIVERSITY OF SHEFFIELD

(Re-advertisement)

DEPARTMENT OF MEDICAL MICROBIOLOGY

RESEARCH STUDENTSHIP — TUMOUR IMMUNOLOGY

Applications are invited from graduates and final year students for this studentship tenable with immediate effect for 2½ years. The Studentship was previously advertised in June 1983. Applicants should have or anticipate obtaining a good degree in a branch of the biological sciences which preferably included Immunology. The research topic is the effect of tumours on macrophage function. The depression of normal macrophage function by tumour cells will be investigated in terms of induction of the immune response. Applications including c.v. and the names of 2 referees to: Dr. A. Clark, Department of Medical Microbiology, The Medical School, Beech Hill Road, Sheffield S10 2RX (Tel: (0742) 26484, Ext. 2027/2958) from whom further information may be obtained. Quote ref: R24/G.

(933)F

UNIVERSITY OF CAMBRIDGE RESEARCH STUDENTSHIPS

St Edmund's House, a graduate college of Cambridge, offers one or more Research Studentships of £375 to those commencing the PhD. Further details from The Senior Tutor, St. Edmund's House, Cambridge (CB3 0BN). (942)F

FELLOWSHIPS

THE UNIVERSITY OF SUSSEX

RESEARCH FELLOWSHIPS IN THEORETICAL ASTRONOMY

Applications are invited for up to two SERC-supported posts of Research Fellow in Theoretical Astronomy, for a period of two years with possible extension to a third year. The posts are on the Research Fellow IA scale (£7,190 to £11,615 pa). Appointments will be on the lower half of the scale. All posts carry USS benefits. Appointments will normally commence on 1st October 1984.

Candidates should propose an independent research programme related to that of existing members of the Centre. Further information can be obtained from Professor R J Tayler, Astronomy Centre, Physics Building, University of Sussex, Falmer, Brighton BN1 9QH, UK. Applications should arrive by 27th February 1984.

Applicants should ask up to three referees to send confidential reports, to reach the Astronomy Centre by the same date. (913)F

THE UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral research position (MRC-funded) to work on the interaction between tetanus toxin and neural tissue. The project will include studies on (1) the "receptor" for tetanus toxin (2) the biochemical and ultrastructural features of the internalization process and (3) structure function relationships within the toxin molecule itself.

Techniques involved will be in part similar to those previously developed to study the interaction of cholera toxin with target tissues (J Biol Chem 256 (1981) 8724), but will also involve the extensive use of monoclonal antibodies.

Applicants should have a PhD in Biochemistry or related discipline, and preference may be given to those with experience in cell culture and immunochemical techniques, and with an interest in membranes.

Salary: £7,190 to £8,080.

The position is immediately available although the starting date is negotiable, and will be for a maximum of 3 years.

Applications (along with the names of two referees) should be sent to Dr D R Critchley, Department of Biochemistry, University of Leicester, University Road, Leicester LE1 7RN. (939)E

THE AUSTRALIAN National University invites applications for a number of Postdoctoral Fellowships tenable for two years in the Research School of Physical Sciences. These are intended for young scientists under the age of 30 at the time of application who have completed, or expect soon to complete, requirements for a PhD degree or equivalent qualification. Appointments will be taken up during the second half of 1984 and may be made in any field of research of interest to the School which consists of departments of Applied Mathematics, Astronomy (Mount Stromlo and Siding Spring Observatories), Atomic and Molecular Physics, Engineering Physics, Mathematics, Nuclear Physics, Plasma Research Laboratory, Solid State Physics, Systems Engineering and Theoretical Physics. Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow Grade 1 $A20,164 — $A23,100; Postdoctoral Fellow Grade 2 $A23,394 — $A30,734 pa. Current exchange rates: $A1 = $US0.90 = UK62p. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should obtain further particulars from The Registrar, the Australian National University, GPO Box 4, Canberra, ACT 2601, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, before submitting applications which close on 31 January 1984. (W633)F

EMBL

European Molecular Biology Laboratory

PREDOCTORAL FELLOWSHIPS

The European Molecular Biology Laboratory is to award a limited number (6-8) of predoctoral fellowships for graduates wishing to study for a PhD at EMBL Heidelberg or its outstations at DESY, Hamburg or ILL, Grenoble. The areas of research in Heidelberg include membrane biology, cellular differentiation, analysis of the structure of membrane proteins and protein nucleic acid complexes and the structure and regulation of genes in procaryotes and eucaryotes. At the EMBL outstations the research centres on the elucidation of biological structures using either synchrotron radiation (Hamburg) or neutron beams (Grenoble).

To be eligible, candidates must hold, or anticipate receiving in 1984, a first or upper second class honours degree, a masters degree or a diplom in biological sciences, physical sciences or mathematics. Preference will be given to candidates from the member states of EMBL and EMBC namely: Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, United Kingdom.

Short listed candidates will be asked to visit EMBL (travel expenses reimbursed) for an interview. Those awarded predoctoral fellowships will be expected to begin working at EMBL in September 1984. The normal duration of the fellowships will be 3 years subject to annual review.

The closing date for completed applications is February 1st 1984. Successful candidates will be notified by the end of April 1984.

Application forms and a catalogue giving further information about the research at EMBL and the groups participating in the Laboratory's predoctoral programme is available on request from Dr J. Tooze, Predoctoral Programme, EMBL, Postfach 10.2209, 6900 Heidelberg, F.R. Germany. (W511)E

POSTDOCTORAL FELLOWSHIP PhD, or Equivalent — 2 yr position. To participate in active research program on inflammation, arachidonic acid metabolism in blood vessels. Salary $17,000. To begin Jan-June, '84. Send inquiries, curriculum vitae, and 2 references to: Michael A Moskowitz, MD, Harvard Medical School, Massachusetts General Hospital, Boston, MA 02114 USA. (NW147)E

VICTORIA UNIVERSITY OF WELLINGTON

New Zealand

UGC POSTDOCTORAL FELLOWSHIPS

In 1984 the University Grants Committe will award Postdoctoral Fellowships — 14 tenable for 1 year, 14 tenable for 3 years, on a national basis. Priority will be given to awards in current growth research areas in science in this country.

The University invites applications for these awards in the following areas: Biochemistry, Botany, Chemistry, Geology, Geophysis, Computer Science, Operations Research/Statistics, Physics, Zoology.

Conditions of Appointment and method of application are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or from Mrs M McCarthy, Personnel Office, Victoria University of Wellington, Private Bag, Wellington, New Zealand, with whom applications close on 10 February 1984. Late applications

MASSEY UNIVERSITY

Palmerston North, New Zealand

DEPARTMENT OF CHEMISTRY, BIOCHEMISTRY AND BIOPHYSICS

POST-DOCTORAL FELLOWSHIP

Applications are invited from chemists or biochemists for a position in the Department of Chemistry, Biochemistry and Biophysics to undertake research for one year commencing as soon as possible in 1984.

The appointee will be part of a team working on the development of new separation methods for large scale protein isolations. A feature of the research will be the use of reversed phase high performance liquid chromatography. The work has considerable commercial potential and is supported by research contracts from the Development Finance Corporation. The appointee could anticipate that additional funding might be available for a continuation of this position.

Emolument will be at the rate of NZ$ 21,660 p.a. inclusive of an allowance of up to NZ$ 3,033 for fares.

Further details of this fellowship and of the University, together with the general conditions of appointment may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or from the Registrar of the University, with whom applications close on 15 February 1984.

FYSSEN FOUNDATION
194, rue de Rivoli, 75001 PARIS

The Fyssen Foundation's general aim is "to encourage all forms of scientific enquiry into cognitive mechanisms, including thought and reasoning, underlying animal and human behaviour, into their biological and cultural bases, and into their phylogenetic and ontogenetic development."

1984 - 1985 FELLOWSHIPS

The Foundation will award a certain number of FELLOWSHIPS.

These fellowships are meant for the training and support of research scientists working in disciplines relevant to the aims of the Foundation such as ethology, paleontology, archaeology, anthropology, psychology, epistemology logic and the neurosciences.

The Foundation wishes to support, more particularly, research in such fields as:

ETHOLOGY AND PSYCHOLOGY: Nature and development of the cognitive processes in man and animals,

NEUROBIOLOGY: Neurobiological bases of cognitive processes and of their embryonic and post-natal development, as well as the elementary mechanisms they involve.

ANTHROPOLOGY-ETHNOLOGY: Study of cognitive foundations:
a) of the representations of the natural and cultural development,
b) of the technical systems developed in the various forms of social organization.

HUMAN PALEONTOLOGY: Origin and evolution of the human brain and human artefacts.

Priority will be given to French scientists wishing to work abroad and to foreign scientists wishing to work in French laboratories. Study grants will normally be granted for one year but may be extended up to three.

Applications should be established according to a form to be obtained from the Foundation which will include:
- the curriculum vitae,
- the *list* of publications of the applicant,
- the names of two senior scientists whom the applicant has asked to send testimonials to the Secretariat of the Foundation by the date indicated below,
- the letter of acceptance of the inviting laboratory.

The completed files should be sent in *15 COPIES* to the Secretariat of the Foundation, 194, rue de Rivoli, 75001 PARIS.

Limit date of receipt of applications: *APRIL 1st, 1984, without fail delivery date at the Foundation.*

1984 INTERNATIONAL PRIZE

A substantial INTERNATIONAL SCIENTIFIC PRIZE shall be given for a major contribution to the progress of knowledge in the fields of research supported by the Foundation. It was awarded in 1980 to Professor Andre LEROI-GOURHAN, in 1981 to Professor William H. THORPE, in 1982 to Professor Vernon B. MOUNTCASTLE and in 1983 to Professor Harold C. CONKLIN.

Disciplines considered for the 1984 Prize: *Cognitive psychology and Epistemology.*

The nominations should include:
- a curriculum vitae of the nominee,
- a list of his publications,
- a summary (four pages maximum) of the research work upon which the nomination is based.

Nominations for the 1984 Prize of the Fyssen Foundation should be sent in *15 COPIES* to the Secretariat of the Foundation, 194, rue de Rivoli, 75001 PARIS.

Limit date of receipt of nominations: *1st SEPTEMBER 1984.*

(W622)E

ANNOUNCEMENT

European Association for Cancer Research (EACR) — Italian Fellowship Programme in Cancer Research — Sponsored by the Italian Association for Cancer Research (Associazione Italiana per la Ricerca sul Cancro, AIRC)

Applications are invited from scientists and clinicians specifically in Europe to undertake cancer research projects in Italy. The Fellowships are designed to provide financial support for researchers to spend from 3 months to 1 year in Italian research institutions and the awards will include travel expenses to and from the host institution. The stipend will be related to age and experience and based upon national pay scales for academic research workers in Italy.

Proposed projects may be concerned with any aspect of research in cancer including chemical and viral carcinogenesis, epidemiology, tumour biology, biochemistry, genetics, immunology, immunotherapy, chemotherapy and radiotherapy. However, preference will be given to investigations on basic topics in cancer research.

Applicants should have worked actively in cancer research for at least two years and they should possess a doctorate degree or the equivalent. Applications should contain a curriculum vitae including a description of the proposed research project, details of travel expenses requested and a letter of approval of the proposed research project and invitation from the host institution in Italy.

The closing date for applications will be 1st April and 1st October of each year and the applicants will be notified of the award about 3 months following each closing date.

Please apply to the Secretariat of EACR at the following address for further details and application forms: Dr. M. R. Price, Secretariat of EACR, Cancer Research Campaign Laboratories, University of Nottingham, Nottingham NG7 2RD, UK. (W635)E

POSTDOCTORAL FELLOWSHIP IN NEUROCHEMISTRY

available for PhD or MD with training in analytical chemistry, especially HPLC. Work to be conducted on clinical research projects in Autistic children. NIMH stipend available beginning July or September 1984.

Interested applicants should contact Roland D Ciaranello MD, Laboratory of Developmental Neurochemistry, Department of Psychiatry, Standford Medical School, Stanford, CA 94305.
(NW166)E

THE QUEEN'S UNIVERSITY OF BELFAST

POST-DOCTORAL RESEARCH FELLOWSHIP IN ORGANIC CHEMISTRY

Applications are invited for a post-doctoral research fellowship to work with Professor R. Grigg on "New Prototropic Processes for the Synthesis of Heterocyclic Compounds". Appointment will be for one year with possible extension for a second year. Salary £7,632 per annum.

Applications, including full curriculum vitae and the names and addresses of two referees, should be addressed to the Personnel Officer, The Queen's University of Belfast, BT7 1NN. Closing date 31st January 1984. (945

EDINBURGH UNIVERSITY
POSTDOCTORAL FELLOWSHIP
Spin Dependent Effects in Low Energy Electron Atom Collisions

Applications are invited for a post of two to three years duration supported by the SERC from experimental physicists with experience in electron atom scattering. The successful applicant will be involved in a sequence of studies of spin dependent effects in the scattering of low energy electrons by atoms, making use of an existing source of polarised electrons.

Salary on the RG1A Scale (£8,080 — £8,975) with placement according to age and experience.

Enquiries and applications with the names of two referees to; Dr D M Campbell, Department of Physics, University of Edinburgh, James Clerk Maxwell Building, The King's Buildings, Mayfield Road, Edinburgh EH9 3JZ.

Please quote Reference No 5129.
(918) E

ISTITUTO NAZIONALE DI FISICA NUCLEARE (I.N.F.N.)

ONE FELLOWSHIP IN NUCLEAR PHYSICS

For one year, starting September 1984 for non Italian citizens. The chosen applicant shall pursue his research at the National Laboratories of Legnaro (Padua).

The main field of activity will be experimental work with the 16 MV Tandem Van de Graaff accelerator of the Legnaro Laboratories.

The salary will be approximately 1.000.000 Italian lire per month for twelve months.

Send applications and requests for further information to: Prof. Cosimo Signorini, Director of the National Laboratories of Legnaro, Via Romea, 4 — 35020 Legnaro (Padua) Italy.

The application deadline is February 15, 1984. (W626)E

SOUTHAMPTON PHLS and UNIVERSITY OF ALBERTA
Department of Medical Microbiology
POST DOCTORAL FELLOWSHIPS

Applications are invited for two Canadian funded positions for working on techniques relevant to the Southampton/North American Molecular Epidemiology Programme. The work will involve the development and evaluation of chromosomal and plasmid probes, endonuclease restriction analysis, plasmid detection and comparison by DNA homology, storage and media requirements for optimisation of molecular techniques.
The posts will relate (1) to the detection and strain identity of Campylobacter jejuni/coli/CLO/pyloridis, and (2) strain identity, antibiotic and antiseptic resistance of proteus species isolated from patients with hospital acquired infection.
Applicants should have an appropriate background in biochemistry, cell biology, immunology or relevant microbiology and be within 3 years of having, or about to obtain a PhD. The post is tenable for up to 3 years in the University of Alberta, Edmonton, Canada. Salary, Canadian $20,000. For further particulars contact Dr A. D. Pearson by telephone in the UK 0703 776177, quoting reference ME3.
No formal application forms. Please send three copies of full curriculum vitae, summary of PhD, names and addresses of three referees to the Director, PHLS, Level B, South Block, Southampton General Hospital, Southampton SO9 4XY, England by 10th February, for consideration March 1984. Appointment will depend on successful competition to an external agency. (931)E

FRIEDRICH MIESCHER-INSTITUT
Basel, Switzerland
RESEARCH FELLOWSHIP

A fellowship is available in a research group studying the role of oncogenes in human leukemogenesis. Appropriate technologies and good clinical contacts are available. We subsidize your travel costs.

Direct your application with CV, names of two referees to Dr Ch Moroni, Friendrich Miescher-Institut, PO Box 2543, CH-4002 Basel, Switzerland. (W628)E

THE JOHNS HOPKINS UNIVERSITY
DEPARTMENT OF EARTH AND PLANETARY SCIENCES
POSTDOCTORAL FELLOWSHIP IN STRUCTURAL GEOLOGY

The Department of Earth and Planetary Sciences seeks a quantitative structural geologist to fill a one-year postdoctoral fellowship (renewable). PhD required. Send resume and three reference letters, by January 31, 1984, to: Assist. Prof. Declan De Paor, Earth & Planetary Sciences, Johns Hopkins University, Baltimore, Maryland 21218. (NW172)E

The Wellcome Trust

Wellcome Trust Senior Research Fellowships in Medical Science in Australia

The Trustees of the Wellcome Trust announce the award in 1984 of 2 five year Senior Research Fellowships to be held in Australia in clinical medical science. Both medically qualified and science graduates, aged probably between 32-38, who wish to make their career in Australia and undertake research in a clinical or para clinical Australian University department are eligible to apply whether or not they are currently working in Australia. Direct personal enquiries by possible candidates are welcome but formal applications must be submitted by the Head of Department in the University where the candidate will work. Candidates will normally be Australian citizens.

The salary offered will be according to age and experience and on appropriate Australian academic scales, with up to $A10,000 p.a. ancillary support.

Nominations must be submitted on the appropriate application form and the closing date for the 1984 awards is 1 March 1984. For information and application forms please contact:

Dr Bridget M Ogilvie, The Wellcome Trust, 1 Park Square West, London NW1 4LJ England, or
Dr B Hudson, The Royal Australasian College of Physicians, 145 Macquarie Street, Sydney NSW 2000, AUSTRALIA.

(919)E

UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY
POST-DOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral research position (CRC-FUNDED) to work on an ongoing project directed toward clarifying the relationship between Tyrosine-specific phosphorylation of the cyto-skeletal protein vinculin, and the morphology of cells transformed by Rous sarcoma virus (RSV).

Methods involved will include cell culture (transformation of primary chick cells with RSV), immuno-chemical and immunofluorescence techniques.

Applicants should have a Ph.D. in Biochemistry and experience in some area of Tumour Biology is desirable.

Salary £7,190 to £8,975.

The position is available immed-iately, although the starting date is negotiable, and will be for 2 years.

Applications (along with the names of two referees) should be sent to Dr D. R. Critchley, Department of Biochemistry, University of Leicester, University Road, Leicester LE1 7RN. (938)E

ISTITUTO NAZIONALE DI FISICA NUCLEARE (I.N.F.N.)

TWO POST-DOCTORAL FELLOWSHIPS IN THEORETICAL NUCLEAR AND PARTICLE PHYSICS

For one year, starting October 1984, for non Italian citizens. The chosen applicants can pursue their research at any of the following Laboratories and Sections of INFN:

- National Laboratories of Frascati (Rome)
- National Laboratories of Legnaro (Padua)
- National Southern Laboratory (Catania)
- INFN Section of Turin
- INFN Section of Genoa
- INFN Section of Milan
- INFN Section of Pavia
- INFN Section of Padua
- INFN Section of Trieste
- INFN Section of Bologna
- INFN Section of Florence
- INFN Section of Pisa
- INFN Section of Rome
- INFN Section of Naples
- INFN Section of Bari
- INFN Section of Catania
- INFN Section of Sanità (Rome)

The annual gross salary will be 18.000.000 Italian Lire.

Send applications and requests for further information to: Prof. Nicola Cabibbo, President National Institute of Nuclear Physics (INFN) Piazza dei Caprettari, 70 — 00186 ROME (Italy).

The application deadline is February 28, 1984. (W625)E

AWARDS

Prize competition

announced by the

Anna Monika Foundation

for the investigation of the physical substrate and functional disturbances of endogenous depressions by approval of the Minister of the Interior of Nordrhein-Westfalen, Düsseldorf, 9th of June, 1965.

The Foundation announces the following prizes:

First Prize	**US-Dollar 15.000,-**
Second Prize	**US-Dollar 5.000,-**
Third Prize	**US-Dollar 2.500,-**

preferably for studies of biochemical, histological, neurophysiological, neuropathological, psychopharmacological, psychiatric or psychosomatic nature. The studies should be carried out in close cooperation with a psychiatric clinic, an university or an equivalent scientific institution. As far as possible, the papers should give information about recent advances in knowledge that should be helpful in promoting treatment and would open up new paths of progress. The papers may be written in German, French or English and should be submitted to the Chairman of the Committee, *Professor Dr. P. Kielholz, Basle/Switzerland.* Besides hitherto unpublished studies, papers published in the past two years in a German or international professional journal may also be submitted. *Deadline for submission to the Committee is 30th of September, 1984.* To help the Committee to come to a speedy decision it is requested that a maximum of three publications in four copies as well as a summarizing report (approx. 600 words) of the studies submitted for the competition should be included. *Prizes will be awarded on 30th of June, 1985.* If, in the opinion of the Committee, no papers of sufficient merit are submitted, it reserves the right to make no award. Prizes and their amounts will be awarded according to the merits of the study in question. Subject to the Committee's decision, each prize can be divided between two papers.

The Committee of Judges:

Chairman: Professor Dr. med. P. Kielholz, Psychiatrische Universitätsklinik Basel, Wilhelm-Klein-Straße 27, CH-4056 Basle/Switzerland

Members:

Professor Dr. G. Baumgartner, Neurologische Universitäts- und Poliklinik, Zürich/Switzerland.

Professor Dr. Otto Creutzfeldt, Max-Planck-Institut für Biophysikalische Chemie, Göttingen/Fed. Rep. of Germany.

Professor Dr. H. J. Dengler, Medizinische Universitätsklinik, Bonn-Venusberg/Fed. Rep. of Germany

Professor Dr. Alfred M. Freedman, Department of Psychiatry, New York Medical College Valhalla, New York/USA.

Professor Dr. K. Heinrich, Psychiatrische Universitätsklinik, Düsseldorf/Fed. Rep. of Germany.

Professor Dr. Albert Herz, Max-Planck-Institut für Psychiatrie, München/Fed. Rep. of Germany.

Professor Dr. H. Hippius, Psychiatrische Klinik und Poliklinik der Universität München/Fed. Rep. of Germany.

Professor Dr. Horst Jatzkewitz, Max-Planck-Institut für Psychiatrie, München/Fed. Rep. of Germany.

Professor Dr. Dr. Palm, Zentrum für Pharmakologie der Johann-Wolfgang-Goethe-Universität, Frankfurt/Main.

Professor Pierre Pichot, Chaire de Psychologie Médicale, Centre Psychiatrique Sainte-Anne, Paris/France.

Professor Dr. Dr. Wilhelm Stoffel, Institut für Physiologische Chemie der Universität Köln/Fed. Rep. of Germany.

Managing Director: Professor Dr. Benno Hess, Töllnerstraße 9/11, D-4600 Dortmund 1/Fed. Rep. of Germany.

nature is keeping ahead

Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

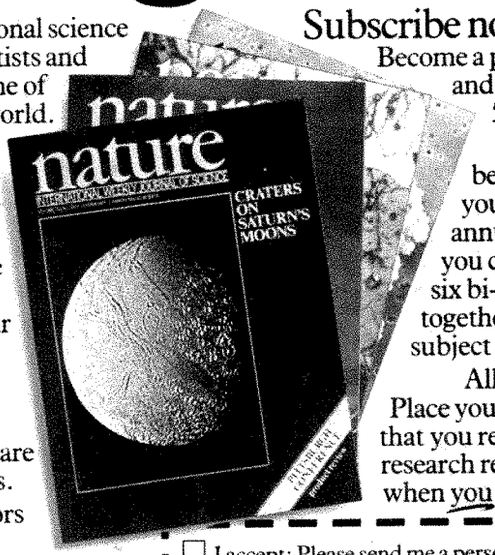
With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

A **News and Views** section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews – Eminent figures offer expert judgments on a wide variety of recent publications.



Special Issues providing an in-depth treatment of topics of importance.

Product Reviews – Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now – at Half Price

Become a personal subscriber now and you will receive a discount of 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just 94p a week. Place your order now and make certain that you receive the scientific news and research results crucial to your work when you want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special half-price rate of £49.00.

☐ I enclose my personal cheque for £49.00 made payable to *Nature*. (Note: Institutional cheques cannot be accepted at this special rate).

☐ Please charge to my credit card account.

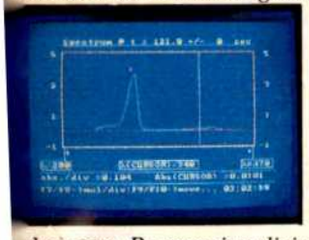
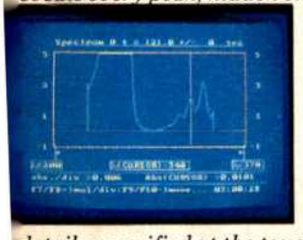
T MISS PEAKS

E ARRAY DETECTOR



ısh-button access to chromatograms and spectra, combined with an innovative cing technique, automatically surveys and explores the whole chromatographic ıdscape. Equips you with colour-graphic ed back for an analytical follow-through no her system offers. Power to track, expose d pinpoint all your peaks. Only LKB's Rapid ectral Detector lets you rapidly pursue, sily discover and clearly reveal every single ak—and then deliver it blown-up in perfect detail. So however small, or wherever it's hidden, you'll just never miss a peak—you just can't! The Rapid Spectral Detector is a computer based diode array detection system that offers dramatic breakthroughs in HPLC. With real time display and raw data storage Rapid Spectral provides the true visual command you need for complete analytical insight. Lets you probe new perspectives to give you more information and better results. So if you want to find those missing peaks, get in touch with LKB. We'll send you a broschure that describes the very best in diode array technology. You'll find it infinitely revealing, just like our Rapid Spectral Detector.



A computer generated contour map of the total absorbance pattern after separation. The vertical and horizontal axes are time and wavelength respectively. Colour coding is used to represent different levels of absorbance for each isogram.

ive the cursor through the isoıms to access chromatograms...

d spectra. Progressive slicing rapeveals every peak, hidden or not.

Packagene™ Extract System

- Frees up the time you now spend making packaging extracts. You can spend your time producing and analyzing data.
- Provides high efficiencies and consistent, reliable performance. The **Packagene** System routinely achieves packaging efficiencies of greater than 10^8 pfu/μg.
- Is more convenient to use than any other commercially available lambda packaging extract system. It's a single tube, to which only substrate DNA need be added.

The **Packagene** extract system is an efficient, single-extract *in vitro* lambda DNA packaging system. It is derived from a complementary mixture of induced *E. coli* strains (1, 2). These strains are lysogenic for lambda mutants, which are blocked at different stages of virus maturation. The extract contains all the components and buffers you need to perform the packaging reaction, and requires only the addition of substrate DNA.

Performance

Efficiency—A typical **Packagene** Extract System gives the following efficiencies in a standard packaging reaction using 0.5 μg of the indicated vector DNA.

DNA	Efficiency (plaque forming units/μg)
ligated lambda cI857 Sam7	2 x 10^8
ligated lambda 1059	1 x 10^8
ligated EMBL 3 or 4	1 x 10^8

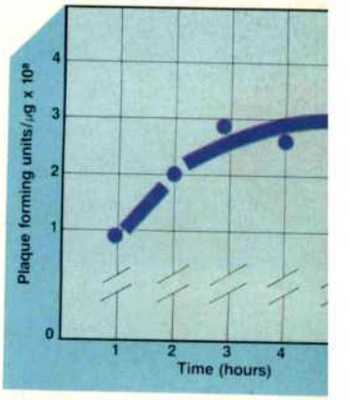

Figure 1. Time course analysis of a la packaging experiment. At time zero, C of lambda cI857 Sam7 DNA was add duplicate **Packagene** Extract System the times indicated one reaction at a was assayed for plaque forming units data indicate the **Packagene** System is complete after 3 hours.

Capacity: As much as 5 μg of DNA can be packaged in a sing **Packagene** extract system vial.

Low Background: The level of endogenous background plaqu the extract comprises less than .0001% of the expected phage

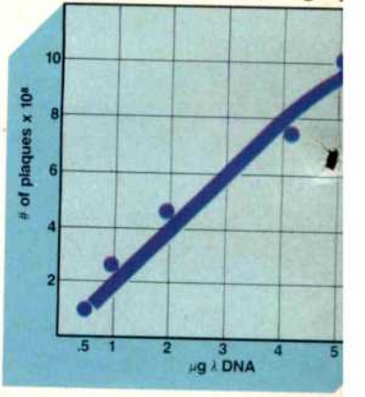

Figure 2. Analysis of the **Packagene** E System capacity. Different amounts of lambda cI857 Sam7 DNA were added t **Packagene** Extract System vials as indi After 2 hours the extracts were assayed plaque forming units. The increase in th number of plaques obtained is directly p portional to the amount of DNA adde 3-5 μg of DNA in each extract vial.

New! Eliminate the need to prepare lambda arms with the state-of-th EMBL 3 and EMBL 4 lambda vectors now available from Promega. Co us or one of our distributors for further information.

NATURE'S BIOREACTOR

The New Bio-Response MCT* (Mass Culturing Technique) System Delivers Monoclonal Antibodies And Other Mammalian Cell Products When You Need Them—From Grams To Kilograms.

Insufficient quantities of desired peptides are a key cause of expensive research and production delays. The MCT system is a *new* and *unique* mammalian cell culturing process designed to overcome the obstacle of insufficient quantities of peptides by delivering the quantity you need... *when you need it!* Additionally, every step in MCT production has been developed to contain costs now and in the future while maintaining exceptional purity and quality in mammalian cell proteins.

Quantity

Unlike conventional cell-culture methods, the MCT system uses "fresh," free-flowing lymph directly from a cow. Following treatment, the lymph is continuously diffused into and out of a growth chamber. This nearly *in vivo* growth environment stimulates continuous and optimal protein secretion. The result? Large quantities of desired proteins enabling you to move to the clinic or market... *faster.*

Cost

Unlike conventional cell-culture methods that require extensive labor forces and expensive growth mediums, Bio-Response's MCT is a closed, steady-state system. In essence, the MCT system starts with a low-cost lifeline—a feeding cow—and ends with a pure, quality product. MCT *...an optimal system at low cost.*

Purity

Unlike conventional cell-culture methods, the MCT system is designed to insure purity without tedious processing. By directing the lymph across semi-permeable membranes, MCT provides both separation of media protein from desired cell products, and a continuous nutrient flow. The ability to add or withdraw from the chamber to maintain optimal cell density permits continuous harvest of a highly pure product.

Quality

Unlike conventional methods of production that attempt to create biologically active mammalian cell products, the MCT system provides a pure-mammalian product—an exact copy of the original protein and, in the case of non-antibody polypeptides, uncompromised by inappropriate glycosylation and disulfide bond formation. There is a growing consensus favoring products produced in a mammalian cell-culture system, such as the Bio-Response MCT system.

Isolate DNA and RNA with CsTFA™ a new centrifugation medium

- Convenient isolation of nucleic acids
- Improves purity and quality
- Bands all types of RNA
- Inhibits nuclease activity
- Fewer phenol extractions
- Easy recovery by ethanol precipitation
- EtBr-free one-step plasmid isolation

Contact us today for more information on CsTFA and other high quality centrifugation media for nucleic acids, including optical and reagent grades of CsCl, or order directly from your local representative.

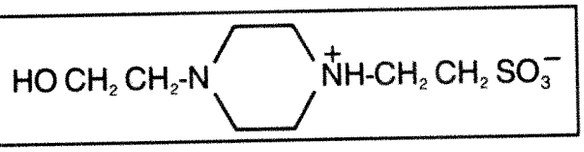
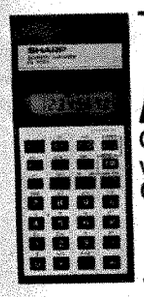
HEPES

THE MOST WIDELY-USED "GOOD" BUFFER IN PHYSIOLOGICAL & RELATED RESEARCH.



HEPES, with a pKa value of 7.31 at 37°C has become the most widely used of the "Good buffers" in physiological and related research. Its emergence is no surprise considering the shortcomings of the buffers commonly in use prior to the introduction of these zwitterionic buffers by N.E. Good and colleagues in 1966. The various systems in use up til that time have a variety of disadvantages which limit their usefulness and make them inconvenient in cell or tissue culture techniques. For example, the carbonate system has a pKa value more than a full pH unit away from that required for efficient cell growth. In addition, an atmosphere of carbon dioxide is required to maintain the pH of the media by minimizing CO_2 loss from the solution. Phosphate buffers tend to precipitate many polyvalent cations and have poor buffering capacity above a pH of 7.5. Tris buffers have a high coefficient of pH variation with temperature and are frequently inhibitory. For a thorough review of these and other commonly used buffer systems see Good et al.

HEPES on the other hand, with its pKa of 7.31 at 37°C, has its maximum buffering capacity very near the pH of mammalian systems. It exhibits no metal binding and has a low pKa temperature coefficient of −0.014/°C. HEPES is readily soluble up to 2.25 M at 0°C and HEPES buffer systems can be maintained open to the atmosphere.



The success of HEPES and other zwitterionic buffers in cell culture systems has led to their widespread use in many fields. Several examples include their use in: 1) improved methods for propagating influenza A2 (Hong Kong) virus and in routine methods for virus assay and identification, 2) improving methods for extending survival times during organ culture, 3) increasing post-freeze motility of cryogenically stored semen, 4) reducing loss of blood factor activity from freeze drying during preparation, 5) improving media for bacteria culture, particularly using MOPS and HEPES and 6) improving the quality of preservation and stabilization for cell components from plant and mammalian tissue prepared for electron microscopy.

U.S. Biochemical Corporation has been a major supplier of HEPES and other "Good buffers" since our inception. Consistency of our product is assured by rigorous quality control of each batch before it is approved for use, including a low UV absorbance specification as well as tests for residual halide and trace heavy metal contaminants.

50 years of the gold standard

In 1934 a lasting symbol of quality and purity was founded – AnalaR.

AnalaR quickly became accepted as the internationally recognised standard for analytical reagents. Today in its Golden Jubilee year of 1984 there are over 400 AnalaR reagents, of guaranteed purity and reliability, available through BDH, the largest and most research orientated manufacturer of laboratory chemicals and biochemicals in Britain.

Two Superior Color Indicators

Bluo-Gal

For cloning into the lac gene, choose Bluo-Gal, a histochemical substrate for β-D-galactosidase. As with the widely-used substrate X-Gal, lac⁺ bacterial colonies are blue in its presence. However, Bluo-Gal contains a unique chromophor that rapidly produces a darker blue color than X-Gal. BRL's exclusive Bluo-Gal is the ideal indicator for M13 cloning and whenever β-galactosidase activity is altered. Already an integral part of the BRL M13 Cloning System, Bluo-Gal now is available separately for the first time.

Circle No. 40 on Reader Service Card.

AMPSCREEN™

Use BRL's exclusive AMPSCREEN, and detect ampicillin-sensitive recombinant DNA-containing colonies in only 10 minutes without replica plating. AMPSCREEN is a sterile disk, sized to fit into a standard 85 mm petri dish, and treated with a chromogenic substrate. After the colonies growing on a petri dish are blotted onto AMPSCREEN, recombinant DNA-containing colonies remain blue, while non-recombinant ones change from blue to yellow. The complete color change takes place in less than 10 minutes.

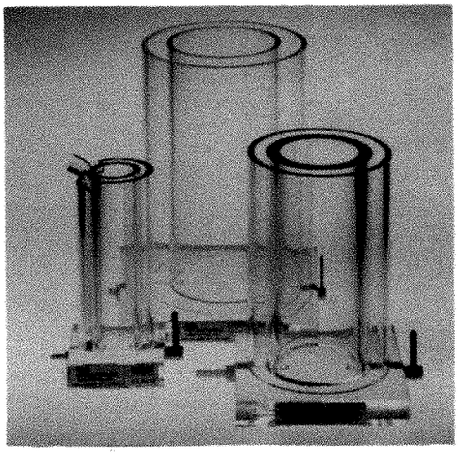
Circle No. 41 on Reader Service Card.

DNase I, RNase free

BRL DNase I is free of contaminating ribonucleases, making it ideal for isolating RNA. Isolated from bovine pancreas and purified to homogeneity by affinity chromatography, DNase I degrades DNA to oligonucleotides without degrading RNA or proteins. With each lot of DNase I, BRL provides exclusive lot-specific functional data specifying the amount of DNA digested by one μg of DNase I in one minute at 37°C.

Circle No. 42 on Reader Service Card.

Dpn I



5′-G^{Me}A$^{\downarrow}$T C-3′

3′-C T$_{\uparrow}$A^{Me}G-5′

The newest addition to BRL's line of high-quality restriction enzymes is *Dpn* I. *Dpn* I cleaves its recognition sequence *only* when the adenine is methylated, and is especially useful in isolating unmethylated DNA from a mixture of both methylated and unmethylated DNA. Isolated from a variant strain of *Diplococcus pneumoniae*, BRL *Dpn* I is purified free of contaminating nucleases and is qualified as a cloning-grade enzyme.

Save 15% on BRL Gradient Formers January 1 Through March 31, 1984

BRL Gradient Formers provide an inexpensive, easy-to-use means of generating accurate, highly reproducible gradients of aqueous fluids. The compact, concentric reservoir design makes it easy to match fluid heights and requires no cumbersome supports for precise leveling. Each gradient former is individually calibrated and adjusted to assure accurate linear gradients (± 1% of absolute linearity). In addition, concave, convex and exponential gradients can be readily generated. BRL Gradient Formers are available in three sizes, 150 ml, 750 ml, and 2 liter total capacities.

Circle No. 44 on Reader Service Card.

In-House Mycoplasma Detection and Identification

With MycoTect and MycoSpec, availab *exclusively* from BRL, you can detec and identify species of mycoplasma quickly, easily, and inexpensively right in your laboratory.

MycoTect is cytotoxic to mycoplasm infected cells. After incubation of cel samples with MycoTect and exposur to crystal violet, cell monolayers i uninfected wells stain more intensive ly and can be easily distinguished fron the sparse cell layers found i mycoplasma-infected wells. The entir process takes only five days—les than one fifth the time needed fo detection by conventional methods The cost of a MycoTect assay is only fraction of the cost of current tests and the only equipment needed is 24-well plate.

MycoSpec is a rapid, simple and inex pensive assay for the five majo mycoplasma species that account fo more than 95% of all laborator mycoplasma infections. Mycoplasm samples are incubated separately wit monoclonal antibodies to each of th five species, then with a biotinylate secondary antibody and finally with streptavidin-horseradish peroxi complex. The sample that stains diaminobenzidine is added co the monoclonal to the infectin species. With MycoSpec, identificatio is complete within five hours.

Circle No. 45 on Reader Service Card.

T4 Polynucleotide Kinase

Prepared by an exclusive new metho BRL Kinase is entirely free of co taminating endonucleases and exon cleases and is functionally free RNase. Each lot of BRL Kinase is fun tionally assayed for its ability to en label DNA fragments in both exchan and forward reactions, and data f these tests are provided with e order. BRL provides Kinase in solub form and, for the researcher's conv nience, guarantees the concentratio of each lot of enzyme at 10 units/μl.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

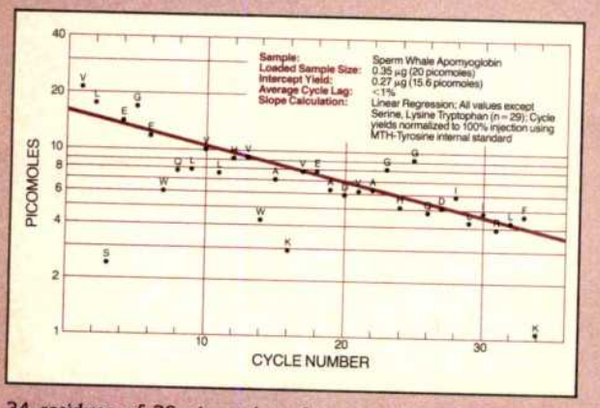
Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*



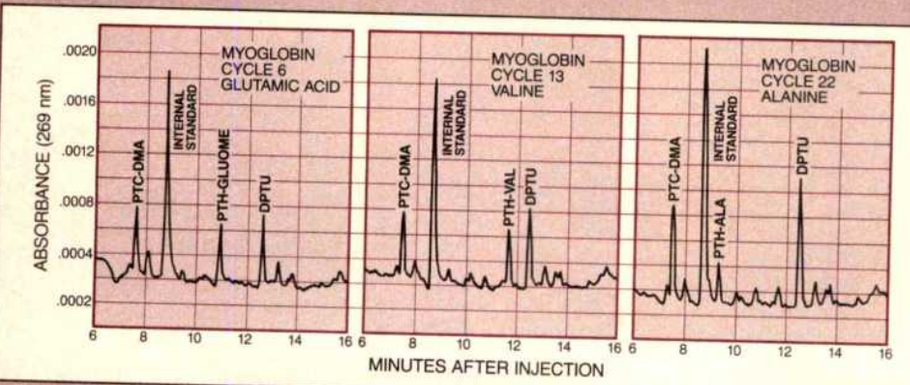
BIOSYSTEMS UPDATE

Gas-Phase Protein Sequencing

A Progress Report

Less than two years ago, Applied Biosystems introduced new gas-phase protein sequencing technology which, though in its infancy, set new standards of analytical performance and sensitivity. We are now pleased to announce the first in a series of improvements in chemistry, programming and hardware which begin to further realize the still untapped potential of the Model 470A Gas-Phase Protein Sequencer.

Changes in the coupling, cleavage and solvent extraction times, and use of an optional miniature sample cartridge, substantially increase repetitive yields and decrease lag on picomole level samples. Sequencer artifacts which can interfere with high sensitivity PTH-AA chromatography are also reduced by a factor of three to five.



34 residues of 20 picomoles of sperm whale apomyoglobin. Repetitive yield is 96% calculated from the least squares linear regression plot of individual amino acids quantitatively recovered at each sequenced cycle. Lag averages less than 1%/cycle.

The improvements are particularly dramatic with peptides. A user evaluating our new chemistry has reported sequencing the octapeptide angiotensin II to completion with only 25 picomoles of sample.

A new miniature PTH conversion flask increases typical PTH-AA recovery to greater than 95%. The improvement is most significant on serine, threonine and tryptophan since drying times are reduced threefold.

Best of all, these improvements, and others still under development, are designed to be compatible with every instrument we've built so our current users will continue to be at the leading edge of protein sequencing technology. The 470A Gas-Phase Protein Sequencer is capable of setting even higher performance standards and Applied Biosystems, in collaboration with many of our users, is continuing to investigate further improvements to this remarkable instrument. If you'd like more information, please circle number 8.

Actual HPLC chromatograms, without background subtraction or data enhancement, of residues 6, 13 and 22 from sequencing analysis of 20 picomoles of sperm whale apomyoglobin. The data illustrate the low background and high sensitivity of the Model 470A Gas-Phase Protein Sequencer.*

*Chromatography: IBM Cyano Column. Internal Standard: MTH tyrosine. PTH yields normalized to 100% injection: Cycle 6 (glutamic acid)—11.7 pmol, cycle 13 (valine)—9.1 pmol, cycle 22 (alanine) 6.2 pmol. PTC-DMA, phenylthiocarbamyldimethylamine; DPTU, diphenylthiourea.

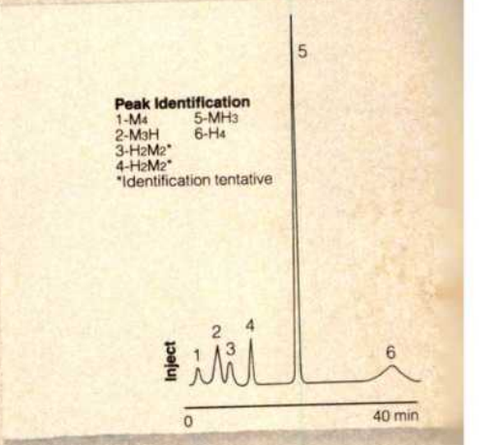
Now isolate and analyze proteins faster, with higher resolution and recovery.

Waters HPLC systems with new ion exchange, gel filtration and hydrophobic packings for biological separations.



High speed gel filtration separation of insulin.

Total recovery of enzymatic activity from a crude bacterial extract using ion exchange.

High resolution ion exchange separation of isoenzymes.

Separation time: 12 minutes.

Waters new high speed gel ltration methods allow rapid ractionation of protein samples. his same gel filtration method lets ou profile sample composition, olate all components and verify ne purity of collected fractions.

ample: 10 µl Insulin, 5 mg/ml
Column: PROTEIN-PAK 125
luent: 0.1% Trifluoroacetic Acid, pH 2.1
low Rate: 1.0 ml/min
etection: 214 nm, 0.5 AUFS

100% recovery of biologically active protein.

The large pore size of Waters polymeric ion exchange packings (1,000 Å) gives you recoveries of enzymatic activity approaching 100% for even high molecular weight enzymes.

Sample: 100 µl Bacterial Extract, 3 mg/ml
Activity: Glucose-6-Phosphate Dehydrogenase
Column: PROTEIN-PAK DEAE 5PW
Gradient Conditions
Eluent A: 0.02M Tris HCl, pH 8.5
Eluent B: 0.02M Tris HCl, pH 8.5 + 0.5M NaCl
0-100% B, curve 6, 25 min
Flow Rate: 0.5 ml/min
Detection: 280 nm, 0.1 AUFS
Specific Activity Increase: 4.9
Activity Recovery: 100%

Complete resolution of LDH isoenzymes.

The resolving power of Waters high performance ion exchange packings provides resolution of the closely related isoenzymes c lactate dehydrogenase.

Sample: 100 µl LDH Isoenzymes, 1 mg/ml
Column: PROTEIN-PAK DEAE 5PW
Gradient Conditions
Eluent A: 0.02M Tris Acetate, pH 8.0
Eluent B: 0.02M Tris Acetate, pH 8.0
+ 1.0M NaOAc
0-100% B, curve 6, 45 min
Flow Rate: 0.5 ml/min
Detection: 280 nm, 0.05 AUFS

Add the performance of Waters HPLC to your separations. And achieve greater success in protein isolation and analysis.

For a demonstration or additional information, contact your local Waters representative or call 617-478-2000 (X 2665).

Concentrate 200 Samples without BUMPING and achieve 100% sample recovery

Most laboratories report to us that they never realized how much sample they were losing until they used "Speed Vac"... The ease of sample preparation is also a big advantage... Place your samples in individual tubes or vials and turn "Speed Vac" "ON"... No cross contamination, no losses, no creeping, no foaming and the samples will be concentrated at the bottom of the tube...

How else can you concentrate "1 or 200" samples with such ease and efficiency.

- **HPLC** sample preparation where a dried, concentrated sample is important.
- **GLC** sample preparation... as above.
- **PHOSPHOLIPID** separation by HPLC — total evaporation of Acetonitrile — Water Solvent.
- **INTERFERON** purification by dialysis and evaporation.
- **TRI-CYCLIC** anti-depressant drug blood levels measured after a series of extractions and evaporations to dryness.
- **HORMONE** and Enzyme assays.

The Superpower in Power Supplies for Electrophoresis

All the power you need for today's electrophoresis applications can now be generated by a single power supply—the Bio-Rad Model 3000/300.

This one-of-a-kind power supply provides the following high outputs:

- Constant voltage to 3000 volts
- Constant current to 300 mA
- Constant power to 400 watts

Here are a few of the key electrophoresis techniques you can perform with the high outputs from the Model 3000/300.

High voltage: high performance electrofocusing (HPEF) in ultra-thin polyacrylamide gels.

High power: DNA sequencing

High current: protein electroblotting

Being brand new, this power supply has many convenience features. These include three independent digital readouts, so that voltage, current, and power are displayed simultaneously. And a crossover feature that ensures maximum resolution and minimum run time and prevents gel overheating.

Of course you're concerned about safety and so are we. Model 3000/300 conforms to all relevant safety standards to protect both the operator and the instrument.

On a price/performance basis, the Model 3000/300's price tag is the best in the industry. You can't beat it from any standpoint.

For more information about the single most useful power supply ever, contact:

Attention all biophysicists, molecular biologists and biochemists!

Biomembrane Structure and Function

Edited by
DENNIS CHAPMAN
Professor of Biophysical Chemistry
Royal Free Hospital
School of Medicine, London

Volume 4 in the TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY Series
Series editors:
Professor Watson Fuller, Dr Stephen Neidle and Professor Tony Atkinson

The application of physical techniques – such as X-ray diffraction and Raman spectroscopy – has revolutionised much of our thinking on the structure and function of membranes. In this important new study, contributors of international standing review a topical selection of approaches to the elucidation of **biomembrane structure and function.** The emphasis, throughout, is on the in-depth analysis of recent experimental work.

Published January 1984 Price £50.00 432pp
ISBN 0 333 31869 2

Contents

Calorimetric studies of model and natural biomembranes – *Diana Bach*, The Weizman Institute of Science, Israel; X-ray diffraction and electron microscope studies of the molecular structure of biological membranes – *Lee Makowski and Jade Li*, Columbia University, USA; Raman spectroscopy of lipids and biomembranes – *Surendra P. Verma and Donald F.H. Wallach*, Tufts-New England Medical Centre, USA; Infrared spectroscopic studies of model and natural biomembranes – *Ralph L. Amey*, Occidental College, USA and *Dennis Chapman*; Rotational and lateral diffusion of membrane proteins as determined by laser techniques – *Winfried Hoffman*, NUKEM GmbH, E.Germany, and *Colin J. Restall*, Royal Free Hospital, London; Theoretical models of monolayers, bilayers and biological membranes – *David A. Pink*, St Francis Xavier University, Canada; The Ca^{2+} dependent ATPase of sarcoplasmic reticulum – *G. Inesi and M. Kurzmack*, University of Maryland, USA.

Genetic engineering

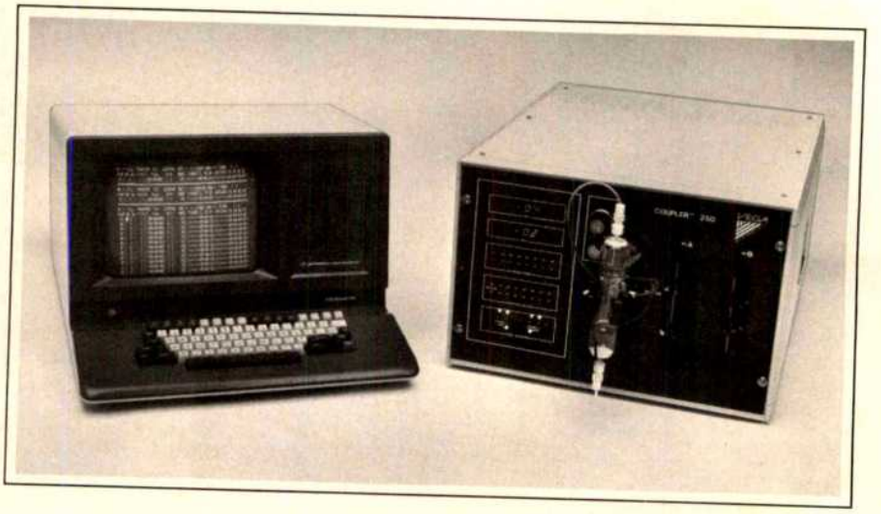
Building blocks and Reagents for a leading technology

Protected nucleosides and nucleotides for the synthesis of oligodeoxynucleotides according to the phosphotriester method and the phosphite triester method

- 5'-OH protected nucleosides
- 3'-OH protected nucleosides
- 3'-phosphate and 5'-OH protected nucleotides
- 3'-phosphate duplex protected nucleotides
- Fully protected phosphoamidites (morpholido)
- carrier bound protected nucleosides as starter for solid phase synthesis

Chromatographically pure and subject to application tests

Special reagents for coupling condensation and selectively splitting off protective groups



Please ask for our detailed information

Federal Republic of Germany

What do Scripps, Revlon, Fujiya, and Syntex have in common?

Vega synthesizers.

Fully automated peptide synthesizers.

The most reliable and economical peptide synthesizers available.

That's saying a lot for our systems. But they do a lot. For Scripps, Revlon, Fujiya, Syntex and scores of others.

Take the Coupler™ 250. Microprocessor controlled with floppy disk storage. Dependable. Easy to program. Capable of operating up to four chemistry modules with just one microprocessor. Around the clock, if you want. Without missing a coupling.

Or the Coupler™ 296. Rugged. Large capacity. Able to produce quality peptides on a massive scale. All with the same reliable sophistication as the Coupler 250...only bigger.

There's more, too. Chemically-inert plumbing. User programmability. Pre-formatted synthesis software. A 1 year warranty on parts, 6 months on labor. And remarkably low prices.

So if you're looking for an automated peptide synthesizer, follow Scripps, Revlon, Fujiya, and Syntex.

Choose Vega.

You'll be in good company.

The transfer membranes with a memory.

GeneScreen*Plus*™

GeneScreen*Plus*™ is the new transfer membrane that gives you not only highest sensitivity and excellent band resolution, but trouble-free handling as well.

The slight natural curl of the membrane makes it easier to select from the package and easier to place on a moist surface. After drying it returns to its original shape to remind you which side is carrying the bound material. Wet or dry, GeneScreen*Plus*™ is highly resistant to cracking, distorting, tearing, or shrinking.

Binding of all sizes of DNA is so strong you don't need to waste time baking the membranes. No need for refrigeration either; just keep the box handy on the shelf.

Colony/PlaqueScreen™ Discs

Colony/PlaqueScreen™ Discs have all of the performance and convenience features of GeneScreen*Plus*™ and are precut to culture dish sizes. The gentle curl of the discs makes them easier to place on the agar plate without smudging, and moisture causes them to lie flat with minimal air entrapment. Removal is easier too, because they are strong and tear resistant.

Our Applications Laboratory is available to answer your questions about hybridization methods using either of these products. Meanwhile we'll be glad to send you detailed information on their performance characteristics. Simply call New England Nuclear or circle the Reader Service Number.

Unesco's crisis is for all of us

The US withdrawal from Unesco is intelligible and may be wise. The remaining members should abandon gentility in the hope of winning overdue reform. Unesco alone is not the worry.

DISMAY about the proposed withdrawal of the United States from the United Nations Educational, Scientific and Cultural Organization (Unesco) is natural. Especially when the US Administration is more than usually insensitive to the needs of collaboration overseas, the prospect that the United States may withdraw from a surviving network of international collaboration must be a matter for regret. But those in Washington who have been wringing their hands about the proposed withdrawal (see p.98), officers and officials of the National Science Foundation and the National Academy of Sciences, should not go too far, or they will find themselves in the same case as those, in the 1930s, who applauded Mussolini because he had arranged that Italian trains should run on time. The fact is that the US withdrawal from Unesco has been decided for reasons that have nothing to do with the organization's scientific programme and that, if valid, not merely justify the withdrawal but make it necessary.

For the past three years, the central complaint against Unesco has been its espousal of what it calls the "new world information and communications order", NWICO for short. This notion, which has been rumbling about in Le Corbusier's building in Paris since 1972, is a vivid illustration of the mischief that can be done when people set out to translate good but ill-defined intentions into rules that the whole world is then expected to follow. The argument has gone like this. Free speech is a common good, right? *Of course.* So everybody should be free to communicate, right? *Well . . . yes.* But it's not like that, because the world's successful news agencies and television networks are mostly owned by capitalists and put out distorted information about countries against which they are prejudiced but which lack the means to answer back; so should there not be some way in which governments not in control of international news agencies or television networks can influence what is said about them by others, and in the meantime should not journalists operating internationally be licensed by those about whom they would write? *Well . . . no.*

Doublespeak

Unesco's remedy would be worse than the disease it is meant to cure. To regard as synonymous the principle of free speech for people and the doctrine of information control by governments is, in *1984* language, doublespeak. To nurse the ambition, as Unesco has done for the past few years, to embody this mischievous obfuscation in some kind of international convention would run flatly against its own objectives of helping to make the world a more civil place. Unesco's management has been obtusely unwilling or unable to see the difficulty, citing the acknowledged imperfections of news agencies, newspapers and television networks as proof that something should be done. It has steadfastly refused to understand that many of its member governments, but especially that of the United States, are constitutionally bound to the view that the imperfections of the international press, in any case remediable by means other than NWICO, are the price that must be paid for free speech. To general surprise, the management seems to have soft-pedalled on the issue at Unesco's General Conference in Paris last November, even accepting a British gloss on the description of NWICO as an "evolving and continuous process", which is apparently a diplomatic device for making sure that the new order cannot now be brought in by *fiat*. Yet the issue has not gone away, and those remaining within Unesco will be battling with it for years to come.

If the State Department's calculation were that pulling out of Unesco is the best way of making sure that this tedious matter does not rear its head again, or that the threat of doing so may be the most effective way of changing Unesco's management, the loss to the scientific community would be a small price to pay — as would have been unpunctuality on the Italian railways in the 1930s for some other kind of political leadership than that provided by Mussolini.

The weakness in the position the United States has taken is threefold. Resignation would have been more convincing at the end of 1982, when the row about NWICO was at its height, than now, when the issue seems to have gone off the boil. In present circumstances, it is hard to tell to what extent the decision reflects the general impatience with United Nations institutions that keeps bubbling up within the administration. And there is bound to be a suspicion that resignation from Unesco, or the threat thereof, is an early move in November's presidential election campaign. If it wishes to avoid the shabby conclusions to which these suspicions point, the State Department should quickly give substance to the hints it has been dropping in Washington and put up the money that will be needed before the end of the year if the important parts of Unesco's programme are not to founder. The need that the International Council of Scienfific Unions (ICSU) should not be endangered typifies what must be done.

Disenchantment

There is also an urgent need that the State Department, and the US Administration as a whole, should come to a clearer and more guileful understanding of the reasons why its relations with UN organizations have become so irksome. One is that the United States has allowed its discovery in the 1940s that the United Nations did not obviate the need for international organizations, its alarm at the total cost (to which it is the chief contributor) and its dislike of being bested by the political manoeuvrings of its critics, to engender a disenchantment and a detachment that only exaggerates legitimate discontents. The United States would be better advised to define what is wrong and to seek to put it right.

There are general complaints against the UN system as a whole, and particular complaints against specific UN agencies, all of which unhappily apply to luckless Unesco. First, the agencies are needlessly bureaucratic, with decisions on minor matters rubber-stamped (or sometimes capriciously overturned) by officials in a complicated hierarchy whose exaltation and competence are often imperfectly correlated. Second, and not simply as a consequence, many of the agencies are outrageously expensive ways of accomplishing inexpensive tasks. Third, the agencies are often disastrously politicized, which means that issues entirely irrelevant to the objectives of an agency (such as whether Israel should continue as a member of the World Health Organization, a bone of contention three years ago) dominate proceedings. In this connection, it is only proper to acknowledge that Unesco's concern with the international traffic in information is not irrelevant to its terms of reference, although a majority of Unesco's member governments are guilty of imprudence for having used their voting power to advance the issue, just as it was shabby of them to use the same voting power to lift the minimum number of a member's nationals whom Unesco must employ from four to five.

0028-0836/84/020095-01$01.00

© 1984 Macmillan Journals Ltd

All of these complaints are legitimate, but can be sensibly assessed only against the knowledge that the UN system and its agencies are the only systematic means by which nations with very different interests are regularly required to meet each other. In recent years, the process has done very little to sustain the hope of the United Nations' founders that the system would somehow abolish conflicts large and small, but it has become a powerful channel for the flow of multilateral technical and material assistance from developed to developing countries, itself an indispensable complement to what countries are able to do bilaterally. Latterly, the UN system has become indispensable (if infuriating) as the only systematic meeting ground between the two kinds of governments. The value of all this is not negligible even if the present cost is too high.

Moreover, the complaints against the United Nations and its agencies are not irremediable, as the performance of the more efficient agencies shows clearly enough. The World Meteorological Organization is top of most people's lists of good performers, the International Atomic Energy Agency plays an indispensable part in the administration of the Non-Proliferation Treaty, the International Telecommunications Union is indispensable (if too much a prisoner of national telecommunications monopolies and thus in need of reform), the Tropical Diseases Programme of the World Health Organization has surprised the sceptics by having emerged as a sensibly directed programme of research and development and not the slush fund that seemed in prospect ten years ago. Arranging that Unesco should function that well is bound to be difficult, given that this agency's terms of reference are more fuzzy than any other's, but there is much that can and should be done to simplify Unesco's housekeeping.

The administrative problems should be more easily soluble than most Unesco delegates will allow. The bureaucracy and high cost, consequences though they are of the way in which the United Nations and its agencies are instruments of the collective will of member governments, should with wit and perseverance be remediable. Unesco as it has become is two things — a talking shop and an executive agency. It is inevitable and even proper, within the agency's terms of reference, that all member governments should feel free to have their say on grand matters of policy, but intolerable and unnecessary that the same should apply to the selection of people who should benefit from training programmes in special fields, or to the management of collaborative scientific programmes of the several kinds on Unesco's books. For an agency whose ambitions forever outstrip resources and even common sense, but whose staff is bloated by the small army of professional people hired to second-guess hostile governmental delegations, the sensible and frugal course would be to delegate much of this work. The International Council of Scientific Unions, already a powerful source of help to Unesco (but which antedates it) could for example take over much of what is intended. Then at least there would be some hope that the overhead cost, which often amounts to a third or more of what Unesco has to spend on its programmes, would be reduced.

Puzzlement

Many other Unesco projects should, on the other hand, be promptly brought to an end. Even in the relatively tangible field of science and technology, it is hard to see why Unesco is planning to spend $85,000 this year on helping member states to draw up "national programmes for research in biotechnology and its applications", and hard to imagine what special expertise it pretends to have in this competitive field. It is similarly mystifying that it should wish to spend $89,000 to help national governments to work out strategies for the development of information technology (or "informatics" in Unesco language). If there were even the most meagre evidence that member governments were anything but over-aware of the opportunities in these fields, the modest sums involved might be forgiven, but as things are they will literally be wasted. Unesco, unfortunately, has never been able to exercise self-restraint but instead feels bound to jump on every new bandwagon that comes along, usually with too small an amount of money to be decisive, often with too woolly an idea of what might be done to be helpful and sometimes with the ill-concealed intention of stealing other people's thunder so as to be able to magnify its own appearance on the scene.

But how can an incorrigibly expansionist organization such as Unesco be made to behave more sensibly? Those member governments dismayed by such developments must not underestimate their power. While the massed votes of the developing countries in the group of 77 (misnamed because there are many more of them) can almost always force the general conference to accept unpalatable proposals, particular wrongheadedness can be rooted out whenever delegations dig in their heels, abandon the customary gentilities of UN meetings which require that the chairman of every committee should be applauded for his eminence and congratulated for his wisdom, throw out the dangerous notion that a nonsense will become sensible if enough people vote for it, and simply declare that they will not be parties to proposals that they know to be objectionable. That, of course, would demand more of delegations than they have in the past been able to provide. The present crisis springs from members' past neglect.

Politicization

The politicization of Unesco is a more difficult problem, although not very different in its essentials. The first need is that all member governments should recognize that an organization with such wide terms of reference cannot be apolitical. If Unesco's programme on the free flow of information had not turned out to offend North America and Western Europe, it would no doubt have caused similar offence to the governments that practise censorship. Yet who will say that the free flow of information is not relevant to the interests of a body with science, education and culture in its title? The now-complainant governments have weakened their own positions in the past by failing to anticipate that such conflicts are unavoidable, to argue with conviction that there are two sides to most of the coins turned up — and then to insist on what is plain for all to see, that neither Unesco nor any other such representative body is equipped to be a negotiating forum for the removal of irreconcilable differences.

The second need is somehow to neutralize the irresponsible use of the votes of the group of 77, both in Unesco and the other UN agencies. Here again, the complainant governments are not nearly as powerless as they think. If, as this year, Unesco is determined to hold a major conference on the future development of information technology of which those with the most to contribute disapprove, they have a simple remedy — simply not to participate. If the massed votes should commit Unesco to a resolution calling for the restoration of all cultural property to its place of origin, or to a demand that intellectual property should be freely available to some class among the membership, they can do more than merely decline to cooperate — they can, more openly than has been their habit, argue for the notion that equity is not unidirectional. The complainant governments have in the past been too unreflective in their response to the demand that all countries should at all times be qualitatively equal, when the best that can be hoped for is dynamic diversity. Plain speaking is again the answer.

The future for Unesco is in all the circumstances not nearly as gloomy as the threatened withdrawal of 27 per cent of its budget would suggest. The ideal is that the hard times ahead should persuade the organization and its member governments that three-quarters of the budget is ample to support the present programme. Only last week, the director-general was asking his staff to reduce spending by 10 per cent this year — nearly half the battle. The complainant governments not planning to withdraw know what they have to do to encourage him in this direction — be less polite and better-informed. The United States should plan seriously to practise what Mr George Schulz promised in the State Department's letter of resignation — that the United States will collaborate with Unesco in (and help pay for?) those programmes it approves of. The important need is that disenchantment with Unesco should not infect US policy to the rest of the UN system. □

Monoclonal patent disputed

Disclosure threat to Japanese rights

Washington

THE Wistar Institute's efforts to patent monoclonal antibodies have run into trouble in Japan and the United Kingdom. Twenty-seven separate challenges have been filed in Japan to a Wistar patent for monoclonals that specifically attack tumour cells. The patent is based on research by Hilary Koprowski and Carlo Croce of the Wistar Institute and was assigned to Wistar by the researchers. And the British Patent Court recently affirmed the rejection by the Patent Office there of a second patent that covers monoclonals specific for viral antigens. Both have been successfully patented in the United States.

The challenge to the tumour antibody patent in Japan may prove the more costly of these setbacks to Wistar. A test kit that makes use of the antibodies for diagnosing solid tumours is already on the market in Japan, and Wistar has already sold three licences to the US patent. Clinical trials of anticancer agents that use the antibodies to home in on tumour cells are under way in the United States. Although Wistar's associate director, Warren Cheston, says that "realistically" he expects the patent to bring in less than $100,000 a year to the institute, he acknowledges that "if you believe the people on the commercial side, there's potentially huge sales out there". Cheston points out that the non-monoclonal diagnostic for colo-rectal cancer now in use is a multi-million dollar market.

Those challenging the patent are basing their case largely on an article that appeared in *Nature* the day before the US patent application was filed. The US patent is not threatened by the Japanese challenge, but the US filing established the priority date of the invention. And unlike the United States, which allows an inventor to apply for a patent up to a year after disclosing his invention, Japan (like Western Europe) demands "absolute novelty" — no disclosure before the first filing. The patent was filed for in the United States on 28 April 1978; in the 27 April issue of *Nature*, a News and Views article appeared with a brief description of Koprowski's work.

According to Helmuth Wegner, a Washington patent attorney who is representing one of the challengers, that disclosure, even if it is no more than "a fairly broad suggestion", is enough to invalidate the Japanese patent. The *Nature* article provides no experimental details; it notes in a single sentence that Koprowski had produced hybridomas that secrete antibodies with tumour-specific activity. The legal issue is whether that disclosure is in theory sufficient to allow someone else to duplicate Koprowski's work with a reasonable amount of experimentation.

Another tricky issue is sure to be the exact date that the *Nature* disclosure is considered to have taken place. The magazine would have been available in *Nature*'s London office on 26 April, and would have been posted to subscribers on that day. The Japanese law defines disclosure to have occurred when the publication is "distributed", a term not yet tested in court.

The report referred to (*Nature* **272**, 751; 1978) is by Dr Elizabeth Simpson of the Medical Research Council's National Institute of Medical Research at Mill Hill, London, and describes the proceedings of a workshop organized by M. Potter and F. Melchers at the National Institutes of Health on 3–5 April 1978. Simpson refers to the production of monoclonal antibodies against "Differentiation and tumour antigens" by "several groups", and says that Koprowski, using human cancer tissues as a source of antigens, had been able to produce monoclonal antibodies which reacted with human cells so as to "suggest that some of them may be against tumour-specific antigens".

If the challenges are upheld, Wistar would lose the Japanese market, which is the second largest pharmaceutical market in the world. Patents in North America and West Germany would not be affected.

The British patent covered the work by Koprowski, Croce and Walter Gerhard on monoclonal antibodies specific for viral antigens. The Patent Office had earlier ruled that the work was an obvious application of the basic procedures for producing monoclonal antibodies developed several years earlier but never patented by César Milstein and Georges Kohler of the Medical Research Council's Laboratory of Molecular Biology. The Patent Office noted in particular an article that had appeared in *The Lancet* — before the filing of the Wistar patent — that suggested a number of possible uses for monoclonal antibodies, including the detection of viral antigens. Wistar, which had little difficulty obtaining broad patent protection in the United States and several European countries for the viral antibodies, appealed against the rejection; late last year the patent court ruled in favour of the Patent Office.

Stephen Budiansky

European forests

Pollution, pathogens and pests

FORESTS in the Federal Republic of Germany (FRG) and many other parts of Central Europe are deteriorating rapidly. It is estimated that in West Germany 34 per cent of all forest, which covers 27 per cent of the country's total land area, is already damaged. The city of Augsburg has created a special nature park to inform its citizens about the advancing disaster and the Christmas tree business has languished. Whereas in 1982 damage to conifers was estimated in Bavaria at 10-30 per cent, the official figure is now 60 per cent for Scots pine (*Pinus sylvestris*) and 80 per cent for fir (*Abies*). Furthermore, 44 per cent of the beech forest is showing signs of distress.

The situation in Switzerland, where the first symptoms were reported at the Federal Institute of Forest Science in early 1983, has deteriorated rapidly, exacerbated by heavy snowfalls and storms in the two previous winters. The first signs of distress were shown by *Abies alba* in the eastern and northern plateau that includes Berne, the Bodensee and the most heavily populated areas. Three months ago, reports came in from the southern Alps of damage to spruce (*Picea excelsa*), the dominant species, between 1,000 and 1,800 m altitude and in November of massive damage in some localities.

In Czechoslovakia, 11 per cent of the forest is said to be destroyed and a further 11 per cent dying. A recent ecological report by the Czech Academy of Sciences, which was not published in Czechoslovakia but a copy of which reached the French newspaper *Le Monde* through the human rights organization Entraide et Action, draws a grim environmental picture that forecasts that 45–60 per cent of the nation's forest will be degraded by the end of the century.

Although most of the damage is caused by "acid rain", two serious forest pests are adding to the toll. In Switzerland, winter weather damage was followed by an exceptionally hot summer in 1983. Attacks by the bark beetle *Ips typographus* L. reached serious levels. This beetle normally produces two generations per summer, but in 1983 it produced three. This winter so far has been exceptionally mild and the beetle will overwinter in serious numbers if the normal cold fails to occur. In the stressed environments at high altitudes, regeneration of forest is slow and the Swiss institute is seriously concerned that the threatening deafforestation will lead to erosion and avalanches.

In Poland, the moth *Lymanthia monacha* (the black arches moth) known in German as *Die Nonne* (the nun) is said to be the major cause of damage. Historical accounts exist of this moth occurring in devastating swarms from Europe through Central Asia to China and Japan, killing large areas of both conifer and broad-leaved forest, until it eventually succumbs to its own disease.

French research support

More clout for CNRS

FRENCH university scientists should be bracing themselves for a radical new year. Last week, the Council of Ministers, the French cabinet, considered the programme of the Centre National de la Recherche Scientifique (CNRS), the body that supports most basic science in France, and has publicly approved of it.

Why should the council do that? To give CNRS political weight in dealing with ministries other than the ministry of research and industry, to which it belongs, says Pierre Papon, CNRS director-general. Among those ministries is the ministry of national education (MEN), responsible for the universities.

CNRS will be restructuring its relationship with the universities in 1984, says Papon. The 75 universities of France are "too many", which has led to a "balkanization" of university politics. According to Papon, CNRS will in future no longer be able to support all subjects in all universities. All this is further evidence of a tightening grip by CNRS of the distribution of its money in the university system and of an increasing emphasis on its own laboratories. But the picture is not all black for university researchers supported by CNRS. Papon insists that the total value of support will not fall — it will just be distributed differently.

In the past, CNRS guidelines for university support have centred on "excellence". Exactly what the research was about was not of great concern. Now, excellence will be necessary but not sufficient, says Papon; "coherence" with CNRS policy will also be expected. This year, for example, those policies include a regional dimension — a wish to improve support in the north and west, relatively undeveloped scientifically; an emphasis on interdisciplinary research, the barriers between disciplines being felt to be particularly strong in France; and special support for life sciences.

Clearly, this marks an increase in "directive" rather than "responsive" support for science, a matter of debate in many other countries. But France is to go still further. CNRS is to sign — possibly this week — an outline agreement with the "Direction de la Recherche", which with MEN is responsible for the universities. This will mark a new degree of cooperation between the two bodies. Some will fear this development as a device for extending CNRS policy now coloured strongly by its exposure in the ministry of industry and research, and by the aim of the present government of achieving economic growth through science and technology — into university research.

Both MEN and CNRS insist, however, that there will be room for independent policies. There is, however, considerable unease in the universities about the way in which CNRS support and influence will develop, particularly among those who do not see their work as of particular economic relevance. And it has been exacerbated by the removal of "individual aids" — a system whereby CNRS supported individuals with two or three technicians, as a step to becoming an "associated laboratory" of CNRS shared between university and the centre. There are not enough technicians to go round, says CNRS. So such early support is to be limited to a few selected "young groups", while individuals will apply for "free contracts" — two-year grants without technicians that are not designed to lead to associated status.

Robert Walgate

Concerted selectivity

IN its unusual declaration, the French cabinet has offered its support to CNRS in pursuing a policy of "selectivity and concentration", which echoes the policy of a certain Science and Engineering Research Council across the Channel. In outline, the declaration announces that CNRS will increase cooperation with "all involved in research", including:

- **The universities, with which CNRS will sign individual and collective agreements. The declaration foresees "decisions, which will allow the creation of new associations [joint research groups, the principal form of CNRS support] or the closure of others, taken in liaison with the universities and the minister of education, and taking into account the quality of the research, its relevance to national scientific priorities and the balance between regions".**
- **Other research councils. The declaration singles out INRIA (informatics), CNET (telecommunications), and CNEXO (ocean science).**
- **Industry, where the declaration foresees more collaboration agreements between CNRS and industry.**
- **"Social partners", a neologism for trade unions, involving increased research on the impact of new technologies.**
- **And the regions ("states"), which will see more conventions lasting several years such as those signed with Nord-Pas-de-Calais and Provence-Côte d'Azur, relating CNRS policy to local needs perceived by the (political) regional councils.**

The declaration also states that "voluntary mobility of researchers will be encouraged". And this could indeed be an important step for CNRS, for it would allow, for example, a CNRS scientist to leave his or her post for up to 3 years to work in industry, freeing that person's salary and position for the period. This could dramatically increase the fluidity of CNRS laboratories. Robert Walgate

Unesco

US scientists hit by withdrawal

Washington

THE United States' decision to withdraw from the United Nations Educational, Scientific and Cultural Organization (Unesco) by the end of this year has dismayed many US scientists who have worked closely with the agency. They say that Unesco's scientific programmes have generally remained free from the political posturing that has tainted the agency's other activities, and warn that withdrawal may exclude US scientists from valuable international data-sharing agreements.

Formal notice of the decision was delivered to Unesco at the end of December. Under United Nations regulations, the withdrawal will not take effect until 31 December 1984, and the United States will therefore continue to pay its $50 million contribution (about a quarter of Unesco's budget) for the remainder of this year. Explaining the American decision to pull out, a State Department spokesman said Unesco had politized virtually every activity it conducted, mismanaged its budget and routinely adopted policies hostile to the institutions of a free society.

Both the National Academy of Sciences and the National Science Foundation (NSF) told the State Department at the end of last year that a decision to pull out could have damaging repercussions for US science. A letter from the academy characterized science as one of Unesco's success stories and pointed out that no alternative machinery existed to service international collaboration concerned with such subjects as the oceans, climate, the solid Earth and the biosphere.

NSF has made a detailed study of Unesco's scientific value for the State Department but its findings have not yet been published. The general view of scientists with knowledge of Unesco, however, is that the benefits of staying in outweigh those of leaving:

- Dr Della Laura, chief of international hydrology at the US Geological Survey, says Unesco's International Hydrology Programme has an excellent record and has successfully steered clear of political issues. If US scientists are unable to continue their participation, she says, the United States will "greatly miss" an arena in which global information of hydrological problems is rapidly exchanged.
- Unesco's activities in the Earth sciences have received similar praise from Dr Lin Hoover, deputy chief of international scientific programmes at the Geological Survey. About 300 American geologists a year take part in research under the Unesco-sponsored International Geological Correlation Programme and their exclusion will force the United States to negotiate countless bilateral agreements

0028-0836/84/020098-01$01.00

© 1984 Macmillan Journals Ltd

and will reduce opportunities for US geologists to visit foreign sites in the company of international experts.

Dr Roger Revelle, professor of science and public policy at the University of California, San Diego, says the United States has been deeply involved in Unesco's Intergovernmental Oceanographic Commission and two major projects it is helping to coordinate — Tropical Oceans and Global Atmosphere (TOGA) and the World Ocean Circulation Experiment (WOCE). He says the intergovernmental machinery established by Unesco is essential to gain permission to set up tide gauges and other equipment in territorial waters.

The State Department has hinted during informal conversations with the scientific community that some of the money now given to Unesco could be diverted to the apolitical and, some believe, more efficient International Council of Scientific Unions (ICSU). But the suggestion has been dismissed by the National Academy of Sciences, which insists that only a governmental-level organization can command the prestige and resources necessary to coordinate global research programmes.

The academy is not, however, wholly uncritical of Unesco. Its letter to the State Department acknowledges that its management of scientific programmes could be improved. Now that the United States has announced its firm intention to leave, US scientists who work with Unesco hope that they will nevertheless be allowed to participate in individual programmes of obvious benefit to the United States. The United States intends, for example, to remain within the copyright convention and the International Programme for the Development of Communication. The State Department has left the door open, but it remains to be seen whether Unesco itself, jilted by its biggest paymaster, will agree.

Peter David

Solar energy

Sahara's power for Europe?

Rehovot

A SCHEME that may one day permit Sahara sunshine to power the factories of Europe was discussed this week by participants in an International Workshop at the Weizmann Institute of Science in Rehovot and at Ein Bokek on the shores of the Dead Sea.

The idea is to collect solar energy in a desert area (say Israel's Negev, the south-western part of the United States or the Sahara) and to transform it into energy-rich chemicals for piping to industrial areas further to the north where, in yet another catalytic transformation, this energy would be released as heat for use in manufacturing processes.

Professor Israel Dostrovsky of the Weizmann Institute, organizer of the workshop, points out that "solar heat has generally been used close to the site where it is collected. This is because transforming it into electricity and then back to heat (if that is what the customer needs) entails a loss of about 75 per cent of the energy." He hopes, however, that the "thermochemical pipeline" will make it possible to deliver solar heat to a remote customer with much smaller losses and, simultaneously, provide a convenient way to store solar energy for night-time use.

Participating in the workshop were US and West German scientists who have studied the transformation of surplus nuclear energy into chemical energy with much the same goals in mind. Indeed, the Germans have even built a successful 10-megawatt pilot plant at Jülich, near Cologne. But solar energy presents an additional challenge because, unlike nuclear energy, it does not come in a steady flow.

A one-megawatt pilot plant to test the "thermochemical pipeline" concept will be built on the Weizmann campus with energy from a solar tower.

While institute researchers have no delusions about solar sources supplying most of the world's energy needs, they think the new scheme is worthy of support — and particularly from the oil sheikhs of Saudia Arabia and the Gulf States. "If we're successful", Professor Dostrovsky observes, "their vast stretches of sunbaked sand will still be profitable after their oil wells run dry."

Another original Israeli development in the solar sphere won international recognition two weeks ago when a contract was signed between the Edison Company in Southern California and Ormat Turbines of Yavne, south of Tel Aviv. The Israeli firm will be responsible for the construction and operation of a solar-pond power plant, expected to supply 12,000 kilowatts of power to California Edison customers by the end of 1985, and 48,000 kilowatts in 1987 (with the addition of three more ponds).

Ormat operates two solar ponds at the Dead Sea; the first, inaugurated in 1979, produces 150 kilowatts, and the second, opened last year, produces 5 megawatts. They exploit the fact that in a standing pond of salt water a salinity gradient is created, one which they have learned to maintain artificially. Temperatures at the very salty bottom reach up to 90°C, not very hot compared with the 500°C steam used in conventional turbines but hot enough to drive the special Ormat turbine generators in which fluid with a low boiling point is substituted for steam.

Here, as elsewhere, scientists and politicians now speak frequently about what they expect to be happening by the year 2000. By then, Professor Dostrovsky hopes that his "solar pipeline" will be contributing significantly to a solution of energy problems, and the Israeli Ministry of Energy predicts that 11 per cent of the country's total energy needs will be met from solar sources, divided in the following way: 12 per cent from "passive" energy (direct absorption not using collectors), 30 per cent from flat-plate collectors, 30 per cent from concentrating collectors producing industrial process heat, 16 per cent from photovoltaic systems producing electricity directly, and 12 per cent from solar ponds.

In another 16 years, it will be possible to know whether this extremely optimistic prediction proves to be correct.

Nechemia Meyers

A place in the Sun

THE multitude of solar energy projects in Israel, were reviewed in a report recently presented to the Food and Agricultural Organization of the United Nations by Israel's Agricultural Research Organization. The authors, D. Groves and I. Segal, point out that more than 700,000 Israeli households now have their water heated by solar energy, thus accounting for 65 per cent of all domestic water heating. The result they say, is a saving of 6 per cent in electricity generation and 2 per cent in all primary energy supply. "These figures", they add, "make Israel the world's largest *per capita* solar energy user."

Almost all this water is heated by flat-plate collectors, developed in the 1950s by Dr Harry Tabor and now manufactured by no fewer than 130 individual companies.

Some of Israel's most interesting solar energy work is being done at the Desert Research Institute of Ben-Gurion University of the Negev in Sdeh Boker, the isolated place at which solar enthusiast Ben-Gurion made his home after retiring from the premiership. At Sdeh Boker, one finds, for example, a special adobe house — constructed by Michael Kaplan and Eli Levin-Epshtein — which requires only US$12 for total winter heating as against an average of $1,000 for neighbouring homes.

Solar energy is also of interest to Israeli farmers. It is, for example, being used for heating greenhouses from which vegetables and flowers are exported to Europe during the winter months. All systems under development take advantage of the fact that even though Israeli winter nights tend to be cold, there is usually excess heat available for collection during the day. Several researchers call for the collection of this heat in water, which can be recirculated during the evening hours, while others favour its collection in special salt hydrates, which are placed inside double-layered pastic sheets from which the roofs and walls are constructed. The salts change from liquid to solid and back at about 20°C, at the same time releasing large amounts of heat.

Indian science congress

Pursuit of quality endorsed

Mesra, Bihar

STRINGENT control of higher degrees and special schools for highly gifted children were among the recommendations of the 71st Indian National Science Congress, which met at the Birla Institute of Technology in Mesra last week.

The congress, which resembles a cross between the British Association and a political rally has, since 1976, had a "keynote theme", on which it presents recommendations to the relevant government bodies, and on which it receives an implementation report in the following session. This year's theme was "Quality science in India — ends and means".

This slogan was interpreted in different ways, Professor M.G.K. Menon made an impassioned plea on the serendipity value of basic research. The Prime Minister, Mrs Indira Gandhi, who opened the congress, argued that, since "quality of science" presupposed "quality of life", it implied a joint campaign of scientists against the threat of nuclear war and the subsequent ecological disaster. By the second day, however, the keynote theme had crystallized into how to overcome the prevailing mediocrity of Indian science.

India, as a number of speakers noted, can claim the world's third largest "scientific work-force" in the sense of employed persons with at least a first degree in science. In establishing this human resource, which is vital for the development of Indian agriculture and industry, there has been a concentration on quantity rather than quality of graduates. Furthermore, the low remuneration of young research fellows (around 600 rupees — £40 — a month, or about half the salary of a young graduate entering business or the civil service) means an inevitable wastage on financial grounds. The congress president, Professor R.P. Bambah of Punjab University, maintained that unless research fellows immediately have their stipends doubled, there is no long-term hope for Indian science.

This utopian suggestion did not find its way into the draft "recommendations" which this year seem aimed as much at the scientific community itself as at the government. On the subject of pay, the "recommendations" firmly reject the new scheme of promotion of lecturers to readers and readers to professors on the basis of length of service. This scheme has recently been introduced, under trade union pressure, at a few leading universities, including Delhi, in place of the existing system of promotion by merit as and when a vacancy occurs. The new system, many argued, is a blueprint for apathy and complacency.

One practical suggestion for improving scientific "quality" was that the titles and abstracts of PhD theses should be published together with the names of the adjudicators awarding the degree. This is intended to counteract the frequently reported slackness and even downright dishonesty in the degree process. At the same time, criteria for higher degrees should be standardized because several universities have acquired a reputation for "easy" PhDs. Government agencies which award research fellowships should establish a joint selection examination, and awards should be made on the basis of merit only — ending the present "positive discrimination" in favour of the disadvantaged. The civil service requirement that certain posts must be filled by graduates should be revoked, thereby reducing the pressure on the universities.

In general, Indian education was felt to be too examination-oriented — and Professor Bambah's suggestion of "pace-setting" schools for the highly gifted was based on the concept that such young people could better develop their potential in a peer group in which they would learn to work together as a team.

The congress itself had a competitive aspect — competitive awards to young postgraduate scientists selected by the Indian National Academy of Sciences and by the congress. Ironically, the first award announced was for work on RNA. Yet, although it recently hosted a major genetics conference and in spite of the importance of the subject for agriculture, India has been able to establish virtually no university departments of genetics — apparently because of a preponderance of classical botanists and zoologists in the upper echelons of the life sciences.

Vera Rich

Educational computing

Academics gain from competition

Pasadena, California

COMPETITION in the computer industry is nothing new, but computer companies are now competing for an unusual prize — the privilege of giving away millions of dollars of equipment to universities. In recent months the California Institute of Technology (Caltech) has received computers worth some $1.4 million from Hewlett-Packard and Data General at a 75 per cent discount, Massachusetts Institute of Technology (MIT) has closed a deal with IBM and Digital Equipment Corporation (DEC) under which those companies will donate $50 million in equipment and support over five years and IBM has announced a programme of grants to 20 universities totalling $50 million in hardware for the support of manufacturing engineering education. Many other companies are also offering large numbers of small computers to universities at much reduced cost.

The companies' motives are varied. Those offering bulk deals on work-stations may well be hoping to lock in a future market in personal and business computers. The Caltech and MIT deals, however, appear to reflect the companies' need to tap a body of expertise that they themselves lack, particularly in developing educational software and in assembling large integrated computer networks. Charitable donations to universities also yield tax benefits to the companies that substantially reduce their net cost. Educational software will probably be the most tangible benefit to the companies. MIT has agreed to offer IBM and DEC non-exclusive licences for any software developed with their equipment.

The present dearth of serious educational software is universally bemoaned. "The state of the art in educational uses of computers is a disaster", says Steven Lerman, an MIT engineering professor who directs the programme there. Most educational software is little more than electronic workbooks, which is "the biggest waste of hardware, software, and people's time ever invented". Lerman foresees the use of computers in a variety of truly novel ways that will take advantage of their unique capabilities. "Dry laboratory" experiments could demonstrate chemical titration, thermodynamic principles and the like with the help of sophisticated graphics — and without wasting valuable laboratory time and space.

MIT is itself raising $20 million for the programme. IBM and DEC, besides donating the machines, are providing software and maintenance support and are lending MIT several full-time personnel.

Here at Caltech, the emphasis is also on educational software development. The university is placing three of the four VAX-class Data General machines it has acquired in the hands of undergraduate students. Eventually, these machines are expected to become the central computers in a network that will include multiple work-stations. Geoffrey Fox, a theoretical physicist who was recently named Caltech's first dean for educational computing, believes it is a mistake, however, to have one computer to each student. Fox says that to get students to use computers and to stimulate the much needed software development requires a diversity of machines with capabilities beyond the "lowest common denominator" that inevitably determines the selection of a personal computer that will be issued to every student. Fox points to one US university that acquired an IBM personal computer for every freshman, only to find that the average computer was used for one hour per day for games and for one hour as a terminal for the university's main computer.

Greenhouse effect

Energy efficiency may help

Washington

ALTHOUGH a global warming due to a build-up of atmospheric carbon dioxide is inevitable, it can be postponed significantly by improved energy efficiency, according to a new study prepared for the National Science Foundation*. The report, by engineers at Massachusetts Institute of Technology (MIT) and Stanford University, breaks with recent studies by the Environmental Protection Agency (EPA) and the National Academy of Sciences (NAS) in suggesting that practical and effective steps can be taken at once to soften the blow of a warming induced by carbon dioxide. By drawing out to several centuries the time it will take for the atmospheric carbon dioxide concentration to double, society will buy time to develop new energy technologies and to enable agriculture and population distributions to adjust to climatic shifts.

The study found that "realistic energy strategies" based on improvements in energy efficiency could hold the atmospheric carbon dioxide concentration to 420 p.p.m. by the year 2050, up from 340 p.p.m. at present. Based on the recent experience of the United States and other industrialized countries, the report concludes that energy use per real dollar of gross national product can be expected to fall by 1 per cent per year.

"It makes sense to develop strategies for reducing fossil fuel carbon emissions, rather than relying solely on research to narrow uncertainties and/or ameliorative measures such as building dikes and developing new strains of 'greenhouse-resistant' crops", the report says. EPA last year suggested that there was little point in trying to halt the carbon dioxide build-up; the NAS report suggested that uncertainties in model predictions (which point to an average global warming of a few degrees centigrade for a doubling of atmospheric carbon dioxide) preclude any immediate steps to halt the build-up.

The NSF study, however, noted that increased energy efficiency, apart from being the only practical route to slowing the build-up of carbon dioxide, is economically attractive in its own right.

The NSF report found that solar and renewable energy technologies are not likely to displace fossil fuels to a sufficient extent to make a significant difference in carbon dioxide emissions in the short run. Nuclear fission, because it will probably be considerably cheaper than coal (especially if acid rain prompts new emission controls on sulphur), is seen as the only energy technology besides improved efficiency with a major short-term effect on atmospheric carbon dioxide.

The study discounted strategies to extract carbon dioxide from fossil fuel combustion and sequester it, for example, in deep ocean waters. This is only one of several half serious ideas for technical fixes lately advanced. One scheme would add sulphuric acid to the atmosphere — an "artificial volcano" that would cool the Earth, offsetting the carbon dioxide-induced warming — but the price is estimated to be $50,000 million per year. Another would establish mirrors in Earth orbit to increase sunlight available to high-latitude ocean waters; the increased light would permit the ocean biota to utilize the nutrient excess in these waters, increasing biological uptake of carbon. The capital cost for this venture is estimated very roughly at $100,000 million.

Stephen Budiansky

**Global Energy Futures and CO_2-Induced Climate Change* (by D. Rose, M. Miller & C. Agnew) MIT Energy Laboratory Report No. 83-015, prepared for the Division of Policy Research and Analysis, NSF.

Acid rain

Uncertainty persists in Europe

A REPORT on acid deposition in Britain prepared by the Warren Spring Laboratory for the UK Department of the Environment highlights the need for a long-term programme of measurement on acid precipitation. Asked to examine the distribution in Britain and time trends of acidity in precipitation in Britain and northern Europe, the authors were able to consider only a part of Britain's land surface for lack of measurement stations between which comparisons could be made.

The report therefore calls for a commitment to long-term support for measurement, especially at high altitudes and in urban areas. More use should be made of wet-only collectors (which are not susceptible to contamination by gases and particulate matter) and frequent comparisons between institutions should be made to eliminate differences due to measurement protocols.

The authors, under the chairmanship of C. F. Barrett of the Warren Spring Laboratory, were unable to reach firm conclusions about recent trends in deposited sulphate, chiefly because of climatic variations from year to year, although nitrate concentrations do appear to have increased since 1957. Looking back further, to the beginning of the century, however, there is evidence that wet depositions of both sulphate and nitrate have increased in approximate agreement with emissions.

From the few sites at which daily analyses are made, the frequency distribution of deposition of acidity seems highly episodic, with typically 30 per cent of annual acidity being deposited in 5 or 6 days. Although acidity cannot be uniquely apportioned between anions, statistical correlations suggest that at most sites studied, sulphuric acid is responsible for about 70 per cent of acidity and nitric acid for 30 per cent. The largest predicted depositions of hydrogen ions occur in Cumbria and parts of Scotland, where levels are of the same order as parts of Scandinavia and North America. Dry deposition of sulphur, however, is a more local phenomenon related to local sources of sulphur dioxide.

Meanwhile, the European Economic community's Council of Ministers has been unable to reach agreement on a proposal from the Commission of limiting air pollution from industrial plant. The proposal, which is largely procedural, ran aground over an article on emission standards which entailed the eventual possible use of community-wide emission standards, to be introduced by a two-thirds majority. The Commission was prepared to drop the offending article, but the Netherlands objected: Britain and Ireland, in contrast, could not accept the use of such standards in any circumstances. A second much more specific Commission proposal on limiting air pollution from combustion plants, which would have important consequences for power stations, specifies targets for reductions in emissions from both old and new plant, but leaves the options open to governments on how it should be implemented. This proposal has not yet been formally discussed by the council, but is likely to generate an unusual amount of heat.

Tim Beardsley

Scientific correspondence

Careful readers will have noted that correspondence is now published under two headings — the familiar general correspondence (see pages 103 and 104) and "Scientific Correspondence" (see pages 115 and 116). The objective is to provide a means by which readers can raise points of a rather technical character which are not provoked by articles or letters previously published (where "Matters Arising" remains appropriate).

Contributions to Scientific Correspondence will not usually be formally refereed. □

UK research councils

Astronomers' future undecided

CONTROVERSIAL recommendations are expected from the Manpower and Site Review Panel of the UK Science and Engineering Research Council (SERC), whose proposals have now been sent to SERC's Astronomy Space and Radio (ASR) board for discussion at its meeting later this month. The panel was instructed to find ways of saving more than £1.5 million from the ASR board's budget for the next financial year (1984–85). Whether this has been done by recommending radical changes or by piecemeal cuts, the board will face some painful decisions.

The panel, under the chairmanship of Professor A.P. Willmore, was asked to review the need for each of three establishments — the Rutherford Appleton Laboratory, the Royal Greenwich Observatory (RGO) and the Royal Observatory in Edinburgh (ROE) — taking into account the fact that much of the United Kingdom's gound-based astronomy will in future be carried out by remote control at facilities in Hawaii (Mauna Kea) in the Canaries (La Palma).

The terms of reference were given considerable sting by the added injunction that the ASR board must save £1.5 million or so. (The board spent about £6.5 million in grants in 1982–83.) RGO had already taken a battering last year in a review of SERC's institutions by a cost-cutting unit of the British Government under Sir Derek Rayner. That report, hotly disputed by RGO staff, recommended that Herstmonceux Castle — a major part of the RGO site — should be sold off (see *Nature* **304**, 5; 1983) and that a merger of RGO and ROE should be considered.

When the Willmore panel was set up, it was widely thought by the UK astronomical community that SERC was indeed intending to merge RGO and ROE. The matter is variously seen as a battle between satellite and ground-based astronomers over the distribution of funds, between SERC's head office and its institutions, or between SERC establishments and universities. Still others fear that the geophysical research supported by the ASR board (mainly concerned with the upper atmosphere and the magnetosphere) will be sacrificed to preserve major astronomical projects such as the millimetre-wave telescope on Mauna Kea and ROSAT, an X-ray satellite supported mainly by West Germany but with UK participation.

Not surprisingly, SERC is keeping its cards close to its chest. Indeed, the proceedings of the Willmore panel have been so secret that its members have not been allowed to remove documents from SERC's offices. The committee's members hold strong and divergent views and it is unlikely that they will make a unanimous radical recommendation. But whatever the panel has decided, the ASR board may choose to ignore it, or instruct the panel to think again.

Philip Campbell

Biotechnology

Gamma interferon race begins

Boston, Massachusetts

GENENTECH has won the race to begin US clinical trials of gamma interferon synthesized in recombinant bacteria. The trials of the drug produced by the California biotechnology company began last month under the direction of a pioneer in clinical interferon research, Dr Jordan Gutterman, a haematologist at the M.D. Anderson Hospital and Tumor Institute in Houston, Texas, one of the largest cancer centres in the United States.

Several biotechnology and pharmaceutical companies have a big stake in the success of gamma interferon, which they hope will be an anticancer drug. The competition is fierce and close: Biogen has been carrying out clinical trials of gamma interferon in Europe and Japan since September 1983. As well as demonstrating gamma interferon's antiviral action, preclinical trials by several companies have demonstrated significant antitumour activity, and greater stimulation of the immune system than by other interferons. So gamma interferon could make a good partner for other immunosuppressive chemotherapy drugs.

Gutterman has been treating patients with natural alpha interferon for the past six years, and began trials with cloned alpha interferon three years ago. He and his co-workers reported last week in the *New England Journal of Medicine* (**310**, 15; 1984) that each of seven patients suffering from hairy cell leukaemia — a slow-growing B cell neoplasm for which there is no consistently effective treatment — were brought into complete or partial remission by injections of natural alpha interferon; Gutterman's group has recently begun extending these experiments with cloned alpha.

The Texans are looking forward to rapid progress with their tests of gamma interferon; their experience over the past year with the scarce and expensive natural product is expected to help them rapidly to determine the best way to administer the drug — an important point, because intramuscular injections of natural gamma interferon have been found to be cleared rapidly from the body. Gutterman's group has laboriously had to determine the proper procedure for administering the drug by a prolonged intravenous infusion.

Gutterman is very excited about the possibility that gamma interferon may potentiate the effects of alpha. Despite his success with hairy cell leukaemia, he has found that only a quarter of the patients with melanoma or breast cancer respond to alpha interferon treatment. Substantial *in vitro* and *in vivo* data using mouse and human interferons have shown synergistic antiviral and antitumour effects, and Gutterman hopes that human malignancies may respond similarly. Combined trials may begin in a year or so, once the pharmacology of gamma interferon is worked out.

Chile under Pinochet

SIR — I have read (*Nature* **306**, 11–12; 1983) that Chilean universities have not only survived Pinochet's dictatorship but, due to a mixture of despotic benevolence, the existence of a United Nations Regional Program for Post-Graduate Training and the quality of young scientists nurtured by their seniors, Chilean science has in fact been revived. The article exudes an aura of optimism for the future, ending with a reflective statement about the necessity for pragmatic objectives and the dismissal of "over-ambitious utopian dreams and violence".

I read the article with dismay. Certainly, history has taught me that tyrants have at times been generous patrons of the arts and conspicuous builders, but my naive heart would like to believe that tyranny kills all it touches. Furthermore, the article is disturbing because its anecdotal account of hardship fals short of picturing the excesses of Pinochet's murderous tyranny, and because the reported relaxation of the regime is hard to reconcile with reports from Amnesty International of repression, torture and assassination still rampant after 10 years of dictatorship. "Between 1973 and 1979, hundreds . . . disappeared after being arrested by the security forces . . . coordinated by the Direccion de Inteligencia National (DINA). Disappearances and killings . . . remain officially unexplained. Since 1977, a number of alleged members of banned political parties and organizations . . . have died in the custody of the CNI (Central National de Informaciones, Chile's secret police), in circumstances which indicate that they may have died after torture or . . . [been] killed by other means." (*Political Killings by Governments, An Amnesty International Report*, 20–21; 1983).

Let us put the survival issue into perspective. By the time the medical school community was taken to the soccer field, the university had already paid a grievous price — the disappearance of faculty members who were underground, exiled, or already dead. Later on, economic constraints brought the "ousting of many people and early retirements". The survivors were those silenced by fear and various collaborators — those people with deep-rooted rightist convictions and those pragmatic enough to accommodate their principles to the establishment. On the one hand, there was repression and on the other, compliance and consensus. How much consent is hard to evaluate, but guidelines for suppression and removal of academic personnel to be effective after the coup were clearly spelled out in a document signed by a pediatrics professor of the University of Chile.

The subject of the "open and constructive discussion" in Chilean universities which are more open and constructive than those that occur "in other countries respected for their democratic governments" is not spelled out. I must then conclude that despotism has consented not to be too despotic for people to discuss — allow me to guess — the sodium pump, quantum statistics, the cost of paper clips, promotions and fund allocations. I strongly believe in academic freedom but the liberty that we are told Chilean scientists enjoy occurs simultaneously with hardship upon the Chileans that cannot be silenced nor should it be forgotten. It consists of 50 per cent unemployment in the shanty towns, it consists of the hunger of the poor, desperate citizens fighting with stones against police tear gas and bullets, people still being tortured and in prison; it consists of exiled people, it consists of the dead.

I hope that Chilean transition to democracy will occur soon and that it will be obtained without further violence. However, as long as the aims of a few are placed above the elemental rights of the enslaved many, the germ of violence will be there. The preservation of an ivory tower for a score of people cannot be the constraint to justice and equality. Justice and equality must not be utopian dreams.

Creation or evolution

SIR — In the article "Creation versus evolution: no middle way" (*Nature* **305**, 571–574; 1983) George M. Marsden presents an interesting historical review of the roots of the creationism/evolution controversy in the United States, but slights its most important aspect: the science education issue. Because of pressure from antievolutionists, the amount of evolution covered in pre-college science books is documentably declining, or, even worse, is being accompanied by "theories" that the world was produced in six 24-hour days about 10,000 years ago.

There is value in Marsden's reminder that scientific creationism is more than a scientific issue. Proponents are genuinely worried that civilization and the moral order are threatened by modern antisupernaturalism. Because they define creationism narrowly, as Marsden documents, they see evolution as creationism's antithesis. Opposition to evolution thus becomes a moral charge. Textbook censors like the Gablers in Texas discourage discussions of the philosophic implications of various world views because they lead to "relativism", "humanism" and other nasty ideas. They therefore demand that creationism be presented in *science*, not history, social studies or philosophy classes. Unfortunately, there is no scientific evidence for (and much against) ideas such as obligate carnivores being former vegetarians (in order to have lived compatibly on Noah's Ark).

Whether or not evolution is "a key mythological element in a philosophy that functions as a virtual religion" (antisupernaturalism) is beside the point. Indeed, evolution *can* be the basis of a philosophical world view, but conceivably so can heliocentrism, or even photosynthesis. Evolution, heliocentrism and photosynthesis can be presented without philosophical trappings — it is difficult to imagine the latter two being taught otherwise. The facts are that photosynthesis occurs, the Sun is the centre of the Solar System, and change through time (evolution) has occurred. Children need and deserve to be taught this. One can be aware of the role of history and culture in science and still insist that science be taught in the science classroom.

Research Corporation

SIR — Research Corporation takes exception to the article published in *Nature* on 13 October, 1983 (p.569) which alleges mistakes in the handling of a non-isotopic method for detecting gene sequences invented by David Ward of Yale University. That Yale did not "bungle" the technology transfer process is demonstrated by that institution's successful programme of licensing it to industry for development and commercial use.

Research Corporation, a nonprofit foundation that evaluates, patents and licenses inventions for a number of colleges and universities, was erroneously identified as having performed a review of Dr Ward's discovery. In fact, Yale did not submit the invention to Research Corporation, and this organization did not evaluate it or offer any opinion as to its worth.

As a further comment, and in contradiction to writer Budiansky's assertions, Yale University continues to maintain an invention administration agreement with Research Corporation, which now bases the larger part of its Invention Administration Program in Tucson, Arizona (not New York).

JOHN P. SCHAEFER

Research Corporation, 6840 East Broadway Boulevard, Tucson, Arizona 85710, USA

● We apologize for the error. Contrary to what was implied by Yale officials, Research Corporation did not see the original invention. Dr Schaefer is also correct in saying that an arrangement between Yale and Research Corporation continues; it is, however, non-exclusive, and Yale expects largely to assume these functions itself with the establishment of its own office — Editor, *Nature*.

Paying for high-energy physics

SIR — Your article "Paying for high-energy physics" (*Nature* 1 December 1983, p.421) gives numerous false impressions.

The argument that it was not really necessary to observe the $W^{\pm}$ and Z° bosons, because "the [Salam–Weinberg] theory [of weak interactions] . . . may . . . have been held to have been confirmed by what was learned (at CERN) in the 1970s about neutral currents" is wrong. The neutral current data, in common with all earlier information about weak interactions, are consistent with a force of zero range. It is true that those data are also consistent with the Glashow–Weinberg–Salam (GWS) theory, in which the weak interaction is due to the exchange of the W and Z bosons, thereby having finite range $\hbar/m_Z c \sim 2 \times 10^{-16}$ cm. However, the existence of such bosons was only a speculation until they were discovered at CERN earlier this year. The theoretical arguments for the existence of some structure in weak interactions at short distances were rather compelling but the GWS theory was not unique in fitting the earlier data. There were rival theories of the same type with additional bosons, and also very different theories which predicted W and Z bosons but as composite rather than fundamental objects.

The fact that the masses of the W and Z agree with the GWS predictions, within the errors, is certainly not sufficient to establish their true nature. Indeed, the experiments have reported some tentative evidence for the decay $Z^0 \rightarrow e^+ e^- \gamma$, which cannot be explained by the GWS model. If confirmed, this radiative Z^0 decay might perhaps be accommodated by models in which the W and Z are composite. In any case, these anomalous events may indicate quite new physics to come. The fact that the GWS model is still potentially so vulnerable shows that we are still at the beginning of this chapter of the story.

Next, the 2,500 university physicists who use CERN facilities each year go there because it is their deep wish to be involved. There would be many more if there were funds to support them. It must also be remembered that this subject holds a very deep fascination both for the general public and especially for the young scientist still at school, as becomes very clear from interviewing for university entrance. What is going on at CERN is one of the most exhilarating enterprises mankind has known, a great flight of the creative human spirit to determine in full detail what a strange world we live in, and it is not surprising that so many physicists wish so profoundly to take part in this demanding work. You ask what they would be doing if CERN were not there: the answer is simply — "something less significant and much less interesting".

The insinuation that the advanced techniques used at CERN are just borrowed from American laboratories is simply false. The proposal to transform the existing CERN Super Proton Synchrotron into the Proton-Antiproton Collider, with which the W and Z were produced, provides the most obvious counter-example. The crucial technique of stochastic cooling of the antiproton bunches — the breakthrough which made this step to much higher energies possible — was proposed and developed at CERN: it has now been taken up by the Americans for their Tevatron collider under construction at Fermilab, near Chicago. CERN also proposed and built the first proton–proton collider (ISR). Furthermore, CERN is notable for its development of new experimental methods; the neutrino horn, multiwire proportional drift chambers, the development and use of large liquid argon and/or uranium calorimeters, the ring-imaging Cerenkov detector and the ISIS detector (a trend-setter in the problem field of particle identification at high energies) were all pioneered at CERN, to mention just a few outstanding items. Under the pressure of experimental needs, substantial technical developments have been made at CERN which have proved beneficial outside in fields as diverse as electronics and shipbuilding. It would be healthy for this country if more UK engineers were to gain practical experience by taking part in the advanced engineering work going on at CERN all the time.

We agree that the time may be ripe for intercontinental collaboration in the 1990s. For the present, the Americans feel they may be able to build a superconducting collider on their own. However, we cannot anticipate *any* time when experiments will be unnecessary; "cheap theory" alone will not be able to account with certainty for the microscopic structure of the world in which we live, without the aid of experiment.

C. H. LLEWELLYN SMITH
Department of Theoretical Physics,
University of Oxford,
Oxford OX1 3NP, UK

SIR — The "News and Views" item "Paying for high-energy physics" (*Nature* 1 December 1983, p.421) contains so many inaccuracies that it is difficult to know how to reply adequately at reasonable length, but perhaps I may attempt to correct some of its more misleading assertions.

Comparing the SF 680 million CERN annual budget with the materials cost of the new electron–positron collider, LEP, is not comparing like with like. The annual budget is divided almost equally between staff costs — and many of the staff are engaged in building LEP at present — and materials costs. The materials budget this year is being spent on running five accelerators (one of which operates in two very different modes), and in building LEP. Electricity consumption is appreciable, but not outrageous for a large scientific laboratory whose facilities operate round the clock, seven days per week for much of the year. Indeed, it has been estimated recently that stopping all of CERN's accelerators for a complete year would save a total of just SF 25 million in electricity charges — 3.7 per cent of the annual budget.

The super proton synchrotron will not be closed when LEP is completed. It is required as an injector for LEP and, more importantly, is expected to be used in the LEP era by up to half of the European high energy physics community for both fixed target and colliding beam experiments.

It is both scientifically unsound and unnecessarily churlish to attempt to run down CERN's recent triumphs in detecting the W and Z bosons. Maintaining that the observation of neutral currents by CERN a decade ago was a sufficient test of weak interaction theory is as sensible as claiming that the Venus de Milo may be adequately appreciated by studying the shadows cast on the floor by the spotlights that illuminate it. Continuing the analogy, the recent experiments have provided us with a clear silhouette, in remarkable agreement with the descriptions furnished by those distinguished intellectual tourists, Glashow, Salam and Weinberg. We are almost persuaded that they have been telling us the whole truth, but LEP should provide the detailed colour photographs that will settle the issue beyond doubt.

The article poses the question of what CERN's 2,500 visiting scientists would be doing if CERN did not exist. The most plausible answer is: "Working around the world in groups too small to be effective, lacking contact with their peers and the stimulation of direct competition, performing second-rate research with inadequate facilities". No thanks — Anon

SIR — Here is a formal "You're welcome" to all those authors who have recently included in the Acknowledgements section of their published papers a line thanking me, an Anonymous Reviewer, for critical comments on their manuscript. I suggest, however, a moratorium on this practice, since thanking me in print is a not particularly informative use of expensive journal space. If authors really feel that they must show their appreciation for an exceptionally helpful anonymous review, they can send me a personal note of thanks via journal editors. Then at least I'll know that it was my comments, and not those of some other Anonymous Reviewer, that were so appreciated. *Name withheld by request*

● *Nature*'s policy is not to thank Anonymous Reviewers — when the misdeed is spotted.

Antarctic mining regime at risk

John Maddox

In Washington next week Antarctic Treaty members will wrestle with mineral exploitation. Their task would be easier if territorial claims were subsumed in a wider framework.

LAST week, it was announced from New Delhi that an Indian expedition of 83 people had reached the coast of Antarctica in a chartered Finnish ice-breaker. Next week, in Washington, there will be a special meeting of the Antarctic Treaty powers to resume the drafting of a convention on the exploitation of mineral resources in Antarctica. The two events are strictly independent, but in the minds of delegates gathering in Washington, there will seem to be an important connection. For the accession of India to the Antarctic Treaty last September (together with Brazil) seems to have reminded the parties to the treaty that change is close at hand.

Anxiety about the future of the treaty has been mounting for several years, and certainly since the Law of the Sea Conference reached its abortive conclusion in 1982. The principle that the sea-bed should be regarded as the "common heritage of mankind" was rejected by several governments, that of the United States chief among them, so that the status of the resulting treaty is in doubt. But the earnest advocacy of the doctrine of common heritage by the governments of many developing countries, and its obvious applicability to the Antarctic, has inevitably cast doubt upon the durability of the arrangement under which the Antarctic Treaty vests responsibility for the management of a whole continent in the governments that agreed to give themselves that responsibility at the end of 1959.

In its essentials, the difficulty springs not from the Law of the Sea but from the reasons why the negotiation of that treaty was frustrated—the general unwillingness of newly formed governments to fall in with international arrangements previously agreed. Uppishness of this kind has become a familiar irritant of established governments, in the United Nations and in other international gatherings. But if the Law of the Sea were less like a dead letter, it would present the Antarctic powers with a further and more particular difficulty, for the sea-bed provisions of the Law of the Sea Treaty defined as the common heritage of mankind even those parts of the oceanic sea-bed lying south of 60°S, the region in which the Antarctic Treaty applies.

Mercifully, this potential conflict between the two treaty regimes remains an academic matter. So, superficially, the Antarctic Treaty itself may seem to be. What can be the value of an international treaty to regulate the uses made of a tract of territory whose practical value is, for the time being, only marginal? That is too detached a view. The benefits of the Antarctic Treaty far transcend its immediate utility. First, the treaty how nations may be persuaded to bury conflicting interests in the pursuit of a more general common interest, for that reason, is a valuable precedent for further international agreements on more urgent matters, arms control for example. Second, the treaty does serve to regulate matters of great importance to one section of the international community, for it has assured access to Antarctica for those wishing to make scientific observations in the region. Third, and more recently, the treaty has provided a framework within which it has been possible to arrange for the orderly exploitation of marine resources. The ambition among the treaty powers to conclude a similar agreement on mineral resources is natural enough, and laudable as well, but more contentious.

To the scientific community, the origins of the treaty are also important because the treaty is a tangible legacy of the International Geophysical Year (IGY), the eighteen-month-long period of coordinated geophysical observation from 1 July 1957 to 31 December 1958. Antarctic exploitation was inevitably a conspicuous part of that cross between a planned research programme and a public relations campaign. In the climate of the late 1950s, with the cold war dragging to its end, the notion that the only substantial part of the Earth's solid surface free from weapons of any kind should be permanently demilitarized won ready consent.

In reality, there was little choice. Open access to the Antarctic by scientific expeditions during IGY had been agreed by the states with territorial claims on Antarctica but the declaration by the United States and the Soviet Union that they would continue with Antarctic research after IGY put the claimants in a fix, as did the continuing disputes among those with overlapping claims.

All with an interest in the Antarctic discovered a common interest in postponing a resolution of these difficulties, and a common fear that if they failed to agree among themselves, matters would be taken out of their hands. The result is that the negotiation of the Antarctic Treaty, on the initiative of the United States, was accomplished in just over eighteen months.

The treaty itself is a simple document. It declares that "in the interests of all mankind", Antarctica shall "continue forever to be used exclusively for peaceful purposes" and that international cooperation and "freedom of scientific investigation in Antarctica" typified by experience during IGY should also continue. Its provisions forbid the establishment of military bases in Antarctica, the testing of weapons (including nuclear weapons) and even the disposal of radioactive waste. Access to all parts of Antarctica is assured, but the twelve original parties to the treaty are free to inspect activities undertaken by other governments — a right exercised almost exclusively by the United States. Nothing is said about the duration of the agreement except that after thirty years from ratification (completed on 23 June 1961), full parties should be free to ask for a conference to review the operation of the treaty and, by implication, to consider its future.

The twelve founder members were a motley crew. They included the two superpowers of the 1950s, Khruschev's Soviet Union and Eisenhower's United States, a group of European states with traditional interests in Antarctic exploration (Belgium, France, Norway and the United Kingdom), Japan, and a group of states in the Southern Hemisphere including three former British dominions (Australia, New Zealand and South Africa) and Argentina and Chile, neighbours in South America and rivals in Antarctica.

Both the United States and the Soviet Union have eschewed claims of sovereignty in Antarctica. Britain and its former dominions consider, however, that they have legitimate claims on parts of the continent, as do Argentina and Chile. The Norwegian claim (predating Amundsen's trans-Antarctic journey) seems not to be a live issue, but Britain, Argentina and Chile claim sectors of Antarctica which overlap with each of the other two. It is not clear whether France has made a valid claim to sovereignty or has merely reserved the right to do so, but the issue has been put firmly in abeyance by the Antarctic Treaty, under which claimants and non-claimants agree that claims to sovereignty will be neither advanced nor liquidated.

But if the moratorium on the issue of Antarctic sovereignty has not made that contentious issue go away. For one thing, the treaty partly owes its existence to the fear, in the late 1950s, that disputes about

© 1984 Macmillan Journals Ltd

Antarctic sovereignty might get out of hand. Second, the structure of the treaty guarantees continuing precedence for the original signatories.

This is the central issue on which the discontents of other governments have focused. Briefly, the treaty distinguishes between three groups of adherents — the twelve original signatories which are automatically consultative parties, signatories which have qualified as consultative parties by their demonstration of "substantial scientific research activity" in Antarctica and other signatories which have not thus qualified. West Germany and Poland became consultative parties in 1979 and Brazil and India (rather hurriedly) last September. Ordinary signatories of the treaty, which now include the People's Republic of China, number more than a dozen. East Germany, Romania and Uruguay formally accompanied their adherence with a protest at the discriminatory provisions of the treaty. Malaysia, not a signatory of the treaty, has gone further by raising the issue of Antarctica at last year's general assembly of the United Nations.

In the circumstances, the charge that the Antarctic Treaty is a club of self-interested governments cannot easily be resisted. This, after all, is what the treaty implies. The charge that the treaty powers are an exclusive club is, however, unfair. The fact that India was able to qualify last year as a consultative party on the basis of expeditions to Antarctica in two successive summers is a sign that, in the present international climate at least, the consultative parties are not concerned like robins to keep others out. Indeed, the consultative parties have now taken to saying that complainants against the alleged exclusiveness of the treaty have a simple remedy — sign the treaty, mount a couple of expeditions to Antarctica and then become full members. This does not, however, satisfy those who insist that they have no obligation to abide by rules in whose development they played no part.

The broader challenge to the treaty, from states such as Malaysia, based on the doctrine of common heritage and the argument that all members of the United Nations should participate in the administration of Antarctica, will be resisted by many of the consultative parties on more pragmatic grounds. Antarctica, they will insist, has been well managed since 1961, and is likely to be badly managed under a different regime.

On the question of management, the consultative parties are on sure ground. Since 1961, access to Antarctica by scientific expeditions has indeed been open. From the outset, oversight of exploration and of the treaty's requirement that the results of scientific investigations should be freely exchanged has been the responsibility of the Scientific Committee on Antarctic Research (SCAR), a committee established by the International Council of Scientific Unions which predates the Antarctic Treaty itself. This arrangement, whereby a group of governments has turned over to a non-governmental body such an important scientific advisory function, may well be unique.

SCAR has played an important part in the principal developments within the framework of the treaty since it first entered into force, culminating in the Canberra Convention for the Conservation of Antarctic Marine Resources, which was signed in 1978 and which entered into force in 1980. This had been preceded by two other measures concerned with the conservation of Antarctic flora and fauna (promulgated in 1964) and Antarctic seals, signed in 1972 and ratified six years later.

Like the Antarctic Treaty itself, these measures seek to reconcile conflicting interests by verbal ingenuity. Thus the convention on marine resources does not include the word "exploitation" but "rational use" is implicitly defined as a part of conservation. The result is that the convention on marine resources may be understood as a fisheries convention by those who wish to hunt for krill (chiefly Japan and the Soviet Union). Exploitation is not yet on such a scale as to call in question the restrictions that may in due course be recommended. Meanwhile, SCAR (and its companion committee SCOR, where "O" means oceans) is mounting a detailed investigation of the ecological balance between krill and marine animals in Antarctica.

The exploitation of mineral resources is bound to be more contentious because it touches directly on the issue of sovereignty. The need for an agreement of some kind has been a recurrent theme at consultative meetings since the 1970s. The meeting next week in Washington will be seeking to build on what has been agreed so far — that the need for an understanding is urgent not so much for economic reasons (for nobody suggests that mining anything would be practicable in the near future) but to defend the Antarctic Treaty regime against its critics and that the fragile Antarctic environment must at all costs be safeguarded. Paradoxically, even the non-claimant members of the treaty acknowledge that one of the best defences against the argument that Antarctica should be thrown open to allcomers is that some of them have claims to sovereignty.

The crucial question to be decided is the mechanism by which the exploration and exploitation of Antarctic minerals should be licensed. The consultative parties seem to have agreed that there must be an "external accommodation" in the sense that outsiders should be free to participate provided that they demonstrate practical activity, not merely academic interest, in the discovery of minerals and agree to abide by the rules.

The complementary "internal" accommodation, intended to reconcile the interests of claimants and non-claimants, is causing more trouble. The intention at present seems to be that there should be some central body with responsibility for mineral exploitation in Antarctica as a whole together with a number of sub-authorities The hope seems to be that claimant governments would continue to regard involvement with the management of Antarctic resources, perhaps with special responsibility in areas on which their claims have been lodged, as a sufficient recompense for not flying their national flags too ostentatiously.

Legally, there is an important precedent for such an arrangement — the treaty signed in the 1920s under which Spitsbergen (Svalbard), east of Greenland, was acknowledged to be the sovereign territory of Norway, which required that Spitsbergen be demilitarized and which provided for the exploitation of mineral resources (chiefly coal) by other parties. Poland and the Soviet Union pay a modest royalty on what they mine to cover the cost of administration.

Politically, were it not for the overlapping claims of Argentina, Chile and the United Kingdom, the transfer of such a system to Antarctica would be relatively straightforward. Non-claimants could join with the claimants in the detailed administration of sectors of Antarctica, thus satisfying the *amour propre* of all parties and postponing the issue of sovereignty. The snag is that the three overlapping claimants are in no mood to settle on a basis for joint administration of any part of Antarctica — Argentina and Chile cannot agree even about the disputed part of Tierra del Fuego, Argentina and Britain have the Falklands war behind them.

This is why the circumstances call for a new departure. The Antarctic Treaty powers are right to calculate that an external accommodation will not be possible while they cannot agree among themselves on how to regulate their affairs in Antarctica. Against the background of the past three decades of successful co-operation in Antarctica, and with the knowledge that however vast may be the resources hidden beneath the ice-covered continent, the economic value of Antarctic minerals will always be marginal, there is a need for a face-saving form of words.

The ideal would be that the claimants should abandon their claims, but that is too much to ask. A second best is that the claimants should agree that, for some specified period (say a century), their territories should be committed to the trusteeship of others — the twelve original signatories of the Antarctic Treaty for example. That, after all, is the reality of what has been happening since 1961. It would be infuriating if the rewards of two decades of constructive work should now be put in hazard because the claimants, none of which could hope to exercise its sovereignty, cannot swallow such a meagre mouthful of pride. □

From Santorini to Armageddon

North American tree-ring data confirm that volcanic eruptions can cause climatic change. So would nuclear war, but to a degree not yet calculable.

THE general concern with cataclysmic happenings on the surface of the Earth requires no special explanation. In a more or less orderly world, people are naturally disquieted by the notion that their lives may be disrupted (or even ended) by events over which they have no control. For if the collision of the Earth with an asteroid at the end of the Cretaceous may have extinguished the dinosaurs and many other kinds of species, may not less spectacular but more probable events abruptly change the course of history without warning, breaking the comfortable expectation of continuity with the future that we now enjoy?

That, no doubt, is part of the reason why there is such widespread alarm about the risk of nuclear war. The same applies to the more recent general preoccupation with the results of purported recalculations of the long-term consequences of a nuclear war, those for example represented by the summary of a calculation now published by Professor Carl Sagan and a group of associates (*Science* **222**, 1283; 1983). They assert that after a nuclear war, the Earth's atmosphere would be so laden with dust that solar insolation of the surface would be drastically reduced, thus also reducing surface temperatures and perhaps even reducing the rate of photosynthesis to below that required for survival.

The issue is not as academic as it might be made to seem by the remark "We'll all be too dead to care". That might be true of the populations of the principal combatants and their neighbours, but populations in the other hemisphere, while damaged by fall-out, would still have a vital interest in the feasibility of survival. So if there are long-term climatic consequences of nuclear war, it is important to know what they are. Those wishing to follow the argument might prudently begin not with the article by Sagan *et al.* but with that of Lamarche and Hirschboek from the University of Arizona in this issue of *Nature* (page 121).

That rich tale, fascinating in its own right, also has a bearing on the question raised by Sagan *et al.* What Lamarche and Hirschboek have done is to correlate with the known occurrences of major volcanoes the occurrences of frost damage rings in bristlecone pines, the long-lived species by means of which dendrochronology in eastern California has been extended back for nearly 5,500 years. The results are striking. Frost-rings in bristlecone pines do indeed correlate well in time with the occurrence of major volcanoes, among which Krakatoa (1883) is, so to speak, the type-specimen.

Within the past century, during which historical records approach in accuracy the tree-ring calendar, the data show that frost-rings follow eruptions more frequently than if the two kinds of events were independent. But during this period, there were summer cold snaps in the western United States not attributable to eruptions (1941 and 1886 for example) and, in the earlier period, many major eruptions that appear not to have caused frost damage.

That is what would be expected. The veil of dust from a volcanic eruption is only one of many causes of climatic variation, while eruptions differ markedly in character, some yielding only short-lived dust clouds.

Several features of the study now described are nevertheless especially pleasing. First, the notion that major eruptions can cause detectable climatic events is modestly confirmed. Second, the work further supports the view that one of the meteorological consequences of volcanic dust in the atmosphere is (in the Northern Hemisphere) an expansion of the circumpolar vortex in the mid-troposphere and a tendency for the pattern of the stratospheric jet-stream to consist of a more exaggerated sequence of lunges towards low latitudes. That should enhance the confidence of model-builders and support those who have been suggesting that the cold spring and autumn in the Rocky Mountains last year (1983) may indeed have been a consequence of the El Chicón eruption in 1982. Finally, a valuable bonus, there is an objective date (1626 BC) for the volcanic explosion of virtually all of the island of Santorini (then called Thera), one of the traumatic events of late Minoan history.

The bearing of this careful study on the question raised by Sagan *et al.* is only indirect. It does, however, qualitatively confirm one of the chief predictions of the consequences of nuclear war — that dust in the atmosphere can have long-term climatic consequencs. But many of the events suggested by the tree-ring study seem to have been exceedingly short-lived. Thus the frost-rings found in California, Utah and Nevada in 1884, the year after the eruption at Krakatoa, seem to correspond with a southerly incursion of cold air from Canada on 9 and 10 September (after a summer that had admittedly been unusually cool).

By contrast, Sagan *et al.* predict much lowered temperatures — on some pictures of the course of a nuclear war, perhaps 20 per cent below normal for 3–6 months afterwards. The chief reason for this huge discrepancy between the consequences of a nuclear war and a volcanic eruption stems from the assumptions made about the quantities of dust carried into the stratosphere by the different events. But everybody, Sagan *et al.* included, agrees that this field is shot through with uncertainty.

The assumptions made about nuclear dust appear, however, to be chiefly responsible for the differences between the new and earlier calculations, that of the 1975 report from the National Academy of Sciences for example. In what is called the "baseline scenario" of a nuclear war (10,000 nuclear explosions with a total yield of 5,000 megatonnes), it is supposed that 1,000 million tonnes of dust would be created, that 80 per cent of that would find its way into the stratosphere and that 8.6 per cent of that would consist of particles smaller than 1 micrometre radius. These assumptions would load the atmosphere with more fine dust than previous calculations have assumed. The new assumptions (and the use made of the one-dimensional model for predicting the attenuation of the obscuring effects of stratospheric dust) are, unfortunately, to be discussed only in a paper still "in preparation". Until that appears, those familiar with the well documented difficulties of measuring the composition and the size distribution of dust even from well studied volcanoes such as Mount St Helens (see for example Brazier, S. *et al. Nature* **301**, 115; 1983) will be wondering where the apparently much more precise data about nuclear dust has come from.

None of this implies that such calculations should wait on accurate parameters for all possible variables. It would probably also be common ground between the authors of the latest calculation and their more quizzical readers that the use of one-dimensional models is likely to yield upper limits for the effects calculated. What might, however, reasonably be asked of the authors is that their conclusions, derived as they are from necessarily crude models and uncertain data, should be plainly stamped with the label QUALITATIVE for fear that their apparent precision may prove spurious.

Genetic engineering

Prospects for transforming monocot crop plants

from Richard Flavell and Raymond Mathias

THE past year has at long last seen the successful genetic modification of plants by the insertion of DNA from the test tube — although as yet only tobacco and a few closely related species have been transformed with new active genes[1-4]. Success has come by exploiting the components of the natural DNA transfer system of the soil bacterium *Agrobacterium tumefaciens*, a pathogen of many dicotyledonous species (dicots). During the infection process, the bacterium transfers a part of one of its plasmids, the Ti plasmid, into the host plant chromosomes[5]. What the genetic engineers have done is to place new genes into an appropriate segment of this plasmid, using a combination of *in vitro* recombinant DNA techniques and *in vivo* bacterial genetics. When the bacterium carrying the engineered plasmid is used to infect plant cells, the plasmid segment carrying the new genes is transferred into the plant chromosomes.

The excitement that has rightly accompanied these successes has been tempered by the knowledge that the natural host range of *A. tumefaciens* is restricted only to dicots. So an efficient technique for DNA transfer cannot be used to transform monocotyledonous species (monocots). Yet the genetic transformation of monocots remains a most important goal in plant genetic engineering, for many of the world's major food crops are monocots — rice, barley, maize, wheat and sorghum, for example. The many claims that 'transformed' monocot plants have been obtained after the microinjection or uptake of DNA into immature or mature seeds[6-8] have been based on the observation of altered plant phenotypes, but have not been supported by the more definite proofs that can be gained using molecular biology. Much effort is now being directed towards giving such proof.

The successful transformation of tobacco involves the incorporation of DNA into single cells, the selection and culture of transformed cell lines and the regeneration of whole plants therefrom. Few plant species can, however, be taken from single cells through the tissue culture steps as readily as can tobacco and the important monocot crop species have proved particularly recalcitrant in this respect[9]. But while a reproducible single-cell system capable of efficient regeneration into whole plants may still be some way away for the important monocot species, recent developments suggest that excessive pessimism is unwarranted.

In maize, for example, certain cell culture lines produce protoplasts which readily regenerate to the callus stage[10,11], while other lines can be maintained as cell suspension cultures in which aggregates of 20–50 cells can be regenerated to callus and plants with high efficiency[12]. Protoplasts from embryogenic cell suspension cultures of pearl millet have been reported to undergo sustained divisions that give rise to calli, embryoids and whole plants[13]. Also protoplasts of barley, rice, sorghum and diploid wheat have been proliferated to the callus stage but without plant formation[14]. These developments do not necessarily imply that it will soon be possible to insert DNA into single monocot cells and to regenerate transformed plants efficiently from them, but it may be now worthwhile attempting the microinjection of DNA into the separate cells of a cell cluster capable of regenerating into a transformed plant.

As the regeneration of whole plants from single cells is likely to remain a severe problem for many monocots, other routes for plant transformation are now being explored. These approaches seek to avoid the problems of cell culture altogether by making the gametes the recipients of introduced DNA. The pollen of many species can be germinated *in vitro*[15] and the sperm nucleus can be made a target for the microinjection of DNA as it passes down the pollen tube. If the injected genes are maintained in the nucleus after transfer of the germinated pollen to an ovary, they may be incorporated into the zygote nucleus by the natural fertilization process, resulting in a transformed embryo and potentially a transformed plant. In those species in which the pollen remains viable for only a short period or in which pollen germination *in vitro* is not yet possible, microinjection directly into the egg cell is being explored as an alternative. The principal difficulty in this approach is that the egg is buried in the maternal ovary tissue and is difficult to locate but may be less serious in those few species whose fertilized ovules can be cultured and microinjected after excision.

Little is as yet known, in plants, of the influence of the structure of the potentially transforming DNA which, in principle, can influence the survival of the DNA, the efficiency with which it is integrated into a host replicon and whether it behaves as a replicon. It may be that any piece of DNA introduced into a nucleus has a high probability of being incorporated into a chromosome, as found in mammalian cells[16]. The dramatic progress in transforming *Drosophila* by the microinjection of P-elements into suitable recipient genotypes is a striking illustration of the value of using vectors with special properties[17-19]. Complete P-elements encode genes which facilitate their autonomous integration into the chromosomes of *Drosophila* lines not carrying specific repressors of P-element activity. Novel genes spliced into these elements disrupt the essential 'mobility' gene functions, but when such 'inactive' engineered elements are microinjected into *Drosophila* embryos along with unmodified P-elements, the 'trans' acting gene products of the unmodified elements facilitate the chromosomal integration of the engineered element with their new genes.

Transposable elements were first recognized in maize[20], and new examples have now been isolated from maize chromosomes by DNA cloning techniques[21-23] (see, for example, this issue, page 127). These elements are therefore for use in experiments analogous to those which have been so successful for the incorporation of genes into *Drosophila*. The segment of plasmid DNA that is transferred to dicotyledonous chromosomes by *Agrobacterium* is a type of transposable element. Many laboratories are therefore beginning experiments to see if its transposition can be induced in monocot cells when the Ti plasmid is introduced into cells by means other than natural infection by *Agrobacterium*.

The recognition of transformed cells, tissues or plants, is of critical importance in transformation studies, for successful events may occur only at low frequencies. Consideration must therefore be given to the availability of selectable marker genes for incorporation into vectors. Suitably engineered antibiotic resistance genes from prokaryotes have already been used successfully to select transformants from the *Agrobacterium* transformation system and these genes[1-4], with their proven efficiency, will no doubt be incorporated into monocot vectors. An interesting selection scheme has been developed for transforming cell lines lacking functional alcohol dehydrogenase (ADH) genes: the vector genes will carry a functional ADH gene[23], putative transformants will be cultured under anaerobic conditions where selection operates in favour of cells containing ADH[24] and the presence of functional ADH detected easily by a simple staining reaction[25].

Taken together, these developments have clearly demonstrated the feasibility of plant transformation in dicots. The progress in monocot cell culture and the expanding interest in the development of alternative methods of DNA delivery, coupled with the availability of Ti-plasmid, monocot transposable elements and selectable markers, suggest that the transformation of at least some monocot species cannot be far off. The need to combine the

0028-0836/84/020108-01$01.00

right techniques with the right recipient cells and a suitable DNA delivery system may still keep us waiting a little while longer. We must remember too, that for agriculture, the ability efficiently to insert genes into one monocot crop species is not enough. We must learn how to manipulate all the major crop species. □

Genetics

The origins of men with two X chromosomes

from Paul Burgoyne

APPROXIMATELY one in 20,000 men have a female (XX) sex-chromosome constitution. The occurrence of XX males is of great interest because it raises the question of whether testes can develop in the absence of the testis-determining locus located on the Y chromosome. Recent work has done much to support the view that XX males have a testis-determining fragment of the Y chromosome attached to one X chromosome, but a group of three related XX men do not fit this explanation. As is often the case, these exceptions are potentially the most informative.

In 1966 Ferguson-Smith[1] suggested that the paternally derived X of XX males may harbour a testis-determining fragment of the Y. He envisaged that the fragment might have been transferred to the X by 'accidental crossing-over' between the X and the Y in the father and referred to the event as an X–Y interchange. Originally the idea of X–Y interchange was founded on the observation that some XX men fail to inherit their father's allele for the X-linked red cell antigen Xg^a. The interchange model explains this by assuming that the *Xg* locus, which is located at the tip of the short arm of the X chromosome, is lost from the paternal X when it acquires part of the Y short arm containing the testis-determining locus.

In 1979 another dimension was added to the X–Y interchange model when Evans *et al.*[2] showed a difference in length between the short arms of the two X chromosomes of some but (as others have emphasized[3]) not all XX men. This was taken as evidence for the addition of Y-chromosomal material to the short arm of the paternal X, and in terms of the interchange model this implied that the accidental crossing-over could be unequal with more Y-chromosomal material being gained than X-chromosomal material lost. Polani[4] considers that the organization of the X and Y pairing segments may predispose them to unequal exchanges.

Two recent reports provide further genetic evidence of X–Y interchange. The first[5] indicates that the steroid sulphatase locus (*STS*), which, like *Xg*, is near the tip of the X short arm and escapes X-inactivation, can likewise be missing from the paternal X in some XX males. While most XX men have high levels of STS activity befitting their XX status, in the case described not only was STS activity low but one of the Xs failed to express STS when incorporated in a human–mouse somatic cell hybrid line. The second report[6], published in this issue of *Nature*, describes an XX male who failed to inherit his father's *Xg* allele but did inherit his father's Y-linked 12E7 ('*Yg*')[7] allele. This is the first genetic demonstration of both the loss and gain of material by the paternally derived X of an XX male.

In view of the weight of evidence for X–Y interchange in the aetiology of XX maleness, it was reassuring to hear a report by Bishop, Fellous and Weisenbach at a recent meeting in Oxford that by using Y-specific probes[8] they have identified Y-specific sequences in the DNA from all three XX males they have examined (and see this issue of *Nature*)[9].

The case for X–Y interchange thus seems to be proven, but is this the whole story? Albert de la Chapelle[3] has long argued for a heterogeneous aetiology for XX males, and when the extremely rare familial cases are considered there is certainly food for thought. Let us consider two pedigrees; that described by Kasdan and colleagues[10] where there is an autosomal dominant pattern of inheritance, and that of de la Chapelle[3] in which transmission through females formally rules out dominance. The autosomal dominant pedigree has a direct counterpart in the XX sex-reversal mutation *Sxr* in the mouse. Although inherited in autosomal fashion *Sxr* has turned out to be a fragment of the Y which is regularly transferred to the X during meiosis in carrier males[11,12]. This intriguing finding was discussed in an earlier article[13]. The important point in the present context is that an apparently autosomal pattern of inheritance can be produced if crossing-over is obligatory in the pairing segment of the X and Y[14]. Thus the Kasdan pedigree may, like *Sxr*, be explained by X–Y interchange.

The de la Chapelle pedigree cannot be dismissed so easily. First, the recessive inheritance in my view argues strongly against the involvement of the Y-borne testis-determining locus. More important, in one of the three XX males in this pedigree both X chromosomes appear to be maternal, since he does not express the paternal alleles for *Xg* (located at the tip of the X short arm) or *Xm* (located near the end of the X long arm). I believe this unlikely anomaly of X inheritance suggests that this XX male has received from his mother two X chromosomes bearing a recessive 'testis-determining' mutant. Wolf[15] has put forward a model for testis determination in which testis differentiation is prevented in XX individuals by an X-borne repressor locus. When a Y chromosome is present this repressor locus is in some way neutralized so allowing testes to develop. This model allows for the development of testes in XX individuals if both copies of the X-borne repressor locus are inoperative through mutation or deletion. Such an X-borne recessive effect is consistent with the de la Chapelle pedigree, provided that the X-borne repressor locus is inherited in a pseudoautosomal fashion (like *Sxr*). I have previously suggested pseudoautosomal inheritance of this repressor locus in order to explain recessive XX sex reversal in goats[14].

The XX males from these two pedigrees are a must for investigation using Y-specific probes. The XX males from the Kasdan pedigree may well reveal Y-chromosomal sequences, but I for one shall be very surprised if this is also true of de la Chapelle's XX males. □

Applied mathematics

Scattering by fractal objects

from Eric Jakeman

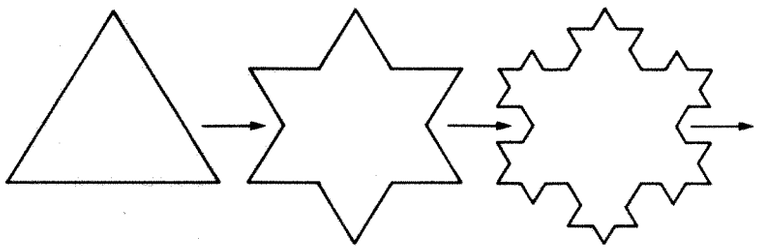
"A FRACTAL is a mathematical set or object whose form is extremely irregular and/or fragmented at all scales." So runs Mandelbrot's definition of the term he coined in an essay first published[1] in French in 1975. He points out that classical mathematics has on the whole been concerned with Euclidean geometry based on the notion of smooth shapes and with the continuous evolving dynamics of Newton, whereas most natural phenomena, objects and patterns are abruptly changing, with structure on many scales. Thus the mathematical description of a whole range of familiar objects ranging from coastlines to trees presents great difficulties. In his essay, Mendelbrot shows how these can be resolved by the concepts of fractal geometry[2].

To reduce the totality of fragmented objects to a class requiring minimal parameterization, it is necessary to introduce the notion of 'scaling', which refers to the similarity in appearance of an object when it is subject to arbitrary magnification. Regular scaling fractals can be generated by following simple iterative construction procedures. The best known object of this kind is the Von-Koch 'snowflake' curve[3] obtained by repeatedly replacing the middle third of each element of the construct by two vertices of the appropriate equilateral triangle (Fig. 1). This leads to an object of finite area but infinite perimeter. Its bounding curve is evidently continuous but does not have a locally well-defined direction (slope or derivative).

Although a number of these strange but regular geometrical constructs are known, the vast majority of natural objects are fragmented in an irregular way and it is in the description of these randomly varying structures that the concepts of fractal geometry are proving most valuable. An early investigation of one such structure is attributed to L.F. Richardson, who found that the length of land frontiers and coastlines appears to increase as the resolution of the measurement improves[2]. Thus, if the length of the coastline of Britain is determined using a 100-km measuring stick, the answer will be smaller than that obtained using a 10-km stick, which will resolve and therefore have to negotiate the longer distance round smaller scale structures such as river estuaries and inlets.

This observation leads quite naturally to the principle parameter characterizing a scaling fractal curve, for it is found that if the length of the measuring stick is l then the apparent length of such a curve is proportional to l^{1-D}, where D is a number greater than unity, but not necessarily integral, which uniquely characterizes the scaling behaviour of the curve. The value of D is in fact a measure of the density with which the curve fills the space (surface, volume) in which it is embedded and can be interpreted as an anomalous or fractal dimension.

Although Mandelbrot's ideas have diffused rapidly, the most striking applications of his work remain the numerical simulations of random fractal objects such as islands and landscapes which, in spite of being entirely artificially contrived, acquire an uncannily familiar appearance when supplemented by suitable shadowing effects[2]. The ability to recognize the familiar in this context is dependent, of course, on information being carried to the eye by light scattered from the object and there is indeed increasing interest in the properties not only of light but of other frequencies of the electromagnetic spectrum as well as of sound waves which have been scattered by fractal objects.



In fact there is a long history of interest in one multi-scale scattering system — the turbulent medium. Although not referred to as such, a fractal description involving the Kolmogorov spectrum has commonly been employed since the pioneering work of Tatarski in the early 1960s[4]. The full implications of using models of this type have only become clear recently, however, through the quantitative investigation of scattering by simple models of fractal surfaces[5]. Since the slope of a fractal surface is ill-defined, ray or geometrical optics do not apply and the scattering is of an entirely diffractive nature. This results in relatively low contrast intensity (brightness) patterns[6] that are very different from those generated by smoothly varying surfaces whose lens-like behaviour produces bright geometrical features of the kind which can often be seen on the floor of a swimming pool.

In the case of pulsed scattering, the fractal dimension of the surface is represented in the temporal decay of the tail of the return pulse, so that this kind of surface should in principle be easily recognizable and capable of characterization by remote sensing techniques[7]. In practice variations of reflectivity may confuse such measurements, while real surfaces will also have smallest (inner) and largest (outer) scale sizes with a hierarchical or fractal structure in between. To investigate the latter regime, the wavelength of the probing radiation has to be much greater than the height fluctuations over inner-scale sized elements of the surface (so that their scattering effect can be neglected by comparison with that of the larger scales) and the receiving optics must be designed to collect radiation from an area of the surface which is smaller than the outer scale size.

Although many solid surfaces of both microscopic and geophysical proportions appear to be fractal[8], at least over some limited range of scale sizes, there is evidence that certain fluid systems are better described as objects with fractal slope. The sea surface is one such system, for example. Ray or geometrical optics effects do play an important role in determining the characteristics of the scattered intensity pattern in this case, leading to strong variations in brightness. Since the local surface curvature remains ill-defined, however, lens-like behaviour does not occur and a new kind of geometrical optics or short-wave limit is found which is free from the catastrophes (caustics, focusing points) associated with smoothly varying surfaces. The statistical properties of the scattered intensity remain finite in this limit and can again be related to the fractal dimension[9].

The full implications of current work on fractal scattering cannot yet be properly assessed but will surely extend beyond the immediate practical objectives of the investigations. Certainly many new and sometimes surprising results are emerging by recognizing the role of fractals in well-established areas of science as well as in the more exotic frontier areas such as dynamical systems and chaos. □

Galaxy structure

Two kinds of halo gas identified

from Joel Bregman

ALTHOUGH most of the cool gas in our galaxy lies in the galactic disk, it is not entirely confined there and the study of gas above and below the disk (halo gas) has been an especially vigorous area of research during the past few years. Unfortunately, it has frequently been difficult to discriminate between disk and halo gas, for it is not possible to determine distances to gas clouds and we can only look at the halo gas through the disk. In a recent paper C. E. Albert has used a new approach[1], a study of low ionization gas within 8,000 light years of the disk (the lower galactic halo). She has conclusively shown that a considerable amount of neutral (cool) gas exists in the lower galactic halo and that there are two kinematically distinct types of halo gas.

Gas is believed to exist in the halo in several different forms[2]. Weak radio continuum emission has been attributed to synchrotron emission from cosmic ray electrons that may extend up to 30,000 light years from the disk[3,4]. Plasma at temperatures of millions of degrees may also permeate the halo and be responsible for part of the diffuse X-ray background (0.1–2 keV)[5]. Virtually nothing is known about the vertical distribution of this gas except that it is unlikely to extend beyond 30,000 light years from the disk. Radio telescope surveys have revealed the presence of neutral hydrogen gas at a few hundred degrees kelvin but with unusual velocities[6,7]; this gas is presumed to lie in the halo as well. Finally, absorption line spectroscopy in the optical and ultraviolet bands has been used to demonstrate the presence of halo gas with a temperature in the range 10^3–10^5 K[8–10].

Optical and ultraviolet spectroscopy have been powerful tools for analysing the properties of halo gas. By detecting absorption lines caused by gas intervening between the Sun and a background source (a star or quasar), one is able to estimate the column density, vertical distribution, chemical abundance and temperature of the gas. Strong absorption is commonly detected for the ultraviolet resonance lines of C IV and Si IV, which is interpreted as evidence for warm gas (10^4–10^5 K) lying between 1,500 and 10,000 light years above the disk[9–11]. For neutral gas (< 10^3 K), a more precise study of the vertical distribution has been made by comparing the total column density (from the 21 cm HI emission line) with the column density between the Sun and a halo star (using the Ly α line of neutral hydrogen)[12].

There is a vast amount of gas above the thin disk of the galaxy (half-thickness about 300 light-years) and about one-third of the total column density of neutral gas is beyond a height of 3,000 light years. However, little neutral gas exists further than 6,000 light years from the disk. Albert has added to our understanding by comparing the difference in absorption for pairs of stars, one of which is just above the galactic disk and the other in the halo. She shows that the halo is rich in gas and distinguishes between two types of neutral halo gas: a layer of gas similar to disk gas that has a scale height of about 3,000 light years, and higher velocity gas richer in certain heavy elements (Ti, Ca, and Na) that is found only above the disk. Whether or not there is a true difference between the distribution of warm and neutral gas and how these components are related to the million degree gas and the cosmic rays remains to be seen.

The absorption-line gas is rotating, but not precisely with the galactic disk. This has been clearly shown by Albert and others[13] who demonstrated that the velocities at which absorption against halo stars is observed are considerably different from these expected for corotating gas. Evidently, these gas clouds have large peculiar velocities with respect to a corotating halo. The data are qualitatively consistent with features of a corona that rotates more slowly than the disk and of galactic fountain models. More data are needed before the various models can be tested critically and more studies along the lines of Albert's would be valuable. □

Palaeontology

Small companions for early dinosaurs

from Michael Benton

FOSSILIZED cave systems around Bristol, England, have yielded an important fauna of small reptiles dating from the times of the early dinosaurs, about 200 million years ago. Until recently, these were thought to be specialized upland faunas because the animals were rather different from those of the typical lowland dinosaur beds. Strong evidence has now, however, been presented against this view, and new information on the dating and palaeoecology of these remarkable faunas has also been given[1–6].

Fossil mammal teeth were first found in the Bristol fissures by Charles Moore over 100 years ago[7], and the first reptile remains were described[8] in 1939. These consist of the bones of a small lizard-like animal (*Clevosaurus*), very like the unique living tuatara, *Sphenodon,* from New Zealand. Many more important mammal and reptile fossils have been collected since then from dozens of fossil caves in South Wales and around Bristol. The reptiles include a remarkable small gliding animal called *Kuehneosaurus,* isolated bones of the carnivorous crocodile-shaped *Rileya* and the dinosaur *Thecodontosaurus,* a crocodile, and various as yet undescribed sphenodontids and small archosaurs (crocodiles/dinosaurs/thecodontians). The latest new forms to be described have been *Gephyrosaurus*[5,6], a 40-cm long lizard-like animal, and *Planocephalosaurus,* a small sphenodontid[3].

The dating of the fissures has always been a problem. Some may be late Triassic (Norian) in age, others Rhaetic, and others early Jurassic (between about 190 and 225 million years ago). Some of the South Wales fissures have been dated as Rhaetic or early Jurassic on the basis of plants, spores and gastropods[9]. One of the fissures near Bristol has yielded more abundant spores which suggest a Rhaetic age[1]. The main fissure sites, and the reptiles that they have produced are described in references 1, 4, 9–11.

At the end of the Triassic period, the scenery around Bristol consisted of limestone hills in which deep fissures and caves formed. The climate was subtropical with wet and dry seasons, and the vertebrate fauna consisted of dinosaurs, small lizard-shaped reptiles and early mammals. Occasionally, these animals fell into the fissures, or were washed in by flash floods with mud and sand. The habitat was assumed to have been a rocky 'upland',

Michael Benton is in the University Museum, Parkes Road, Oxford, OX1 3PW.

well away from the lush pastured dinosaur country below. However, there is now strong evidence for marine influence in at least one fissure (Tytherington); marine microfossils (acritarchs and dinoflagellates) occur, kerogen derived from marine algae is abundant[1] and a glauconitic clay mineral has been found which could indicate brackish conditions[2]. This fissure at least must have been located near the coast with its base below sea-level. This would permit mixing of the meteoric waters that washed the debris into the cave with saline waters from the sea.

We must now view the fissure animals as representing a sample of a lowland fauna rather than a peculiar upland fauna. Very large animals are excluded — like the five-metre long dinosaur *Plateosaurus* which is found widely in Europe at the same time. However, many single bones of its smaller relative *Thecodontosaurus* have been found in various fissures. The most abundant animals, however, are lizard-sized, from 10–50 cm in total body length. A detailed study of the ecology of an assemblage of these small animals from Slickstones Quarry has just been published[4], and it gives us a unique impression of the fauna scuttling around beneath the shadow of the dinosaurs.

The Slickstones fauna consists of 12 or more forms, and includes abundant remains of six different sphenodontids. Most of these probably ate insects and other invertebrates, as does the living *Sphenodon*, but one form at least may have been herbivorous — a conclusion suggested by patterns of tooth wear. The authors go on to suggest that differences in the composition of the 'faunas' found in different fissures were caused by interspecific competition for food resources[4]. This seems to be stretching the evidence a little far, unless we assume that the beasts actually lived in the caves. The sphenodontids were preyed upon by dinosaurs and other archosaurs which are represented in the fissure fossils by a variety of jaws and isolated sharp knife-like teeth.

The Bristol fissures should produce a great deal more important information. Many of the fissure reptiles have yet to be described and the careful collecting techniques being used should also yield much new information on their palaeoecology. There is a rare satisfaction in finding out about some of the *small* reptiles that have now been shown to have lived during the Age of the Dinosaurs. □

Archaeology

Stonehenge comes alive

From Julian Richards

THE antiquarians of the seventeenth and eighteenth centuries, the barrow diggers of the nineteenth, and the excavators, fieldworkers and astronomers of the twentieth have all been drawn to the Stonehenge area to observe, to dig and to speculate. To many it has long been apparent that the visible remains, barrows, henges and cursus monuments, while evidence of intensive and consistent activity during the Neolithic and Bronze Ages, provided only a partial picture of prehistoric society. Ideology and death left their enduring traces, but if we could see the dead, then where were the living?

"Stonehenge and Its Environs" (Edinburgh University Press) is the title of the survey carried out by the Royal Commission on Historic Monuments which has started to provide clues in the hunt for the living. Traces of now flattened prehistoric fields, small enclosures and boundary ditches point to an organization of the landscape beyond ritual and burial and provide an invaluable framework on which the next phase of investigation could be based. In 1980, the Trust for Wessex Archaeology began a programme of survey in the area of some 2,500 hectares studied by the Royal Commission. The overall brief of this Stonehenge Environs Project, commissioned by the Inspectorate of Ancient Monuments, was the location and evaluation of areas of prehistoric activity and the provision, by sample excavation, of firm indications of preservation for specific monuments.

With the exception of rare pockets of old grassland and woodland, and areas recently returned to grass by the National Trust, the arable landscape immediately dictated the most suitable field survey approach: surface collection 'field-walking'. The systematic collection of artefacts from the weathered surface of ploughed fields is becoming increasingly recognized as a major field survey technique. The use of flint and similar lithic material for tools throughout prehistory provides one enduring component of a total artefact assemblage that may also have included bone, metal and pottery.

The two-stage surface collection strategy used in this and other Trust for Wessex Archaeology projects aims initially to locate widespread patterns and anomalous areas. These are assessed in the light of localized topography and soil changes. Collection is initially by means of transects within hectare squares based on the national grid and provides an initial surface sample of approximately 8–10 per cent. The second stage of more detailed gridded collection tends to be reserved as an intensive pre-excavation sampling technique when it is carried out in conjunction with geophysical and geochemical surface surveys.

Over the past three winters more than 1,000 hectares have been examined and patterns of prehistoric activity have been recorded. Far from being a 'ritual landscape', devoid of inhabitants, the recent survey has shown areas of intensive domestic and industrial activity contemporary with the major ceremonial centres. Even within the relatively restricted study area, the patterns represented by the surviving monuments can be seen reflected in shifting zones of domestic activity culminating in the developed agricultural and territorial landscape of the later Bronze Age, *c.* 1000 BC.

Survey and sample excavation have thus provided a spatial, functional and chronological framework for prehistoric activity around Stonehenge, the only missing component being evidence for environmental change. The potential of upland chalk areas to provide environmental evidence is limited largely to land snails within protected contexts, particularly in buried soils and within ditch deposits. The palaeoenvironmental potential of the Stonehenge area, with its barrow mounds, ditches and other potentially dateable earth works, is thus extremely high and has been exploited in tandem with the main project. Research funding from the Society of Antiquaries, the British Academy and the Prehistoric Society has facilitated the investigation and analysis of a number of overlapping dateable environmental sequences.

The field aspects of the project are now almost complete, with only a short season of surface collection and recording of field monuments remaining. The project will then progress to a phase of full-time analytical work intended to produce both management strategies and a full synthetic publication of the projected results.

It is hoped to continue research in the area, particularly on the aspects of the prehistoric environment, but this will now depend on the availability of research funds other than from the UK Department of the Environment.

It is only by moving beyond empirical observations that we can hope to comprehend the societies in which Stonehenge was built. These must be understood if we are to preserve in a sensible manner their tangible, if ephemeral, remains. It is hoped that the Stonehenge Environs Project will not only have added to our understanding of the area, but also provided the means by which it can be both preserved and explained. □

Neurogenesis in *Drosophila*

Notch mapping function obscure

from Michael Akam

WHY does the *Notch* locus of *Drosophila melanogaster* attract so much attention, when the phenotype for which it is named is merely the generation of notches in the tips of the wings? The locus has for example now been cloned by two independent groups[1-3].

There are good reasons for this interest. Complete lack of function of the *Notch* locus results in a much more drastic developmental defect than notching of the wings — great increase in the proportion of ectodermal cells which become neuroblasts[4-7], consequentially an extensive hypertrophy of the nervous system at the expense of the epidermis and, eventually, the death of the embryo.

The notching phenotype is the dominant, but developmentally trivial, effect of heterozygosity for such a null mutation. Moreover, *Notch* is one of the best characterized of the genetically complex loci in *Drosophila*[5,8-12]. In addition to the dominant alleles, there are many recessive alleles which fail to complement *Notch* null mutations so that by conventional criteria they lie in the *Notch* gene. The phenotypes of these recessive mutations are varied. They include lethal mutations which have a range of lethal phases *(1(1)Notch)*, homozygous viable mutations which affect the morphology of the adult eye and bristles (*facet* and *split*) and *notchoid* mutations which, when homozygous, mimic the dominant phenotype of null alleles but have little or no effect on the nervous system. Mutations within any one of these classes generally fail to complement one another, but recessive mutations with different phenotypes often show total complementation. Thus by this test, each phenotypic class defines a different gene.

There are also *Abruptex* mutations. These have a dominant wing phenotype distinguishable from that of the null alleles; some are recessive lethals, some homozygous viable; in *trans* with other *Notch* complex mutations they may either enhance or suppress the *Notch* phenotypes.

Many of these mutations have been mapped by genetic recombination[8,9,11,12]. Recessive alleles and *Abruptex* mutations are interspersed with the null alleles, ruling out any possibility that the latter are deletions of several functional units. The genetic unit which they define is extremely large — 0.13 map units, or 19 times the genetic length of the xanthine dehydrogenase gene at the *rosy* locus[2].

The aims of the molecular studies at *Notch* are twofold: to understand the molecular basis of the genetic complexity and to identify the *Notch* products, and their role in neurogenesis.

The isolation and delimitation of the *Notch* complex was much facilitated by the numerous deletion and inversion mutations accumulated during decades of genetic analysis. Artavanis-Tsakonas and his colleagues noted that one deficiency[11] juxtaposed the *Notch* locus and a segment of the X chromosome which they had already cloned[1]. Thus it was one small step to hop into the complex. Both Artavanis-Tsakonas *et al.*[1,3] and Kidd *et al.*[2] report extensive chromosomal walks from this starting point. Both also map the location of chromosome breakpoints associated with *Notch* complex mutations, and regions of the complex homologous to transcripts. Kidd *et al.* report further the extensive analysis of the major *Notch* transcipt by two dimensional S1 mapping[2], and Artavanis-Tsakonas *et al.*[3] the isolation of cDNA clones derived from this major transcript.

Their results indicate that the *Notch* locus, like other complex loci in *Drosophila*[13], contains at least one long transcription unit with multiple introns, in this case spanning 35–40 kb. The genetic complexity reflects the complex organization of this transcription unit, but appears also to depend upon the particular characteristics of those mutations which result from the insertion of transposable elements.

There is a close correspondence between genetic and molecular maps. At *Notch*, one map unit corresponds to approximately 280kb of DNA, and *Notch* null mutations span 34kb. A spliced transcript longer than 10kb (ref. 1) and shorter than 11.5kb (ref. 2) is encoded throughout the region spanned by these *Notch* mutations. Kidd *et al.* have shown that it contains at least 8 introns ranging in size from < 1 to 20 kb, and find some heterogeneity at its 3′ ends[2]. One region at the 3′ end of this transcript contains a repetitive sequence which is homologous to other RNA species[3].

In several cases, mutations in the complex are correlated with the insertion of transposable elements into the locus. Four insertions which have given rise to *Notch* null mutations all lie in or very close to the exons of the major transcript[2]. In contrast, four recessive *facet* alleles and one recessive *Notch* lethal carry insertions within the major intron of this transcript[2,3]. Kidd and his colleagues speculate that stage or tissue specific transcription of the transposable elements in these mutations may result in the regulated inactivation of the *Notch* locus, and thus in the localized phenotype of the recessive mutations.

Shellenbarger and Mohler[10] suggested in 1975 that the diversity of the *Notch* complex recessive mutations results from the inactivation of a single *Notch* product at specific stages in development. This model, originally proposed to account for the interactions between temperature sensitive *Notch* mutations and the recessive alleles, accomodates remarkably well the molecular explanation now proposed.

By no means all *Notch* locus mutations result from insertions or gross rearrangements. The majority of both irradiation and chemically induced mutations were not detectably rearranged[1-3]. Most of these have however been mapped by recombination; using the correlation between genetic and molecular maps established for the insertion mutants, the majority of *Notch* null alleles can be assigned to the major exon at the 3′ end of the *Notch* transcription unit[2,3]. Thus they may be point mutations in a *Notch* protein.

From these data it seems that there is no necessity to postulate a multiplicity of products to explain the genetic complexity of the *Notch* locus. However, alternate splicing or processing pathways may yield a family of products from the major transcription unit, and that closely adjacent transcription units may be related to the function of *Notch*[1,3].

A very different molecular approach leads Thorig *et al.*[14,15] to suggest that the *Notch* complex is a multifunctional locus encoding a group of mitochondrial flavoprotein enzymes — NADH oxidase, NADH dehydrogenase, succinate dehydrogenase and glycerophosphate dehydrogenase. The activities of these enzymes in flies are dependent on the dosage of *Notch* genes, but the data indicating that *Notch* itself encodes these enzymes are not yet compelling. However, as Thorig *et al.* point out, the *rudimentary* locus of *Drosophila* exhibits a range of mutant phenotypes and complex complementation behaviour, and this locus is now known to be the structural gene for a polypeptide carrying three enzymes of pyrimidine biosynthesis[16].

In what sense then is *Notch* a gene controlling neurogenesis? Wright[5] suggested that the *Notch* product may be a repressor of neurogenesis — in the current parlance of *Drosophila* development, between epidermal and neurogenic pathways. Recent series papers make it clear that the situation is more complex. In a systematic search for mutations with embryonic phenotypes similar to that of *Notch*, Campos-Ortega and his colleagues[6,7,17,18] have identified six more 'neurogenic loci'. Lack of any one of these gene functions results in essentially the same developmental switch as that seen in *Notch* embryos — in extreme cases, all the cells in a large region of the ectoderm develop as neuroblasts, and no ventral cuticle is formed.

Michael Akam is an MRC Senior fellow in the Department of Genetics, Downing Street, Cambridge, CB2 3EH and a fellow of Kings College, Cambridge.

If indeed *Notch* does encode mitochondrial enzymes, then one factor affecting the determination of neuroblasts in insects may prove to be a critical balance in some metabolic state of the ectodermal cells. Most of the seven 'neurogenic loci' might then be genes whose products affect this balance. It is perhaps relevant that efforts to find the 'real' neural inductor in amphibians led to the conclusion that the ectoderm is finely balanced between epidermal and neural differentiation, and that many non-physiological stimuli could provide the trigger for neural induction[19].

If however, the products of the 'neurogenic genes' do encode such housekeeping products as flavoprotein enzymes, why is it that so many tissues of the *Drosophila* embryo differentiate apparently normally in their absence?

Whether or not the *Notch* gene makes an 'interesting' product, it is interesting to study the effects of mutation on this complex transcription unit. And lurking among the set of neurogenic loci that Campos-Ortega has identified, there may yet be a selector gene which monitors the state or position of each ectodermal cell, and mediates its developmental commitment. It remains to be seen whether the genetic and molecular analysis of these genes will elucidate their role in neurogenesis. □

Geochemistry

Chemical inhomogeneity of mantle above 670 km transition

from Don L. Anderson

WHAT chemical composition the mantle has and on what scale mantle convection takes place are related questions which require data from both seismology and petrology to answer. The mantle, which represents about 68 per cent of the Earth's mass, is usually considered, especially by petrologists, to be mostly homogeneous in composition. Discontinuities within it are generally assumed to represent isochemical phase changes in an olivine-rich material rather than chemical boundaries. Thus, the 400 km and 670 km boundaries detected by seismic means are taken to represent the 'olivine-spinel' and 'spinel-post-spinel' phase changes, respectively. The 670 km discontinuity is the more significant, for seismic velocities increase greatly at this depth. This boundary must be very sharp as it is both a good reflector of short-period seismic waves and is the lower boundary of earthquake activity — no reliably-located earthquake has ever been found below it. These observations can be used to argue that the '670' is a chemical interface that provides a barrier to convection.

A.C. Lees, M.S.T. Bukowinski and R. Jeanloz (*J. geophys. Res.* **88**, 8145; 1983) have recently computed the reflection coefficient for a variety of plausible phase changes and conclude that mineralogical and seismic data are compatible with a two-layered mantle that has a discontinuous change in both phase and composition at 670 km, and that the change in material properties must occur over a region less than 3 km thick. Phase changes are typically spread out over a much greater depth interval and give reflection coefficients more than an order of magnitude less than those observed. This conclusion is not new but it serves to keep up the pressure on those who advocate that the mantle is chemically uniform and is involved in convection as a whole. Although the nature of the 670 km discontinuity is important, Lees and colleagues' results may produce a yet more significant conclusion.

They calculate the velocity in the transition region for olivine, for orthopyroxene and olivine and for garnet mineral assemblages, including the effects of phase changes. The velocities in all these minerals and assemblages are much greater than the seismic velocities in the transition region and there is no similarity in shape or depth between the mineralogical models and the 400 and 670 km mantle discontinuities. Taken at face value, these results would seem to rule out peridotite, pyrolite or any olivine-orthopyroxene rich assemblage for the 400–670 km depth interval and the olivine-spinel-post-spinel explanations for mantle discontinuities. Although the temperature and temperature gradient can be adjusted to give a fair match of olivine-rich aggregate densities with the seismically-determined density, the much more accurately determined velocities are poorly matched. The velocity and density gradients of the transition region are greater than calculated for the peridotite minerals. A spread-out phase change or a compositional gradient is implied.

Lees and colleagues do not pursue these discrepancies in the region above 650 km. They restrict themselves to conventional mineralogies involving $(Mg,Fe)_2SiO_4$, $(Mg,Fe)SiO_3$ and $(Mg,Fe)_3Al_2Si_3O_{12}$. They assume that the MgO, FeO and SiO_2 contents of mantle silicates control the physical properties and the locations of phase boundaries, but, as usual, the effects of CaO, Al_2O_3 and Na_2O are ignored. These are minor components of peridotite and pyrolite minerals, the presumed dominant minerals of the mantle. Eclogite, an alternative mineralogy for the transition region, is dominantly clinopyroxene (diopside and jadeite) and garnet, transforming gradually to garnetite ($CaO–Al_2O_3–Na_2O$-rich garnet solid solution) over the pressure interval of the transition region. Unfortunately, velocities in an eclogite transition region, including phase changes, are not treated, in spite of the obvious discrepancies with the peridotite minerals.

The idea of a peridotite mantle dominated by olivine is deeply entrenched in geology. Olivine and ortho-pyroxene are dominant minerals in xenoliths brought to the surface in alkali basalts and kimberlites and in upthrusted segments of the mantle exposed in fold belts and oceanic fracture zones. The most abundant rocks emerging from the mantle, however, are basalts. At high pressure, these rocks are composed mainly of garnet and clinopyroxene — they are eclogites. At one time it was thought that the upper mantle and the source region of basalts were primarily eclogite. More recently, it has been assumed that the basalt-eclogite fraction of the mantle is dispersed and is liberated by 20–30 per cent partial melting, leaving behind a refractory olivine-orthopyroxene-rich residue. The fact that olivine-orthopyroxene aggregates cannot explain the 400 and 670 km discontinuities, and the velocity and velocity gradients in the transition region, will force a reexamination of the basalt source region, the chemical uniformity of the mantle, and the composition of this region of the mantle.

It is also important to look at clinopyroxene-garnet-rich assemblages. Lees *et al's* inability to match the compressional velocity is particularly significant because theirs is not an *ab initio* calculation. They used the seismic data themselves to constrain the velocity-bulk modulus ratio. Those who would argue for a chemically uniform mantle and an olivine-rich transition region are now faced with a formidable array of contrary evidence. □

Living plant fossils

SIR — The article "Seeds of thought for plant conservationists" by P.D. Moore[1] is of great interest but it should be added that seeds are not the only plant reproductive parts that remain viable over a considerable period of time in datable contexts. The same is true of fungal mycelia and spores[2], bacteria[3,4], apparently not viruses[5] but probably algae, which can survive as cysts.

Moore[2] isolated 61 microfungi from two peat profiles collected in the Dublin-Wicklow mountains, Ireland, using Warcup's soil plate method. More viable remains occurred at the surface but the number of viable taxa (6 or 7) was constant with depth. Unfortunately the peats have not been dated by radiocarbon methods.

Bacteria of the thermophilic actinomycete genus *Thermoactinomyces* are relatively easily isolated and identified[5]. Their resistant endospores survive for longer than 1,500 years in anaerobic lake muds[3] and have been cultured using occupation debris from the Roman fort site of Vindolanda, Northumberland[4]. The concentration of colonies grown varied with sediment type. The microbiology of grain stored in Iron Age-type pits has also been studied[7] as part of an experimental project on agricultural practices.

Conservation should not be confined solely to higher plants and the medical value of *Penicillium* is a good indication why. Soils that are totally anaerobic or clay-rich (holding water tightly in the clay-humus bond) may serve as storehouses of viable remains of lower plants in addition to seed banks, as Moore suggests.

Definition of extinction in lower plants may be even more difficult than for angiosperms, given the possible longevity of spores.

The palaeoecological importance of these findings requires stressing. While little research on fossil Holocene microfungal remains has so far been carried out in Europe, interest may grow if it can be demonstrated that data which add to interpretations of vegetation history based on pollen analysis may thereby be acquired. Microfungi are impossible to identify taxonomically using mycelial remains preserved in peats, and accurate determination using the various spore types is very difficult[8], but if viable remains occur the prospects are much better.

The various spore types of *Ceratocystis ulmi* (Dutch elm disease) are extremely small[9] and are probably not identifiable by light microscopy. Finds of fossil elm bark beetles would provide no proof that they were carrying the disease. However, if *C. ulmi* spores remained viable for 5,000–5,200 years, the theory that the elm decline in the British Isles was due wholly or partly to this disease could be properly tested. It has already been shown[6] that *Thermomycetes vulgaris* (actinomyces) spores are plentiful in samples from Seamere, Norfolk, which have cereal and associated weed pollen and *Thermomycetes spp.* occur today in association with cereal cultivation and storage.

Finally, it is of note that Seaward *et al.*[4] found viable endospores of *T. vulgaris* and *T. dichotomica* at Vindolanda differing from those regarded as typical of currently recognized species. So resuscitation can add potentially to genetic diversity.

Plants from culture

SIR — Recently there has been an increasing amount of research on the inheritance of characters in the progeny of tissue culture-derived plants. Genetic analyses of this type are likely to become even more common as the techniques for generating (somaclonal) genetic variants and transformants via tissue culture become more widely applied to crop species. In discussing results of this type of research, it has come to our attention that there is a potential source of confusion in the nomenclature used.

It is common practice to self-pollinate plants regenerated from culture and to analyse the resulting progeny for the inheritance of novel traits. The progeny of such selfed regenerated plants have been referred to variously as the F_1, F_2, R_1, R_2, RF_1, RF_2, SC_2, S_1 and G_1 generation[1–9]. It is therefore apparent that a consistent nomenclature is needed to clarify the nature of the material being described.

Ideally any system adopted should be logical, easy to use and be compatible with established plant breeding nomenclature. We believe that these criteria can be met by strict adherence to the use of letters to designate the process, followed by numbers to show how many times the process has been performed. Thus the original regenerated plants are to be referred to as the R_1 generation. It follows that successive cycles of cell culture and plant regeneration, without a sexual cycle, would produce R_2, R_3, etc. generations. If the regenerated plants from the R_1 generation are selfed, their progeny become the R_1S_1 generation. Repeated selfing to eventually produce homozygous inbreds would progress through the R_1S_2, R_1S_3, R_1S_4, etc. generations. Back-crossing to non-cultured material would similarly be described as R_1BC_1, R_1BC_2, R_1BC_3, and so on. By using nomenclature that is compatible with current plant breeding conventions, the same system can easily be extended to more complex breeding programmes. For example, using maize inbreds, (Mo17 × B73 R_1S_1) BC_2 would represent the second backcross generation derived from the cross of Mo17 by an S_1 progeny of a plant regenerated from a B73 culture. Although such complex situations would not be met by most researchers, we feel that any system adopted should be able to cope with all eventualities.

Species named

SIR —It is surely of fundamental importance in research work in the areas of basic biology and genetics that the organisms being studied should be precisely identified. I find it extraordinary, therefore, that in the interesting article by Bernards *et al.* on the growth of chromosome ends in trypanosomes (*Nature* **303**, 592; 1983), that neither the genus nor the species of the trypanosomes studied was given.

DAVID WALLIKER
Institute of Animal Genetics, University of Edinburgh, Edinburgh EH9 3JN, UK

BERNARDS AND BORST REPLY — Our experiments were done with *Trypanosoma brucei brucei*, strain 427. We expect, however, that the growth and contraction of chromosome ends will be a property of chromosomes in all African trypanosome species, and possibly in all organisms. We apologize that this expectation has inadvertently crept into our paper and we hope that other readers have found the missing information in our earlier papers, amply quoted in the *Nature* article.

What is the solution?

SIR — The centenary of Sydney Ringer's important work[1] on the ionic requirements for maintenance of viability of living tissues *in vitro* has, astonishingly, been unremarked; it was not even mentioned at the recent 29th International Congress of the International Union of Physiological Sciences in Sydney, Australia. In the same field we are approaching the 75th anniversary of Tyrode's contribution[2] and have just passed the 50th anniversary of the advance made by Krebs and Henseleit[3]. The use of Ringer's, Tyrode's and Krebs' solutions in biomedical research must be among the most common techniques of science, perhaps even rivalling Student's *t*-test. I estimate that Krebs' solution alone features in more than 10,000 scientific papers a year.

These solutions, and their better nourished relatives, the tissue culture media, represent a veritable scientific Ganges. They have become holy waters, with all of the associated mysticism, dogma, priesthoods and devout acolytes. Nostrums from the ancient scriptures, frequently mistranslated to include idiosyncratic errors, are being perpetuated unquestioningly through generations of disciples. There have even been attempts at minor deification with the eponyms "Ringer" and "Krebs" being applied, respectively, to almost any such solution and to bicarbonate/CO_2 buffered solutions in particular. It has been forgotten that the tissue sustaining properties of normal saline were known before Sydney Ringer and that bicarbonate/CO_2 buffered salines were in use before Krebs and Henseleit.

But none of these solutions was designed to simulate the natural bathing fluid of tissue cells, the *milieu intérieur* of Claude Bernard. All were based on what was known of blood plasma composition and were adjusted empirically to produce a desired response. This has resulted in the use of solutions which maintain grossly abnormal *p*H, electrical potential and osmotic equilibrium in the isolated tissues they support. Because such phenomena as cellular excitability, drug–receptor interaction and enzyme activity may be profoundly affected, why do these solutions continue to be used?

Certainly, there are occasional glimmers of awareness, as a few authors each year notice some of the unphysiological characteristics of Krebs', Tyrode's and Ringer's solutions. These continual rediscoveries have resulted in a multiplicity of slightly "modified" solutions. The fact that each of these is capable of maintaining tissues in a reasonably functional state should not be surprising. Living cells have to cope with the fluctuations produced by water intoxication or dehydration, high or low salt intake, labile *p*H and such ionic imbalances as result from muscle exercise during marathon running, for example. Nor should it be surprising that some cellular functions are best demonstrated in solutions with defined, even highly abnormal, compositions. But, if our objective is to gain insight into *in vivo* function, we should expect normal cellular function only in cells coping with environmental conditions close to normal.

Is there a fundamentalist conspiracy promoting a scotomatical attitude among biomedical scientists so that even those who are in the forefront of the giga-ohm-laser-dye-coupled-computerized-tomographic-recombinant-DNA style of cellular research continue to use string and sealing wax technology for their "physiological bathing solutions"?

I espouse heresy. In 1969, I devised a solution based quantitatively upon the ionic composition of a representative mammalian interstitial fluid[4]. This I termed synthetic interstitial fluid (SIF) and it has been used with great success in many laboratories, notably in experiments on isolated human and other mammalian muscles. SIF may not be the ultimate in physiologically balanced salt solutions but it certainly surpasses those now being used.

ITP nomenclature

SIR — The interesting recent letter *Nature* (3 November, 1983 p.67–69) and News and Views article (3 November, p.16–17) on the possible second messenger function of inositol 1,4,5-trisphosphate may presage a surge of interest in the function and metabolism of inositol phosphates. It would therefore be helpful immediately to establish acceptable and unambiguous abbreviations of these compounds. Streb *et al.* did to a large degree achieve this aim; for example, they used Ins 1,4,5P_3 to indicate inositol 1,4,5-trisphosphate. However, they unfortunately chose cyclic IMP as their abbreviation for inositol 1,2-cyclic phosphate: their own logic would demand the abbreviation Ins1,2-cyclicP, and cyclic IMP would normally be taken to mean inosine 3, 5-cyclic phosphate.

Hesketh's News and Views item was less careful: the inositol lipids were referred to by the outdated PI and PI-4,4-bisphosphate terminology, rather than as PtdIns and PtdIns4,5P_2, and Ins1,4,5P_3 appeared as ITP, which is internationally accepted as an abbreviation for inosine triphosphate. Although the abbreviations in which inositol appears as Ins are more cumbersome, they are unambiguous, and this is a great virtue in a field into which many new workers are moving.

Another flaw in the published material was the incorrect citation of our recent paper (ref. 5 of the News and Views item): the correct citation is *Biochem. J.* **212**, 733–747; 1983).

Familial cancers

SIR — Several reports have recently appeared showing that familial retinoblastoma is due to mutations in each of the two copies of an autosomal gene. In a review of this work in *Nature*[1] your reviewer, like most people writing about the genetics of retinoblastoma, implies that Alfred Knudson was the originator of the idea that certain familial cancers such as retinoblastoma could be due to the combination of an inherited mutation and a somatic mutation. Actually this hypothesis was proposed by Robert de Mars in a symposium organized by the University of Texas M.D. Anderson Hospital[2], two years before Knudson's first paper on the subject.

Until then, familial retinoblastoma had been classified as due to an autosomal dominant mutation, but de Mars made the following point: ". . . I suggest that many of the pedigrees that are labelled as autosomal dominants . . . could actually be interpreted as autosomal recessives. We must relate the terms dominant and recessive not only to the level of the individual as a whole . . . but also to the level of the individual cell, or cells, which are involved. I think many pedigrees are consistent with the notion that one of the parents in these families might be heterozygous for a recessive and that the neoplasms appear as a result of subsequent somatic mutations in which individual cells become homozygous for a recessive neoplasm-causing gene."

Aspherical heterogeneity of the mantle from phase velocities of mantle waves

Ichiro Nakanishi & Don L. Anderson

Seismological Laboratory, California Institute of Technology, Pasadena, California 91125, USA

Long-period surface waves are used to map the lateral heterogeneity of the upper 100–600 km of the mantle. There is good correlation of velocity with surface tectonics and heat flow. Convergence regions are generally slow for Love waves and fast for Rayleigh waves. Back arc basins have slower than average shallow mantle. Some island arcs show evidence of fast material at greater depth. Deep-seated slow anomalies underlie the Red Sea–Afar region of north-east Africa, western North American–northern East Pacific Rise, Indian Ocean triple junction and the Tasman Sea–Campbell Plateau regions. The fastest regions are in the north central Australia–New Guinea and the South Atlantic.

SURFACE waves or, equivalently, short-period free oscillations are sensitive to the seismic velocities and density of the upper mantle and provide a powerful method for mapping lateral heterogeneity of this part of the Earth.

We have measured surface wave phase velocities over about 300 paths by applying a single-station method[1] to long-period fundamental-mode Love (G) and Rayleigh (R) waves from 13 large earthquakes. We assume that surface waves propagate along the great circle path connecting an earthquake and a station and that they can be expressed as travelling waves generated from a double-couple point source. In this study we measured apparent phase velocities of G_2, G_3, R_2 and R_3, and thus have information for both long and short arcs.

We expand the measured velocities in spherical harmonics to avoid an *a priori* association with surface tectonics. A motivation of this study and our previous study[2] is that the commonly used great circle velocity measurement method[3], or, equivalently, the free oscillation method[4] gives only the even-order terms of a spherical harmonic description of the Earth's lateral heterogeneity[5,6]. This information, of course, is not sufficient to describe adequately the heterogeneity. The single-station observations provide the missing information, although the measurement accuracy is inferior to that of the great circle observations. To suppress the instability due to the poorly determined odd harmonics we apply a filtering procedure to the inverted spherical harmonic coefficients[7,8]. Finally, we correlate the resulting phase velocity distribution with surface tectonics, heat flow and the geoid. A detailed description of our single-station velocity measurements, filtering procedure and interpretation, will be presented elsewhere (ref. 7 and C. H. Nataf, I.N. and D.L.A., in preparation).

Single-station velocity measurement

We processed long-period fundamental-mode surface waves generated from 13 large shallow earthquakes recorded on long-period digital networks (IDA and GDSN). The transversely rotated horizontal and vertical component seismographs are used for analysing Love and Rayleigh waves, respectively. The number of individual paths (short arc plus long arc) is larger than about 300 for both waves. The great circle paths for Rayleigh waves are shown in Fig. 1*b*. Coverage is less complete for Love waves.

For the single-station method we have to incorporate information about the source process. In this study we correct the source effect by using source mechanisms and source process times obtained by Nakanishi and Kanamori[9]. The directional part of the source finiteness is ignored. Epicentral locations and origin times are from the National Earthquake Information Service.

To calculate the distance along the great circle path we assume a geometric flattening $fg = 1/297.001$ and a mean radius $R_0 =$ 6371.211 km. We do not correct for the frequency dependent ellipticity[10–12]. This correction does not affect the conclusions of the present article[8].

Geographical variation

We expand the phase slowness $1/C(\Omega, \omega)$ in terms of spherical harmonics:

$$1/C(\Omega, \omega) = \sum_{l=0}^{\infty} \sum_{m=-l}^{m=l} s_{lm} Y_{lm}(\Omega) \quad (1)$$

where $\Omega = (\theta, \phi)$, ω is the angular frequency, and $Y_{lm}(\Omega)$ are the fully-normalized spherical harmonics. We truncate equation (1) at $l = l_{max}$ and write the observed phase delay along the propagation path

$$t_{ES} = \sum_{l=0}^{l_{max}} \sum_{m=-l}^{m=l} S_{lm} \int_E^S Y_{lm}(\Omega)\, ds \quad (2)$$

If the number of observations is much larger than the number of coefficients s_{lm}, and the surface wave paths are well distributed over the Earth's surface, we can determine the coefficients s_{lm} by solving equation (2) in a least-squares sense and can synthesize $C(\Omega, \omega)$ by equation (1).

We processed G_2, G_3, R_2 and R_3. G_2 and R_2 travel the long arc between source and receiver. G_3 and R_3 travel in the opposite direction and travel the short arc and one complete additional orbit. To calculate the path integral of Y_{lm} in equation (2) for these waves, we used Backus' solution[5] of the great circle integral of spherical harmonics and numerical evaluation of the integral for G_1 and R_1.

We solved equation (2) and determined s_{lm}. Since $l_{max} = 8$ inversion does not appreciably improve the fit over the $l_{max} = 6$ inversion[7], we discuss the solutions for $l_{max} = 6$. We could synthesize $C(\Omega, \omega)$ by straightforward application of the sum formula (1). The coefficients of $l =$ odd, however, have larger uncertainties than those of $l =$ even harmonics. To suppress the contribution of the poorly constrained odd harmonics we apply a filter based on the method of Whaler and Gubbins[13].

Figure 2 shows the filtered velocity contour maps for Love waves at for 100, 153, 200 and 250 s. The overall pattern of the Love wave phase velocity variations shows a general correlation with surface tectonics. These waves are most sensitive to the S_H velocity in the upper 200 km (153 s) to 300 km (250 s) of the mantle.

The lowest velocity regions are located in the southeastern Pacific, western North America, north-east Africa centred on the Afar, the central Atlantic, the central Indian Ocean, and the marginal seas in the western Pacific. A high-velocity region is located in the north central Pacific, centred near the Hawaiian swell. Love wave phase velocities are low along portions of the

© 1984 Macmillan Journals Ltd

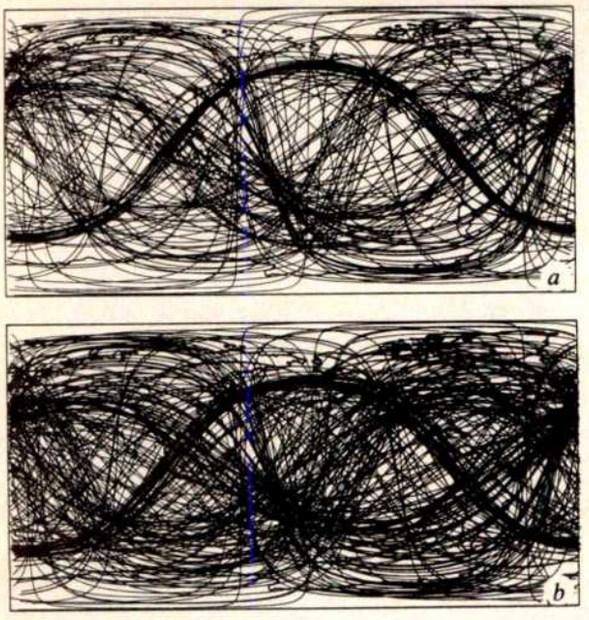

Fig. 1 Great circle paths for Love wave (*a*), Raleigh wave (*b*) observations. The same map projection as Figs. 2, 3, 4 and 6.

Mid-Atlantic Ridge, especially near the triple junctions in the north and south Atlantic.

High-velocity regions in continents generally coincide with Precambrian shields and Phanerozoic platforms (northwestern Eurasia, western and southern parts of Africa, eastern parts of North and South America, and Antarctica). Tectonically active regions, such as the Middle East centred on the Red Sea, eastern and southern Eurasia, eastern Australia and western North America are slow as are island arcs, such as the southern Alaskan margin, the Aleutian, Kurile, Japanese, Izu–Bonin, Mariana, Ryukyu, Philippine, Fiji, Tonga, Kermadec and New Zealand arcs.

Rayleigh wave phase velocities are presented in Fig. 3. Rayleigh wave phase velocity also correlates well with surface tectonics, particularly at short periods. The periods considered in this study are most sensitive to S_V velocity between about 100 and 400 km (153 s) to 600 km (250 s) and thus sample deeper than the Love waves.

The slowest regions, for Rayleigh waves, are centred on the Red Sea–Afar, Kerguelen–Indian Ocean triple junction, western North America centred on the Gulf of California, the north-east Atlantic, and Tasman Sea–New Zealand–Campbell Plateau. The fastest regions are the western Pacific, New Guinea–western Australia–eastern Indian Ocean, west Africa, northern Europe and the Southern Atlantic.

One difference between Love waves and Rayleigh waves is evident in the island arcs along the northwestern margins of the Pacific Ocean, such as the Aleutian, Kurite, Japanese, Izu–Bonin–Mariana, Ryuku and Philippine regions. These regions are characterized by the high velocity of the Rayleigh waves. An exception is the Aleutian region for a period of 250 s. In the contour map for 250 s (Fig. 3*d*) a high-velocity region occurs near the Izu–Bonin–Mariana trenches. The difference between Love and Rayleigh wave results may be explained by the difference in penetration depth. The Love wave results indicate that the shallow mantle, in the vicinity of island arcs and back-arc basins, is slow. Rayleigh waves sample the fast material which has subducted beneath the island arcs. Because of the large wavelengths, the lateral extent of the fast material must be considerable. Anisotropy may also be involved. In regions of convergence and divergence the mantle flow can be expected to be generally vertical. In the centres of convection cells, the flow is mainly horizontal. The sense of anisotropy will change

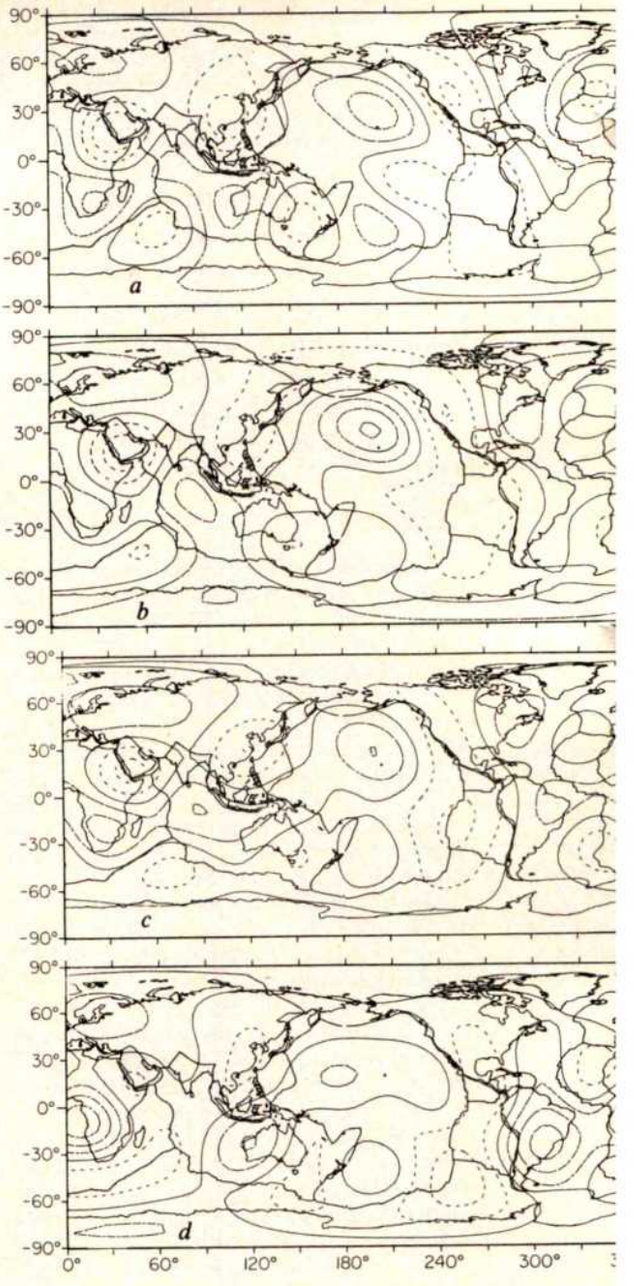

Fig. 2 Love wave phase velocity distributions synthesized by usi
$l = 1$–6 terms. The solid, chain and broken lines indicate spheri
average, higher than average and lower than average velocity. T
contour interval is 0.05 km s^{-1}. *a*, 100 s; *b*, 153 s; *c*, 200 s; *d*, 250

at ridges and subduction zones. This point will be analyse
detail elsewhere.

For Rayleigh waves the Atlantic Ocean is generally
velocity except for the northern part. The low velocities as
ated with the mid-oceanic ridge system, which appear in
Love wave maps, are not evident in the long-period Ray
wave maps. This may indicate that many ridge segments
passive or that $S_V > S_H$ in regions of ascending flow.

Heat flow and geoid

Heat flow and geoid maps have been presented in term
spherical harmonics and comparison with our surface
results is straightforward. For this purpose we use the heat
distribution of Chapman and Pollack[14] and the GEM 8 ge
corrected for the hydrostatic figure of the Earth[16]. Chap
and Pollack used observed heat flow supplemented by a tec

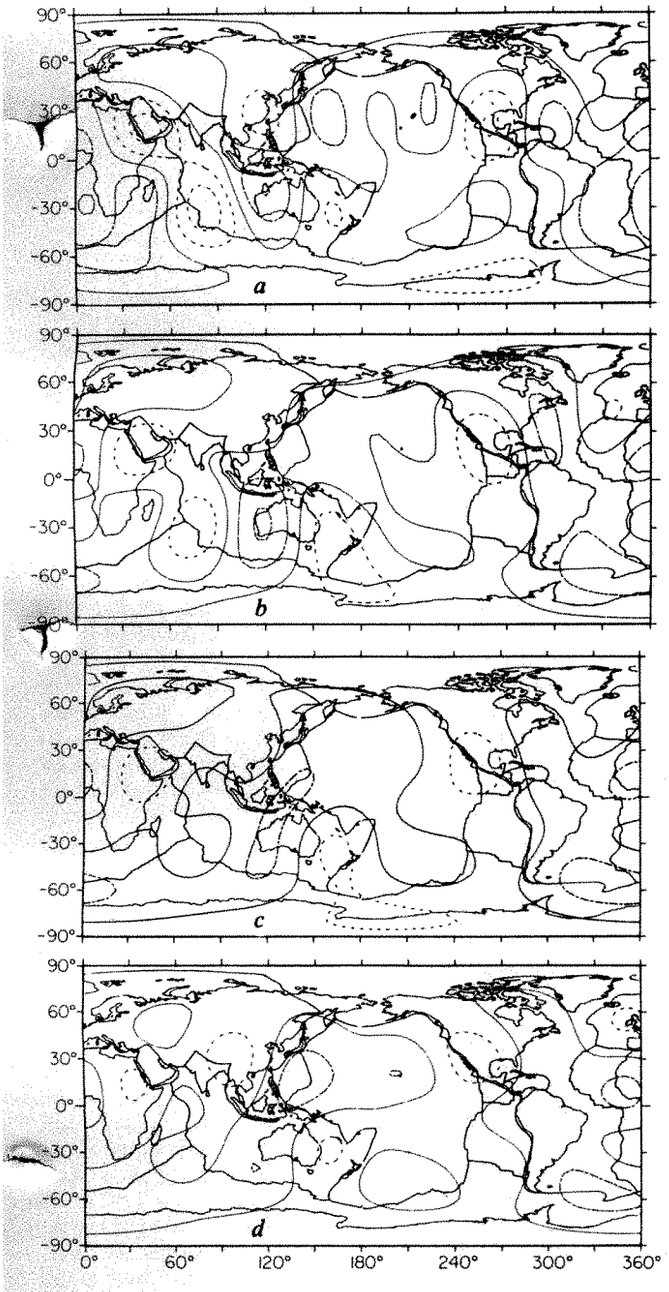

Fig. 3 Rayleigh wave phase velocity distributions synthesized by using $l = 1$–6 terms. The symbol convections are the same as in Fig. 2. *a*, 100 *s*; *b*, 153 s; *c*, 200 s; *d*, 250 s.

predictor. Figure 4*a* and *b* show the heat flow and geoid maps truncated at $l = 6$.

Figures 2–4 show that the phase velocities, especially Love waves, are well correlated with heat flow and, therefore, surface tectonics. The geoid has a weaker correlation with the surface wave velocities.

We compute the degree correlation coefficients γl for $l = 1$ to 6 by

$$\gamma_l = \frac{\sum_{m=-l}^{m=l} S_{lm} t_{lm}}{\left(\sum_{m=-l}^{m=l} S_{lm}^2\right)^{1/2} \left(\sum_{m=-l}^{m=l} t_{lm}^2\right)^{1/2}} \quad (3)$$

where S_{lm} and t_{lm} are coefficients for surface waves and for heat flow or geoid. The results are shown in Fig. 5. The heat flow

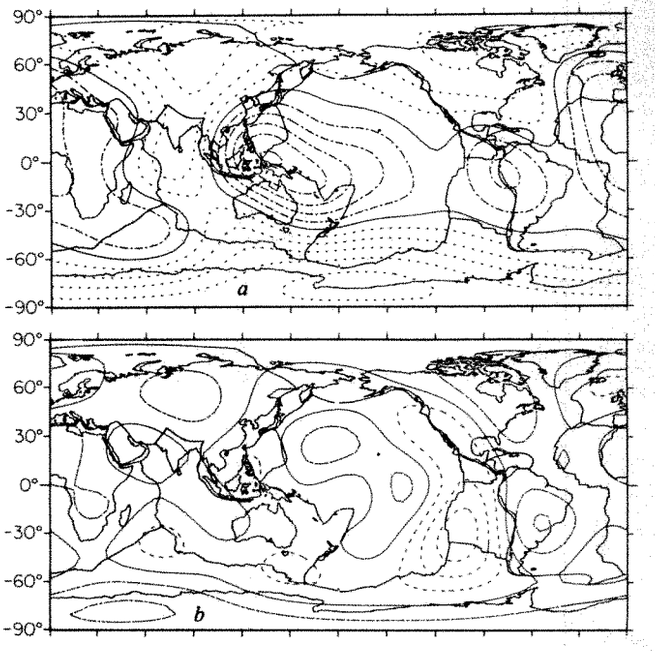

Fig. 4 Contour maps of heat flow and the geoid. *a*, Non-hydrostatic geoid (GEM 8) of Wagner *et al.*[15] and Nakiboglu[16]. The contour interval is 20 m. $l = 2$–6. The solid, chain and dashed lines indicate the spherical average, higher and lower geoid. *b*, Heat flow of Chapman and Pollack[14]. The contour interval is 10 mW m^{-2}. $l = 1$–6. The solid, chain and dashed lines represent the spherical average, lower and higher heat flow, respectively.

has positive correlation with phase slowness for degrees from 1 to 6. The geoid shows negative correlation at $l = 2$ (Love and Rayleigh) and 3 (Rayleigh), and positive correlation at $l = 4$ to 6.

The correlation of heat flow with Love wave velocities can also be seen by comparing Figs 2 and 4. Because the heat flow map is based on tectonics, as well as heat flow data, this comparison indicates that upper mantle velocities correlate with surface tectonics. Shields are low heat flow areas and exhibit high Love wave velocities, in spite of the thick low-velocity crust. From our Love wave map we would predict that south-east Asia and the Afar region are characterized by more extensive heat flow highs than predicted by Fig. 4*b*. These regions have few heat flow observations. The Canadian Shield and Siberian Platform anomalies are less evident in the Love wave maps than in the heat flow map.

The correlation between surface wave velocities and the geoid is weak. Geoid highs are associated with both subduction and hotspots. Ridges are not evident in either the long wavelength geoid or Rayleigh wave maps. The $l = 2$ correlation indicates that the long wavelength part of the geoid has a negative correlation with slowness, that is $l = 2$ geoid highs correlate with $l = 2$ velocity highs. For shorter wavelength features the reverse is true.

Discussion

Love waves are sensitive to the S_H velocity of the shallow mantle, above about 300 km for the periods considered here. The slowest regions are at plate boundaries, particularly triple junctions. Slow velocities extend around the Pacific plate and include the East Pacific Rise, western North America, Alaska–Aleutian arcs, south-east Asia and the Pacific–Antarctic Rise. Parts of the Mid-Atlantic Rise and Indian Ocean Rise are also slow. The Red Sea–Gulf of Aden–East African Rift (Afar triple junction) is one of the slowest regions. The upper mantle velocity anomaly in this slowly spreading region is as pronounced as under the rapidly spreading East Pacific Rise. Because it also shows up

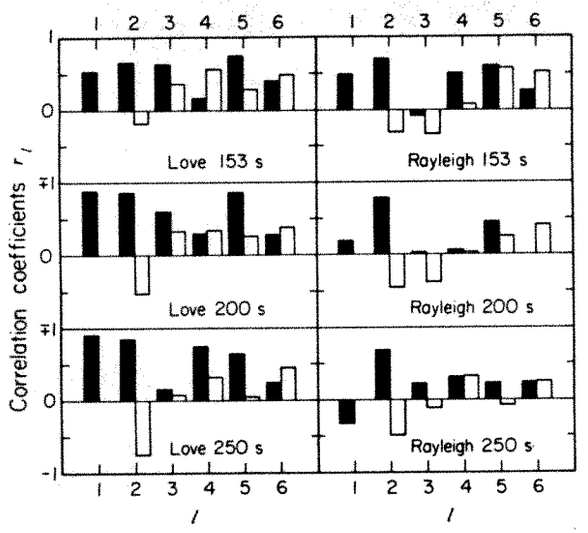

Fig. 5 Degree correlations of surface wave slowness with heat flow and geoid. Solid bars are correlations with heat flow. Open bars are correlations with geoid.

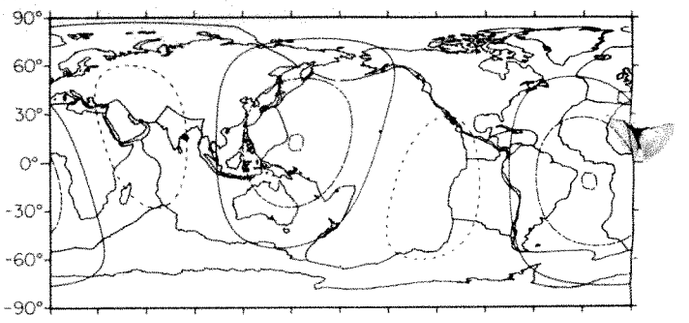

Fig. 6 $l=2$ map of 250-s Rayleigh wave phase velocity. The symbols are the same as in Fig. 2. Rayleigh waves of this period are most sensitive to S_V velocities between depths of 150 and 600 km.

for long-period Rayleigh waves, this is a substantial and deep-seated anomaly. Shields are generally fast, particularly the Brazilian, Australian and South African shields. The fastest oceanic regions are the north-central Pacific, centred near Hawaii, and the eastern Indian Ocean.

Rayleigh waves are sensitive to shallow P-velocities and, for the periods considered here, S_V velocity from about 100 to 600 km. The fastest regions are the western Pacific, western Africa and the South Atlantic. Western North America, the Red Sea area, south-east Asia and the north Atlantic are the slowest regions.

The Precambrian shields are generally faster than average. Silver and Joran[17] distinguish between shields and stable platforms. Okal's regionalization[18], a more suitable model for great circle Rayleigh wave phase velocities[18,19], combines these two tectonic regions and has a separate region for island arcs. If we adopt Okal's model, we obtain slower than average Rayleigh wave phase velocity at long period for the stable continental areas[8,18,19]. In Fig. 3*c* the velocities in the South Atlantic and the Philippine Sea plate are faster than shields.

Regions of convergence, or descending mantle flow, are relatively fast for long-period Rayleigh waves, particularly near New Guinea, Sumatra, western and northwestern Pacific. These regions have large positive geoid anomalies. Dense, cold material in the uppermantle can explain these results. To explain the surface wave results the fast material must be below the depth sampled by 250-s Love waves and 150-s Rayleigh waves, which is ~300 km depth, and must occupy a considerable volume of the upper mantle. Conductive cooling of the oceanic lithosphere probably extends no deeper than ~150 km. It is doubtful that the subduction of such a thin high-velocity plate could explain the present results and those of our previous regionalization study[8]. Either slabs preferentially subduct in cold regions of the mantle or they pile up in the upper mantle. At shorter periods the velocity of the mantle beneath subduction zones is average or slower than average, presumably reflecting the extensional tectonics and hot shallow mantle under back arc basins. In the tectonic regionalization study of Nakanishi and Anderson[8], it was also shown that convergent regions are faster than shields at long periods.

It has been proposed that the $l=2$ term is the dominant component of the Earth's asphericity and that it is caused by heterogeneity in the transition region, 420–670 km (ref. 4). Furthermore, it was suggested that the $l=2$ transition zone model was superior to tectonic regionalization. The tectonic model chosen[17], however, ignores convergence regions. A scheme which includes these regions[18] gives results which are similar to spherical harmonic inversions[8,20] and show, in addition, that odd harmonics are important. This study shows that there are large lateral variations in the shallow mantle. These plus variations in crustal thickness and water depth are not accounted for in the transition zone model[4] which attributes *all* of the observed variation to inhomogeneity of the 420–670 km depth range of the mantle.

A map synthesized from the $l=2$ coefficients at 250 s (ref. 8) is given in Fig. 6. This is characterized by a broad closed high-velocity region centred in the western Pacific, north-east of New Guinea, and a slow velocity region centred on the East Pacific Rise. Because of symmetry the antipodal regions are identical. This map is similar to that presented by Masters *et al.*[4] but our interpretation is quite different. Because the pattern is similar at short periods[8,20] it is the shallow mantle as well as the transition region that controls the pattern. In particular, the East Pacific Rise and the Red Sea areas control the location and shape of the lows in the $l=2$ pattern and the fast velocities in the western Pacific–Australia determine the location of the velocity highs. The $l=2$ coefficients are just part of the complete set that is required to describe fully the Earth's asphericity and need no special explanation. The $l=2$ pattern of the associated density field does have special significance because it is involved in the Chandler wobble, tidal friction, the orientation of the Earth's spin axis and polar wander, but again there is no reason to suppose that the $l=2$ pattern requires a special explanation. The tectonic model of Okal[18], for example, based on surface tectonics, has a strong $l=2$ component. The strong $l=2$ component comes from the ocean–continent configuration, the locations of island arcs, and the thermal structure of the sea floor. In particular the velocity highs in Fig. 6 encompass most of the world's old oceanic lithosphere and convergence regions and the lows include most of the young oceanic lithosphere and many of the world's hotspots. The correlation between surface wave velocity and heat flow (that is tectonics) and between velocity and geoid is relatively high for $l=2$, particularly at long periods (Fig. 5). If the rotation axis of the Earth is controlled by density anomalies in the upper mantle, and if density correlates with velocity, then the pattern in Fig. 6 would be symmetric about the Equator.

The most important results of the present study are: (1) discovery of low-velocity anomalies centred on south-east Asia, Afar and the Gulf of California and the demonstration that the latter two persist to long periods, indicating a deep upper mantle origin; (2) the association of high velocities, at long periods, with the western Pacific subduction zones, indicating a large volume of fast material in the upper mantle and; (3) the high velocities in the South Atlantic which do not have an obvious explanation in terms of present plate configurations. The South Atlantic may be underlain by ancient subducted Pacific Ocean lithosphere.

We thank Henri-Claude Nataf, Hiroo Kanamori, and Bradford Hager for suggestions. Jeffrey Given, Fumiko Tajima, and

Frost rings in trees as records of major volcanic eruptions

Valmore C. LaMarche Jr* & Katherine K. Hirschboeck†

* Laboratory of Tree-Ring Research and † Department of Geosciences, University of Arizona, Tucson, Arizona 85721, USA

New data about climatically-effective volcanic eruptions during the past several thousand years may be contained in frost-damage zones in the annual rings of trees. There is good agreement in the timing of frost events and recent eruptions, and the damage can be plausibly linked to climatic effects of stratospheric aerosol veils on hemispheric and global scales. The cataclysmic proto-historic eruption of Santorini (Thera), in the Aegean, is tentatively dated to 1628–26 BC from frost-ring evidence.

VERY occasionally, a major explosive eruption injects large amounts of ash and sulphur aerosols into the stratosphere and upper troposphere. In addition to causing rare atmospheric optical effects—a bluish tint to the Sun and Moon, a milky cast in the daylight sky, and lurid sunsets[1,2]—such events can have pronounced effects on weather and climate that may persist for several years. Current interest[3,4] in the climatic effects of volcanic dust and aerosols has been heightened by a series of eruptions of the Mexican volcano El Chichón in 1982 and the eruption of Mt St Helens. A new dimension has been added by the recent development of proxy records of past eruptions from measurements of acidity, chemical impurities and microparticle content of ice cores from the polar regions[5–7]. We propose here that the occurrence of frost-damage zones in accurately dated tree-ring sequences from subalpine bristlecone pines in the western USA is closely linked to climatological effects of major volcanogenic atmospheric veils, and that these frost rings represent new, independent proxy records of climatically effective eruptions during the past several thousand years.

Frost rings and meteorological events

Frost damage to the wood of mature trees is a rare phenomenon caused by temperatures well below freezing at some time during the growing season, when secondary wall thickening and lignification of immature xylem cells in the annual ring is not yet complete. Freezing promotes extracellular ice formation and dehydration which result in crushing of the outermost zone of weaker cells, leaving a permanent, anatomically distinctive record in the wood[8]. Two successive nights with temperatures reaching −5 °C and an intervening day at about the freezing level are sufficient to cause frost damage[9]. Two types of frost rings can be distinguished: earlywood frost damage in the inner part of the ring, which occurs near the beginning of the growing season and latewood frost damage, which typically involves only the dark zone of small, thick-walled cells formed near the end of the growing season (Fig. 1). If the period of cambial activity is known, observing the position of the damage in a ring often permits dating of the event to within a week or two. If daily meteorological data are available, it is usually possible to identify the specific date on which the damage took place and thus, to characterize the synoptic meteorological situation as well as the antecedent climatic conditions that may have contributed to formation of a frost ring.

Frost-damage zones have been produced in the annual rings of subalpine bristlecone pines (*Pinus longaeva* D. K. Bailey and *P. aristata* Engel.) at intervals of a few decades to a few hundred years for at least the past 4,000 yr. They are observed at localities ranging from California to Colorado, a distance of some 1,300 km. In the course of tree-ring chronology development, the presence and type of frost damage in dated annual rings from living trees[10–12] and sub-fossil wood[13,14] was routinely noted. It soon became clear that frost damage had not occurred randomly, but that characteristic frost-ring dates were common to many trees at the same site or general locality, and even to localities several hundred kilometres apart. For the period of meteorological record it was possible to identify the dates of damaging related meteorological events because the growing season of bristlecone pine is known fairly well. For example[15,16], in the White Mountains, California and the Snake Range, Nevada the frost event that produced latewood damage in AD 1884 (Fig. 1) probably took place on 9–10 September, and similar latewood damage in 1965 probably occurred on 17–19 September. In each case temperatures reached new record lows for the month at nearby meteorological stations. In 1902 an earlywood event recorded in the Snake range almost certainly occurred on 3–4 July when the minimum temperature at upper treeline is estimated to have been −10 °C or below. There is clearly a relationship between such unusual meteorological events and the formation of frost rings in subalpine bristlecone pines.

Antecedent climatic conditions may also be important. Study

of two years (1884 and 1965) in which latewood frost damage took place in bristlecone pines in California and Nevada shows that these were notably cool summers in the western Great Basin[17,18]. One effect of such cool conditions is to delay both the onset and the completion of cambial activity. Bristlecone pines near upper treeline normally begin radial growth about late June, and cell maturation is complete by late August, some 3–4 weeks later than in trees near the lower forest border in the same area[19]. During a cool summer, maturation may be delayed to late September, when severely cold weather would be more likely to occur even during a normal year, and this would widen the tree's 'window of vulnerability' to damaging frost.

Climatic effects of eruptions

One important consequence of a large explosive eruption is the spread of a stratospheric veil of fine silicate ash and sulphur aerosols, with resultant surface cooling[20] that may be accentuated at high latitudes by the veil's long residence time in the Arctic stratosphere[21,22]. The degree of concentration of such a

Notable frost rings are those occurring at two or more localities or in 50% or more of sampled trees in any one locality (years of occurrence in both Great Basin and Rocky Mountains are underlined). Period analysed is AD 560–1969. Major volcanic events are individual eruptions or closely spaced eruption sequences (bracketed) having a combined Dust Veil Index (DVI/E_{max}) estimated by Lamb[1] as 1,000 or more. Period analysed for volcanic events is AD 1500–1968.

* Earlywood.

† Estimated aerosol injection has been revised upward[23,27,28].

cooling effect, and the time lag involved depends in part on the location of the volcano and the composition of the veil[23], on the prevailing circulation, and in part on the season of the year in which the eruption occurs[1].

The effects of an aerosol veil on the large-scale atmospheric circulation have been studied by empirical methods and by modelling. Early work by Wexler[24] on the 700 mbar pattern to be expected following a major eruption suggested that a probable circulation response would be expansion of the circumpolar vortex and intensification of an upper level trough over western North America in January. He proposed a summer pattern of westerlies displaced south of normal, and unseasonable synoptic conditions, such that the July weather chart would resemble that of a normal mid-May. Wexler's basic premise seems to be supported by Lamb's observation[21] of southward displacement of the sub-polar low-pressure zone in the North Atlantic sector in the first July following a great eruption, and continuing in some cases for 3–4 yr. Flohn[25] has speculated that one effect of the intensified polar cold vortices expected to result from high-latitude cooling associated with a stratospheric veil is increased meridionalization of the mid-latitude westerlies. Such quasi-stationary, meridional flow patterns are "... characterized by large-scale standing eddies, extending with diagonal troughs near 200 mbar far into the tropics, and leading to an increased frequency of extreme and unusual weather situations..." Modelling results seem to support the general kind of circulation changes proposed by Wexler, Flohn, and others as consequences of a volcanic aerosol veil. Hunt[26], in an early attempt, incorporated volcanic debris in an experiment using a three-dimensional, multilevel general circulation model with a dynamic dust veil of Krakatoa's magnitude. In the short term, he found an overall decrease in zonal wind intensity and changes in the intensity of

the mean meridional cells, coupled with a decrease in mean hemispheric surface temperature. Cool summers that may contribute to occurrence of frost rings in the western USA seem to be characterized by such increased meridionality, with frequent development of a deep trough at the 700-mbar level in the middle troposphere[10]. Individual spring, summer, and autumn months can be 2–4 °C cooler than normal under this synoptic regime. Bearing in mind that the climatic impact of any individual veil will be tempered by such factors as the preeruption state of the Earth–atmosphere system and the location of the volcano, we suggest that the anomalous circulation over western North America in years following great eruptions could consist of southerly displacement of the general westerly flow and/or more frequent development of an upper level trough, accompanied by occasional outbreaks of unseasonably cold air from higher latitudes. Synoptic situations more typical of winter may be expected to occur in late spring and in early autumn. Such a scenario seems to have been followed in the frost-ring year of 1884, where an examination of daily surface-pressure maps for 9 and 10 September shows a very large high-pressure area extending from northern Saskatchewan and Manitoba down through California, Nevada and Utah, probably representing an outbreak of cold Arctic air that took place unusually early, near the end of an already cool and delayed growing season. The mid-May snowstorm and late September cold-wave in 1983 in the Rocky Mountains and High Plains of the western USA could be more recent examples.

Frost-ring records

Data from bristlecone pines at seven localities in the western USA[12] were studied in this work (Fig. 2). These include three sites in New Mexico and southern Colorado, two sites in the Colorado Front Range, one site on the Nevada-Utah border, and four sites in the White Mountains of eastern California. The tree-ring records from the Rocky Mountains begin between AD 560 and 1535. The chronology from the central Great Basin begins in AD 737. Although all of the sites have potential for chronology extension based on records from dead trees and remnants, this approach has been most successful at one site (Campito Mountain) in the White Mountains, where the continuous upper treeline chronology begins in 3435 BC [11,13,16]. The chronological control provided by these cross-dated tree-ring records representing large numbers of trees ensures accurate placement in time of both the frost-damage event and any associated volcanic eruptions.

Frost rings vary considerably from one event to another in the severity of cell damage, in their frequency of occurrence at a particular site, and in their range of distribution. Branches, seedlings, and very young trees also show a high incidence of frost damage[15], but the results discussed here are based on fairly homogeneous samples of old, well-established trees. With few exceptions, such as 1902, earlywood damage in a given year is restricted to a single locality, perhaps reflecting a local meteorological event or indicating that only at this locality had the trees begun cambial activity, rendering them susceptible to frost damage. However, latewood frost damage is frequently found to have occurred at several localities in the same year, even where these are separated by hundreds of kilometres. For example, several frost events are common to the Rocky Mountains and to the Snake Range, others to the Snake Range and the White Mountains. These variations in severity and geographical extent of latewood damage provided us with a basis for the stratification of frost-ring years that we have used to identify the more important occurrences, termed 'notable frost-ring events'. The results for all of the western USA for the period represented by chronologies from two or more localities are given in Table 1. There are 25 of these notable events in a total of some 116 individual years during which frost damage occurred in at least one sampled tree somewhere in the region. A similar stratification based on less stringent criteria was used for the White Mountains record alone, covering the much longer period 3435 BC to AD 1971.

Krakatoa effect

The postulated linkage between atmospheric veil effects caused by major volcanic eruptions and the climatological and meteorological setting for severe and widespread frost damage was originally suggested by the remarkable coincidence of frost-ring dates which fell no more than 2 yr after each of the four climatically effective Northern Hemisphere or equatorial eruptions and eruption sequences of the past 100 yr. These dates are 1884 (Krakatoa, 1883), 1902 (Pelée, Soufrière, early 1902), 1912 (Katmai (Novarupta), early 1912), and 1965 (Agung, 1963). In addition to their measured effects on the intensity of the direct solar beam[21], the aerosol veils associated with most of these eruptions seem to have caused widespread surface cooling[20,23]. To provide a much longer, if less accurate data set for further evaluation, we referred to Lamb's volcanic eruption chronology[1] and to his dust-veil estimates. A better eruption catalogue is now available[28], which is longer, more complete, and probably more objective than Lamb's in its assessment of relative magnitudes, because it incorporates the Volcanic Explosivity Index (VEI) of Newhall and Self[29], which emphasizes the explosive eruptions that are most effective in injecting gas and ash into the stratosphere. However, this index does not weight eruptions by geographical location to provide a scaling of probable climatic impact, so we chose to use Lamb's geographically weighted Dust Veil Index (DVI/E_{max}) in this initial comparison. We identified as 'major volcanic events' those eruptions and/or closely spaced eruption sequences, for which Lamb had assigned DVIs of 1,000 or more. For reference purposes, note that Lamb had scaled his indices to give Krakatoa, 1883, an index of 1,000. There are 19 such events in the total period, AD 1500–1968, covered by his chronology (Table 1 and Fig. 3). In 10 cases, a notable frost event as previously defined occurred in the western USA in the same year or within 1 or 2 yr following a major eruption or eruption sequence. It is also true that in nine cases a frost event occurred without an apparent antecedent volcanic event, and seven volcanic events have no known associated frost event.

To test the statistical significance of this apparent relationship, we separated the total period of concurrent frost and volcanic events into two parts. That period from 1882 to 1968 includes the four well-documented volcanic events cited above and, moreover, is a period for which meteorological data are adequate to characterize climatically-effective eruptions through their depression of hemispheric temperatures as well as to study associated regional climatic and meteorological anomalies. Our approach was to divide the 87-yr period into 29 discrete 3-yr intervals (2–3 yr is a typical decay period for stratospheric aerosol veils[20]), or triads, and then to count the number of cases in which a notable frost event occurred in the same triad as a major volcanic event. The starting date of 1882 was chosen so that 1883–84 and 1963–65 would be respectively grouped in the same 3-yr intervals, and so that the last year of Lamb's chronology would be included. From elementary probability theory[30], the expected frequency of joint occurrences of events in two random, completely independent series is equal to the product of their individual probabilities. Thus, if we assume that these probabilities are equal to the observed average frequencies, we would expect such joint occurrences to take place with a frequency of only 0.024, less than one time in 29 triads (Table 2). The observed number is nearly six times that expected by chance (note here that neither in this nor in the following analysis does the frost-ring date precede that of the associated volcanic eruption within a triad). A similar analysis was performed for AD 1500–1880 that included 127 triads and six joint occurrences. The observed number is over four times the expected chance value. The final step in our evaluation was a contingency analysis using the χ^2 statistic calculated from the observed and expected frequencies of joint occurrence[31].

Despite the small sample size, the results suggest that for each subperiod, the observed number of joint occurrences of volcanic and frost events is very unlikely to have arisen by chance. Therefore, we can reject the null hypothesis of random association, and accept the alternative hypothesis—that major eruptions are likely to be closely followed by notable frost events—at better than the 99.9% confidence level.

The analytical results show that we can tentatively associate many notable frost events in the western USA over the past several hundred years with antecedent volcanic eruptions catalogued by Lamb. As shown in Table 3 there are other records that can be used to extend this comparison qualitatively much farther into the past, using the long tree-ring record of frost events from the White Mountains, California. However, because it is based largely on data from a single tree-ring site, this frost-event chronology offers a less complete basis for comparison with volcanic events than does the broadly based regional data set given in Table 1. There are also greater uncertainties in the volcanological records in the earlier time periods. We have used the eruption catalogue of Simkin *et al.*[28], which is much longer than Lamb's. The initial Greenland ice core data[5] also provide a long, but locally biased and perhaps less well dated and possibly less complete eruption record spanning the past several thousand years, based on acidity peaks attributed to volcanogenic aerosols. Finally, we have referred to well-dated eruptions in the late BC-early AD period that are based on careful evaluation[2] of historical and archaeological records of volcanism and atmospheric veils in the Mediterranean region.

The apparent correspondence of frost events and eruptions is not as good as in the more recent past, but some coincidences are worth noting. Severe frost damage occurred in AD 1601, and may be linked to the acidity peak described[5] as one of the strongest of the earlier signals in the Greenland ice record. The ice-core data do not reflect a peak at the time of the 1500 frost ring, but an eruption occurred that produced atmospheric optical effects in Europe and is reported by Lamb to have taken place in Java[1]. A large eruption of Mt St Helens also occurred about this time[28]. The severe frost event of 1453 could be linked to a low acidity peak about 1453[5], possibly related to a large eruption of Kelud in 1451[28]. The high acidity peak[5] at about 1258 is not represented in the frost record and, there seem to have been no great eruptions that might account for the numerous frost events from 687 to 1200. However, another strong signal in the Greenland ice is dated at about 623 and may reflect the eruption whose atmospheric veil was recorded in Europe in 626[2] and which might be related to the 628 frost event. The volcano is unknown, but could be Rabaul, in New Britain[28]. There is no documentary record of an atmospheric veil at the time of the frost event in 601, and no corresponding acidity peak. However, a major eruption took place in the White River field, Alaska, at about that time[28].

Referring to the earliest part of our record, only four notable frost-damage events are recognized in the White Mountains in the 4036-yr period before AD 601. One of these events, in AD 119, falls in a gap between the Crête and Camp Century ice records, but could be related to a major eruption of Ilopango, El Salvador, in the Second or Third Centuries[28]. Another, dated to 42 BC, might correspond to one of three peaks in the Camp Century core, approximately dated to 260, 210, and 50 BC, respectively[5]. It follows closely the great eruption of Etna, well dated to 44 BC from direct observations[2]. A third frost event, in 2035 BC, is the most severe in the entire record, as it occurs in all the trees in the sample and caused severe anatomical damage[16]. There does not appear to be a corresponding acidity

Table 2 Basic data and results of contingency analysis of frost-ring occurrence following major eruptions, AD 1500–1968

Period	1882–1968	1500–1880

Notable frost rings occur at two or more sites, or in 20% or more of trees (years of occurrence in 50% or more of trees on any site are underlined). Period analysed is 3435 BC to AD 1971. Northern Hemisphere and equatorial eruptions were listed if they have a Volcanic Explosivity Index (VEI[29]) of 5 or greater[28], or were represented by ice core acidity peaks[5] or well documented atmospheric veils[1,2]. Source 1 covers the period from AD 1500; 2 from 700 BC to AD 630.
* Earlywood.

peak in Greenland, but the frost-ring date coincides approximately with a large radiocarbon-dated eruption of Mt St Helens[28].

Santorini connection

The remaining frost event in the BC–early AD time period, dated to 1626 BC, is especially notable, not only for its severity, but because it offers the intriguing possibility of dating precisely the cataclysmic eruption on Santorini (Thera) in the Aegean Sea in the second millennium BC. The frost-ring date had seemed to place the eruption too early in time to match the conventionally accepted date of 1500–1450 BC based on the archaeological evidence available in the early 1970s[32], but this discrepancy in dates may now be resolved.

Because the volume of ejecta has been estimated at several times that of Krakatoa, the Santorini eruption seems likely to have produced a major, climatically effective aerosol veil, which is also likely, on present evidence, to have been linked with a notable frost-ring event. Betancourt and Weinstein[33] have carefully reviewed both the archaeological and radiocarbon evidence for the dating of the beginning of the late Bronze Age in the Aegean. In particular, they focus on radiocarbon dates from material obtained during the excavation of a late Minoan settlement near the village of Akrotiri. It lies on the south side of the largest remnant of the original volcanic island, most of which was either ejected or collapsed into the central caldera following the eruption. The excavations were begun by Marinatos in 1967, and the evidence indicates that the buildings were first toppled by earthquake, and soon thereafter buried under many metres of volcanic ash from the eruption. Betancourt and Weinstein evaluate two sets of dates associated with the destruction of ancient Akrotiri, after first calibrating or correcting the raw dates for atmospheric radiocarbon variability, using the 1973 MASCA tables. [For a fuller documentation and a discussion of these samples see Michael[34], who supported the seventeenth century BC eruption date.] The first set of dates is from 'long-lived' material, mostly wood from olive, pine, and cedar that would be expected to predate the eruption considerably; the dates are older than 1700 BC. More relevant here are the dates on six short-lived samples, including charred seeds of legumes from a storage jar, and charred fragments of shrubs. The average date given for these samples is 1688 BC ± 57 yr. More recently, four additional dates have been reported on grain from storage jars from the destruction level[35]. They have a large range, but yield an average date of 1675 BC. Given the uncertainties in the individual radiocarbon determinations coupled with the uncertainty in the calibrations themselves, our proposed eruption date of 1626 BC or perhaps 1 or 2 yr earlier, derived from frost-ring evidence, falls well within the probable range for the true date of the eruption based on radiocarbon.

Conclusions

The potential importance of frost rings as proxy indicators of past eruptions warrants careful weighing of the physical evidence and of the strength of the postulated linkage between aerosol veils, the response of the circulation, and their relation to the climate and weather of the study region. The tree-ring data base is adequate for the past several hundred years, but frost events may be greatly under-represented before about AD 600, because of the decreasing size and geographical extent of the sample. Our method of stratifying 'notable' frost events seems valid, but the summing of magnitudes of closely spaced eruptions (Table 1) may not be justifiable physically in all cases[20]. The comparison of dates of eruptions and frost rings shows that there is not a one-to-one correspondence. Frost events that are unrelated to aerosol veils have occurred, for example, in 1941. Conversely, there were notable eruptions with no associated frost ring in the western USA. That is, some eruptions may result in a frost record at a certain locality while others may not, and frost damage can be due to atmospheric variability from other causes. We also emphasize that comparisons of the kind that we have attempted become increasingly unreliable in the earlier part of the record. This is due partly to uneven reportage of eruptions and partly to the uncertainties in dating of geological, archaeological, glaciological and other sources of evidence.

Further testing of our hypothesis might include the analysis of an improved frost-event chronology for the western USA using an expanded tree-ring data base. Because frost rings are found in trees in the sub-Arctic and in the high mountains of lower latitudes in many parts of the world[36–40], other frost-event records from suitable regions could be compared independently with volcanic chronologies. Our preliminary findings also suggest the need for empirical studies of regional climatic variability and analysis of modelling results to see how important volcanogenic aerosol veils may be as a causal factor in frost-ring formation.

We thank the NSF for financial support of much of the original work on which this research is based, J. M. Mitchell and H. Flohn for stimulating discussions on aerosol veil climatology and P. I. Kuniholm for an introduction to the fascinating but often vexing problems of the late Bronze Age in the Aegean and V. A. S. McCord and A. Allen for help in preparation of the manuscript. We thank W. J. Robinson for permission to reproduce Fig. 2, which originally appeared in the *Tree-Ring Bulletin.*

DNA sequence of the maize transposable element *Dissociation*

H. P. Döring, E. Tillmann & P. Starlinger

Institut für Genetik, Universität Köln, 5000 Köln 41, FRG

The DNA sequence of the terminal 4.2 kilobases (kb) of the 30-kb insertion in the endosperm sucrose synthase gene of maize mutant sh-m5933 shows that it comprises two identical 2,040-base pair (bp) segments, one inserted in the reverse direction into the other. We suggest that the 2,040-bp sequence is an example of the transposable element Dissociation *described by Barbara McClintock.*

TRANSPOSABLE elements were first detected and characterized in considerable detail by McClintock[1,2]. Nearly 20 years later, similar elements were studied at the DNA level first in bacteria[3–5] and later in a variety of eukaryotic organisms, notably *Drosophila melanogaster* and *Saccharomyces cerevisiae*[6,7]. The structure of these latter elements has been elucidated rapidly, including their complete DNA sequences. It would be desirable to study isolated maize transposable elements because of the variety of genetic phenomena associated with them[1,2,8]. Even when such elements are inserted at the same gene locus, the resulting phenotypes can be quite different. Sometimes, the phenotype resulting from a particular element remaining at the same site is variable in a clonally heritable way ('change in state')[9,10]. It would be interesting to study the structural correlate of these functional changes. DNA probes derived from the transposable elements might be used to isolate genes previously tagged by the insertion of the element. Eventually, the elements might be used as a vector for the introduction of new genes into chromosomes, as has been demonstrated first in bacteria[11,12] and recently in *Drosophila*[13,14].

As no gene products of transposable elements in plants are known, conventional means of isolating these elements cannot be used. It is possible, however, to isolate DNA clones of genes that have previously been mutated by the insertion of a particular transposable element. Isolation of DNA from wild type and mutant genes reveals the presence of DNA foreign to the gene in question, which can then be identified as the DNA of the transposable element[15]. The first plant gene to be used in this way was that coding for endosperm sucrose synthase at the *Shrunken* locus[16]. Mutants were available that were caused by the insertion of the transposable element *Dissociation* (*Ds*)[17,18]. This element cannot transpose by itself, but it can be transposed in the presence of an additional, transposable element called *Activator* (*Ac*) which acts in *trans* on *Ds*[2]. On isolation of genomic clones from *Sh*[19,20], two *Ds*-caused mutations were found (ref. 20 and E. Weck, U. Courage-Tebbe, H.-P.D. and P.S., in preparation).

In one of these mutants, *sh-m5933*, the mutation was shown to be due to a complicated event, leading to the insertion of a 30-kilobase (kb) DNA segment, and a duplication of part of this genetic region was found[21]. The DNA contained in the clone was characterized by restriction analysis, and the DNA adjacent to the cloned segment was studied by Southern blot analysis. From these studies, we hypothesized that only the parts of the insertion located at both of its junctions with *Shrunken* DNA, are transposable elements. The DNA located between the two regions of transposable elements is of unknown origin; part of it is unique, other sequences comprise repeated DNA[20] (K. Theres, unpublished observations). To test this hypothesis, we sequenced 4.2 kb of DNA adjacent to the 3′ end of the *Shrunken* gene. We show here that this sequence corresponds to two identical copies of a 2-kb segment of DNA. One of these segments is inserted in the reverse direction into the other. We discuss evidence that these 2-kb DNA segments correspond to the genetically defined transposable element *Ds* described by McClintock[1,2].

Transposable element insertion

The first 4.2 kb adjacent to the junction between the 3′ end of the *Shrunken* gene and the large insertion mentioned above were sequenced. Figure 1 shows the sequencing scheme and the sequence itself is given in Fig. 2. The 4.2 kb sequence is made up of two identical sequences of 2,040 bp. These sequences are found, however, in an unusual arrangement, one being inserted into the other. The two sequences are inverted with respect to each other (see Fig. 3).

We have reported previously that two pairs of inverted sequences are present near the junction between wild type sequences and the insert[20]. The DNA sequence analysis presented here shows that this really is the case, and also shows that the two pairs of inverted repeats described previously[20] are adjacent to each other.

We can ask whether the two 2-kb sequences are transposable elements, and whether the 4-kb structure has been formed by the insertion of one such element into a copy of itself. Many transposable elements terminate in inverted repeats, and almost all of them are flanked by short direct repeats of the recipient sequence. If these structures are found at the termini of a DNA sequence, this sequence may be a transposable element. Figure 2 shows that by these criteria, the 2-kb sequence described above may be a transposable element; both the inserted and the recipient copy of this sequence terminate in an 11-bp inverted repeat. Thus, this 11-bp sequence is found four times, the two right-hand and the two left-hand ones being oriented in the same direction with respect to each other (Fig. 3).

The internal 11-bp inverted repeats are flanked by 8-bp direct repeats. If these are the result of insertion of one copy of the 2-kb element into the other, the 8-bp sequence should be found only once in the internal copy of the transposable element. This is borne out by the sequence. No 8-bp duplication flanks the recipient 2-kb structure. We expect that the 8 bp of *Sh* DNA bordering the inserted DNA at the 3′ junction will be repeated at the 5′ junction of the 30-kb insert. However, this has not yet been cloned. We conclude, therefore, that the 2-kb sequence is indeed a transposable element and that the more complicated 4-kb structure was created by the insertion of one copy of this element, in inverted orientation, into the other one. We will show below that this transposable element is an example of McClintock's *Ds* and we will refer to the structure described here as a double-*Ds*, or *D*(*s*′*D*′)*s*.

Relationship to *Dissociation* elements?

It is conceivable that the large, ~30-kb insertion in *sh-m5933* is in fact *Ds*. We argue here, however, that the small, ~2-kb

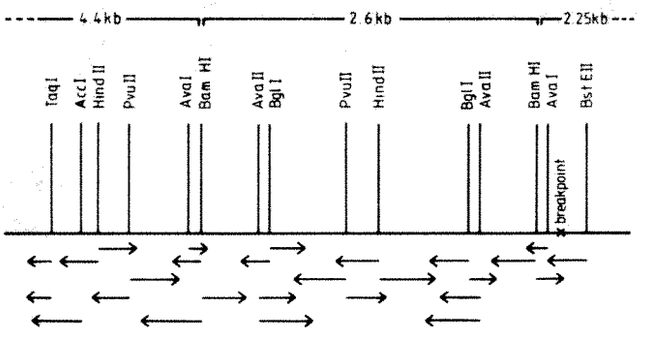

Fig. 1 Sequencing strategy. All sequences were determined (usually twice) by 5′ end labelling and chemical degradation according to Maxam and Gilbert[32]. The arrows indicate the sites of labelling and the extent of sequence read.

structure is *Ds* and that the large insertion in *sh-m5933* consists of several copies of *Ds* and some unique DNA not belonging to this transposable element. Such a conclusion cannot be drawn from the sequence analysis of one element alone; our structure must be compared with other mutations caused by the integration of *Ds*. However, we present the following evidence:

(1) We have isolated a null mutation, *adh1-2F11*, in the gene *Adh1* which encodes alcohol dehydrogenase[22]. Genetically, this mutation is caused by *Ds*, because it is unstable in the presence of *Ac*, while no reversion to the wild type phenotype is observed in the absence of *Ac*. DNA blotting experiments show the presence of a 1.3-kb insertion in the gene. RNA blotting experiments show an increase in the RNA size corresponding to the insert size within the gene. The enlarged RNA hybridizes to a probe derived from the 4-kb sequence described above, while the wild type RNA does not, indicating that the two inserts in the genes *Sh* and *Adh1* have some DNA sequences in common.

(2) Another mutation, *Adh1-Fm335*, was isolated previously by Osterman and Schwartz[23]. By genetic criteria, the mutation is caused by insertion of *Ds*. Peacock and collaborators have sequenced the wild type, mutant and revertant genes[24,25], and found that the mutation is caused by the insertion of a 405-bp DNA segment. The 11 nucleotides at the termini are inverted repeats. The sequence found at the termini of the 2-kb transposable element in *sh-m5933* is identical to the inverted repeat first described by Peacock *et al.*[24] in the *Adh1 Ds* insertion. The insertion in *Adh1* is also flanked by a direct repeat of 8 bp. These findings argue that different copies of *Ds* terminate in the same 11-bp repeat and generate 8-bp duplications of the recipient sequence on insertion. Analysis of revertants at the *Adh1* locus[24] has demonstrated that the 405-bp insert bounded by 11-bp inverted repeats is a *Ds* element, supporting our contention that the 2-kb structure which we have described is also a *Ds* element, that the inverted 11-bp sequence may be sufficient for transposition by an *Ac*-encoded function of a DNA sequence bracketed by these inverted repeats, and that more complicated structures can be built from the simple unit *Ds*.

(3) Another *Ds*-induced mutation at the *Shrunken* locus, *sh-m6233*, has been analysed by the blotting technique[20]. A genomic DNA clone containing one terminus of the insertion and adjacent DNA of the *sh* locus has been isolated and the junction sequenced (E. Weck, U. Courage-Tebbe, H.-P.D. and P.S., in preparation). The first 70 nucleotides adjacent to the junction including the 11 nucleotides at the junction, are identical to the sequence of the 2-kb transposable element found in *sh-m5933*.

These biochemical findings are strongly supported by the genetic observation that excision of the 30-kb structure inserted in *sh-m5933* and reversion to the *Shrunken* wild type occurs only in the presence of *Ac*[21]. Thus, the mobile transposable element-like structure ending in 11-bp termini is probably an example of *Ds*.

Length variation of *Dissociation* elements

From the above, it is clear that *Ds* isolates can differ in length. The *Ds1* of *adh Fm335* sequenced by Peacock *et al.*[24] is only 405 bp long, while our unit *Ds* is 2 kb long. The *Ds* in *adh1-2F11* has an intermediate length of ~1.3 kb. Fedoroff *et al.*[26] found a *Ds* in a clone of the gene *Waxy* isolated from mutant *wx-m6*, which closely resembles our 2-kb *Ds* by restriction mapping. The finding of *Ds* isolates of different length and the observation that *Ds* is deficient in several functions such as excision from a gene locus, transposition and production of chromosome breaks at the site of insertion, but that it can be complemented *in trans* by *Ac* suggests a hypothesis for the origin of different *Ds* copies[8]. It is conceivable that these arise from *Ac* by internal deletions which both reduce the length and abolish the function. Fedoroff *et al.*[26] have isolated *Ac* from another *Waxy* mutant, *wx-m9*, and found that it is ~4.2 kb long. Heteroduplex analysis and restriction mapping has shown that *Ds6* of *wx-m6*, is an internal deletion of *Ac* of *wx-m9*.

Comparison of the *Ds* sequenced by Peacock *et al.*[24,25] and *Ds5933* shows that the situation may be more complex. Apart from the 11-bp repeats at the termini, there is little sequence similarity. Thus, *Ds* can either be formed from *Ac* by a multi-step event, or there exist different families of *Ac* and *Ds*[27].

Evolution of double *Ds*

The creation of independent *Ds* copies by deletions from *Ac* has been discussed above. Another possible means of evolution of different *Ds* structures is evident from the structure of the double *Ds* at the 3′ junction in *sh-m5933*. From Fig. 3 it is apparent that different structures bordered by two inverted repeats of 11 bp could be transposed from the double *Ds* (these are indicated by brackets). The data obtained by DNA blotting analysis of the inserted DNA adjacent to the 5′ junction in *sh-m5933* are compatible with this assumption[21]. The restriction pattern of the mutant and of several of its revertants is most easily explained if the sequence located at the 5′ junction of *Shrunken* and *Ds* DNA is an inverted copy of part of the double *Ds* at the 3′ junction (indicated by the bracket marked II in Fig. 3). If this interpretation is correct, the structure at the 5′ junction of the insertion consists of 1.5 copies of the 2-kb *Ds*. Part of the 2-kb sequence is present only once at the 5′ junction, while the other part is present twice (Fig. 3).

The deletion of part of the structure in one of the revertants, *sh-r5*, and the restriction pattern of the non-deleted part are compatible with the assumption that a unit *Ds* has been excised (Fig. 3). We assume that the remaining half *Ds* element carries the characteristic 11-bp sequence at one terminus only. This will have to be checked by cloning and sequencing. We anticipate that this structure can no longer be excised. However, chromosome breaks at this site are still detected[21]. It is possible that the occurrence of such breaks is not dependent on the presence of the 11-bp sequence at both termini.

Other sequence features of *Ds*

The sequence described here has a few peculiarities, including similarities to other transposable elements, direct or inverted short duplications and insertion sites, repeated oligonucleotides within *Ds* as well as an open reading frame. In none of these cases is a functional significance known.

Termini of *Ds*: Several transposable elements have the dinucleotide TG at the 5′ terminus of their long terminal repeat. In some of the retroviruses, the characteristic TG is preceded by the dinucleotide AA[28]. The hexanucleotide ATGAAA is shared between the termini of the murine leukaemia and sarcoma viruses and *Ds*. In the case of *Ds*, this represents the inner hexanucleotide of the characteristic terminal 11-bp sequence.

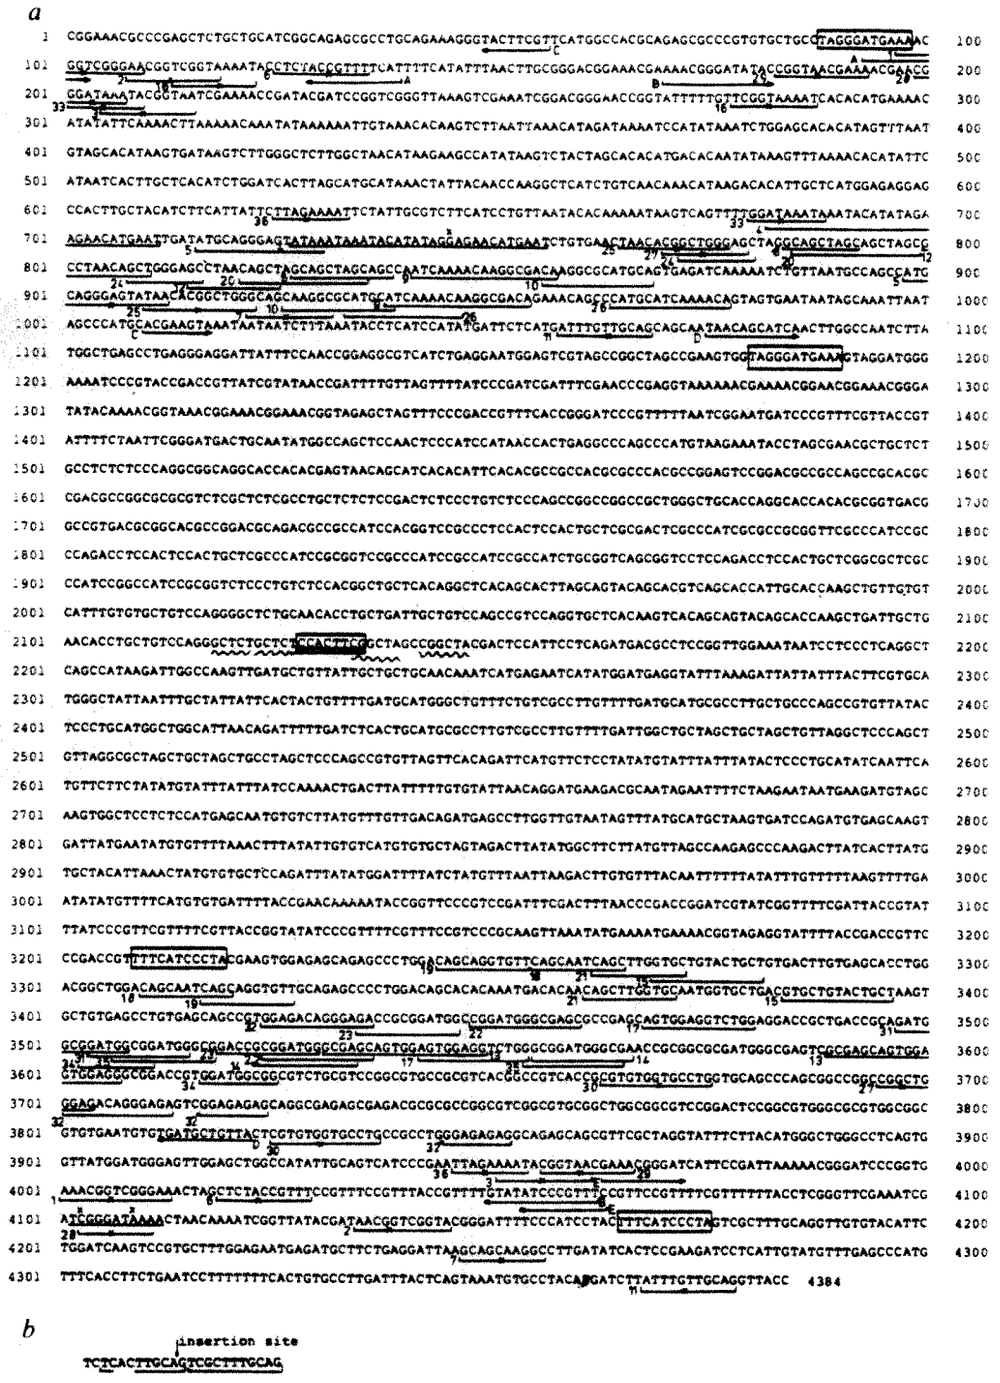

Fig. 2 *a*, Sequence of double *Ds* from *sh-m5933*. The sequence of the transposable element-like structure starts at position 88 and ends at position 4,175. The sequence adjacent to these termini is an 8-bp direct repeat, CGAAGTGG, which is found only once at position 2,128–2,135. The 11-bp inverted repeats and the internal 8-bp insertion site are boxed. The direct repeats (numbered) and the inverted repeats (lettered arrows) are indicated by underlining the outer sequence only. The region between positions 3,960 and 4,080 contains eight copies of CCGTTT, four copies of AAACGG and several near relatives of this sequence. The outer and the inner sequence of *Ds* are identical except for the 8-bp duplication in the outer sequence flanking the insertion of the inner one. At position 955 an ambiguity exists, due to differences in reading the sequencing gels of the opposite strands. Between positions 955 and 956, a C may have to be inserted. The same is true between positions 2,351 and 2,352, where a G might have to be inserted. *b*, Insertion site of *Ds* in *sh-m5933*.

The three adenine residues at the end of the sequence form part of a pentanucleotide AAAGA which is also found at the terminus of the FB transposon in *Drosophila*[29]. Another similarity between *FB* and *Ds* will be described below. Similarities between the termini of the maize transposon *Cin1* and the *Drosophila* transposon *copia* have been described by Saedler *et al.*[30]. In this case, the first pentanucleotide was shared between the two transposons.

Many transposable DNA elements terminate in inverted repeats which can be mismatched. We have screened the sequence inwards from the 11-bp terminal inverted sequences, and have found two penta- and one hexanucleotide on one side which are found in inverted orientation near the other terminus, and which are separated from each other by no more than 10 bp. We have also observed a perfect 11-bp repeat on the left-hand side of *Ds* near one end, at positions 93–103 and 129–139. Near the right-hand end of *Ds* we find a mismatched inverted repeat at positions 4,102–4,112 and 4,165–4,175. These two inverted repeats provide pairing capabilities alternative to that between the two opposite ends of the *Ds* elements.

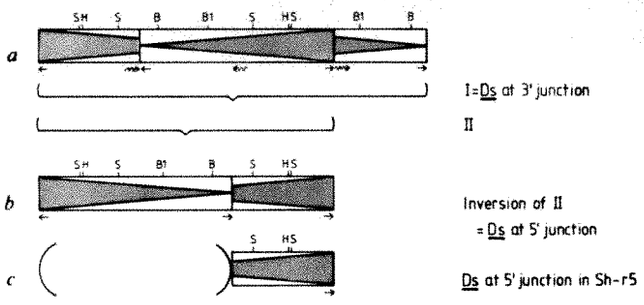

Fig. 3 Schematic representation of double *Ds* and derivatives of it. *a*, Double *Ds* at the 3′ junction of *sh-m5933*, as sequenced by us. The solid arrows below the figure indicate the 11-bp inverted repeats (not to scale). The wavy arrows indicate the 8-bp duplication. The brackets indicate two different structures that can presumably be transposed. *b*, Hypothetical structure of *Ds* at the 5′ junction of *sh-m5933* both in the complete gene and in the duplication, as derived from restriction mapping on the assumption that structures having 11-bp inverted repeats at their termini can be transposed. *c*, Hypothetical structure of *Ds* at the 5′ junction in the duplication of revertant *sh-r5*. This structure is deduced from restriction mapping, which shows a decrease in fragment size for several restriction enzymes cleaving outside *Ds* and a smaller decrease of an *Sph*I fragment which is in accord with the map given here. (B = *Bam*HI, S = *Sph*I, B1 = *Bgl*I, H = *Hin*dII.)

Insertion sites: In *sh-m5933* there are two *Ds* insertion sites, one located near the centre of *Ds*, where one *Ds* copy is inserted into the other one, the other localized in the sucrose synthase gene, where the 30-kb sequence is inserted. Both of the insertion sites are characterized by short sequence duplications. These are present before the insertion and must not be confused with the 8-bp duplications created by the insertion. In the case of the insertion in the sucrose synthase gene, the duplication is 11 bp long, with one mismatch and one base deletion. The insertion site of *Ds* into *Ds* is characterized by the presence of one hexanucleotide and one pentanucleotide as direct repeats. In both cases, the insertion site is located in one of the duplicated oligonucleotides (see Fig. 2*a*, wavy lines, and Fig. 2*b*).

Direct and inverted repeats: The *Ds* sequence is characterized by the presence of many direct and several inverted repeats of variable length. The perfect repeats exceeding 8 bp are indicated in Fig. 2 by underlining. There are additional examples of slightly mismatched repeats which have not yet been analysed in detail.

The position of the direct repeats is non-random. Many are separated by short stretches of DNA, others are adjacent to each other. Some pairs of repeats partially overlap others. We cannot suggest a mechanism for the origin of these repeats apart from the vague notion that in some *Ac–Ds* functions replication and/or recombination events may be involved that are not encountered regularly with other DNA segments.

The repeats are found in most of the *Ds* sequence; only the regions from nucleotides 310–670 and 1,080 to 1,180 are relatively free of them. These regions do not coincide with open reading frames. The 609-bp open reading frame mentioned below is full of repeated sequences. The DNA segments containing the repeated sequences may provide an explanation for the observation that independently isolated *Ds* elements can be of different length and may be derived from *Ac* by internal deletions. Whether a sequence variability generated by recombination events in *Ds* is the basis for the known 'states' of *Ds*[2,9] may be the subject for future experiments.

Repeated hexanucleotide: Near one end of *Ds*, a region of ~230 bp is characterized by the presence of 15 copies of the hexanucleotide CCGTTT and close relatives of it, which differ from the hexanucleotide by one base substitution. Four of these hexanucleotides are oriented opposite to the others. Some of them lie adjacent to one another, while others are separated by one or a few nucleotides. A similar structure has been described for the *FB* transposon of *Drosophila*[29], in which the repeated structure is a decanucleotide. It shares the first five nucleotides, CGTTT, with our hexanucleotide, which may be coincidental. Given the increasing number of similarities between *Drosophila* and maize transposons (see above) the possibility of horizontal transmission of DNA between these two species should be considered.

Open reading frames: The only sizeable open reading frame, starting with an ATG, is located between nucleotides 3,373 and 3,981, possibly encoding a protein of 203 amino acids. The sequence around the ATG at position 3,373, GNNATGG, has been observed to be a translation start site in animals but not yet in plants[31]. We have observed no promoter-like structure preceding it. Whether this open reading frame is transcribed and/or translated is unknown.

Conclusions

The DNA sequence described here resembles other transposons in having inverted DNA repeats at its termini and in creating short direct DNA duplications at the site of insertion. The DNA sequence between the 11-bp inverted repeats does not contain long open reading frames. Whether the abundance of direct and inverted repeats in this structure has a functional significance is unknown. Rearrangements involving these sequences are conceivable and may form the basis for 'changes in state'.

The sequence dissimilarity between *Ds1*[25] and *Ds5933* described here suggests that DNA located between the 11-bp inverted repeats is transposed passively. This fact may be exploited in gene transfer experiments. The observation that sequences hybridizing to *Ds5933* are present throughout the maize genome in multiple copies[20] will make the identification of particular genes mutated by the insertion of *Ds* difficult, but not impossible. Experiments along these lines are in progress in our laboratory.

We thank K. Stüber for invaluable help in the analysis of DNA sequences and N. Fedoroff and J. Peacock for communicating unpublished results. The work was supported by Deutsche Forschungsgemeinschaft through SFB 74.

Mode of proviral activation of a putative mammary oncogene (*int*-1) on mouse chromosome 15

Most mammary carcinomas induced in C3H mice by the mouse mammary tumour virus (MMTV) bear a new proviral insertion within a highly conserved locus on chromosome 15 called int-*1. A transcriptional unit within this locus is inactive in all tested normal tissues but expressed at low levels in mammary tumours with proviral insertions positioned on either the 5′ and 3′ sides of the gene. Transcription of the proviruses proceeds away from* int-*1; thus an indirect mechanism appears to activate expression of this putative oncogene.*

THE proviruses of retroviruses can integrate at many sites in host genomes; thus, like other movable genetic elements, they act as insertion mutagens[1]. Two classes of proviral insertion mutations have been described: recessive mutations that disrupt and prevent expression of genes[2–6] and presumably dominant mutations that activate gene expression, leading to induction of tumours by retroviruses without their own oncogenes[7–13]. For example, during the induction of B-cell lymphoma by the avian leukosis virus (ALV), proviral insertion mutations augment transcription of c-*myc*, the cellular progenitor of a retroviral oncogene[7], either by provision of a retroviral promoter[7–10] or by an indirect effect on a host promoter[10].

The proposal that retroviruses lacking oncogenes induce tumours by insertion mutation of host genes suggests a strategy for the isolation of novel oncogenes. By molecular cloning of a single new mouse mammary tumour virus (MMTV) provirus from a C3H mouse mammary tumour, we have isolated a region of the mouse genome that contains an MMTV proviral insertion in the majority of C3H mammary tumours[13]. Although this region lacks homology with any of the available retroviral oncogenes, we have previously argued that it harbours an oncogene, called *int*-1, instrumental in mammary tumorigenesis because (1) MMTV proviruses can integrate at many sites in the host genome (implying that insertions near *int*-1 confer a selective growth advantage) and (2) because the insertions are accompanied by the appearance of transcriptional products from *int*-1, a silent domain in non-neoplastic mammary tissue.

We demonstrate here that insertion mutations in the *int*-1 locus usually stimulate transcriptional activity by an indirect mechanism: MMTV proviruses are located either upstream from transcribed *int*-1 sequences in the opposite orientation or downstream in the same orientation. We also assign the *int*-1 gene to mouse chromosome 15 and show that *int*-1, like the progenitors of viral oncogenes, has been conserved during evolution.

Locating and orienting MMTV proviruses

We reported previously[13] that 18 of 26 C3H mouse mammary tumours contain MMTV proviral DNA within a common region of approximately 20 kilobases (kb). The insertions are distributed with roughly equal frequency on both sides of a portion of the locus that is represented in tumour-specific, 2.6-kb polyadenylated RNA. To assess the mechanisms involved in the activation of the *int*-1 transcriptional unit, we have now determined the sites of proviral insertion more precisely and ascertained the transcriptional directions of the proviruses and the *int*-1 gene. These studies involved physical mapping of the interrupted *int*-1 loci with restriction endonucleases, using the DNA transfer method and a collection of molecular annealing reagents specific for portions of *int*-1 and for the 5′ and 3′ halves of MMTV proviral DNA. The *int*-1 probes were derived by plasmid subcloning of unique sequence DNA from recombinant λ bacteriophages containing overlapping inserts of the *int*-1 domain from a library of normal BALB/c mouse DNA. Probe C detects *int*-1 RNA in mammary tumours; probe D represents a region located leftward of probe C on the *int*-1 map as it is conventionally drawn (see Fig. 3). The probes used to orientate proviral DNA [MMTV-*env* and MMTV-*gag* (Fig. 1)] represent portions of MMTV DNA that reside near the 5′ and 3′ ends of the provirus but exclude sequences from the long terminal repeats (LTRs). In general, our strategy was to use enzymes that cleaved *int*-1 at widely separated sites and divided MMTV proviral DNA into two portions distinguishable with MMTV-*env* and MMTV-*gag* probes.

Proviruses on the 5′ side of *int*-1

Two enzymes, *Bgl*II and *Kpn*I, proved to be particularly useful for the analysis of MMTV proviruses present to the left of the *int*-1 transcriptional unit. (We will show below that transcription of *int*-1 proceeds from left to right on the physical map; thus, proviruses inserted to the left of the region represented by probe C can be considered to lie 5′ to at least a portion of the transcriptional template.) *Bgl*II cleaves the normal C3H mouse DNA at a leftward site (position −21 on the map in Fig. 3) to generate a 14-kb fragment that anneals with probe C. In addition, *Bgl*II cleaves the MMTV provirus at two sites, one of them near the middle of the element (Fig. 1). Proviral DNA in eight tumours was found to disrupt the normal 14-kb *Bgl*II fragment from one of the two *int*-1 alleles. As illustrated for six of these tumours in Fig. 1*a* and *b*, the novel fragments also annealed with the MMTV-*gag* probe, indicating that the proviruses are positioned either to the right of the probe C homology in the same transcriptional orientation as *int*-1 or to the left of the probe C region in the opposite orientation. In all eight tumours, additional mapping, illustrated here for a few tumours with *Kpn*I and probe D, showed that the latter possibility was correct (Fig. 1*c*, *d*). *Kpn*I cleaves the *int*-1 domain at the most leftward site we have mapped (position −23) and at position −11, to generate a fragment of 12 kb that hybridizes with probe D. The MMTV provirus is cut once by *Kpn*I. Novel *Kpn*I fragments annealing with probe D (Fig. 1*c*) were also detected by the MMTV-*env* probe (Fig. 1*d*), demonstrating that the proviruses are inserted upstream from the probe C homology region in orientations opposite to the transcriptional direction of *int*-1.

Thirty clones of hybrids formed by polyethylene glycol fusion of mouse spleen cells or macrophages with an established Chinese hamster cell line (380-6), deficient for hypoxanthine phosphoribosyl transferase (HPRT), were analysed for mouse *int*-1 and enzyme markers, although not all clones were analysed for every enzyme marker. Twelve of the hybrid clones were also analysed by karyotype analysis as decribed previously[22]. The symbols for the marker enzymes, their chromosome assignments and the electrophoretic procedures used to separate the Chinese hamster and mouse enzymes have been previously described[22]. In general, the presence or absence of a given mouse chromosome, as determined by karyotypic analysis, agreed with the presence or absence, respectively, of the enzyme marker for that chromosome. However, in several instances, the enzyme marker for a given chromosome was present in a clone that karyotypically lacked that mouse chromosome, indicating chromosome breakage and/or rearrangement. The presence of mouse chromosomes 3, 5, 11, 13 and Y was based on karyotype analysis alone.

Proviruses on the 3′ side of *int*-1

Similar analytical strategies were applied to DNA from 10 tumours previously shown to have insertions between positions 0 and −8 on the *int*-1 map; an 11th tumour (number 24), previously thought to lack an *int*-1 insertion, was also found to have a provirus within this region during the extended tests. Comparative annealings with *int*-1 and MMTV probes (ref. 13 and data not shown) revealed that all 11 proviruses were oriented in the same direction, with transcription proceeding from left to right on the *int*-1 map.

A particularly interesting part of this analysis, pertinent to the mechanism of expression of *int*-1, is illustrated in Fig. 2. When DNA from tumour 53 was cleaved with *Bam*HI and annealed with probe C, two novel fragments were detected in digests of each sample, indicating that the insert is positioned within the region detected by the probe. Similar results were obtained with DNA from tumour 11 (not shown). Proviruses in three other tumours (numbers 55, 12 and 15) were found to be positioned at very similar sites, about 0.6–0.8 kb to the right of the insertion site in tumour 53 (Fig. 2 and unpublished data). The inserts in these tumours lie within the transcriptional unit, and affect the size of resulting transcripts (see below).

We conclude that 19 of 26 C3H mammary tumours carry MMTV proviruses in the *int*-1 locus (Fig. 3). Eight proviruses are distributed between positions −11 and −18; each of these is oriented so that transcription of the provirus proceeds from right to left. Eleven proviruses are located within the region extending from position −8 to 0, and all are oriented so that transcription proceeds from left to right. Mapping with several endonucleases provides no evidence for deletions within either proviral DNA or *int*-1; the several atypical restriction maps of proviral DNA we encountered are best explained by restriction-site polymorphisms (data not shown).

int-1 transcripts

We have previously shown that tumours bearing proviruses in the *int*-1 region contain polyadenylated transcripts that anneal with probe C, whereas no RNA homologous to probe C is detectable in normal mammary glands[13]. The abundance of the *int*-1 transcripts is not great; less than 10 copies per cell have been estimated by three independent methods (unpublished results).

To judge the mechanism by which the insertion mutations activate expression of *int*-1, it was necessary to determine the direction of transcription of the cellular gene. The *Bam*HI–*Eco*RI fragment that constitutes probe C was recloned in both orientations in the bacteriophage vector M13. Restriction mapping of the replicative forms established the orientation of each insert and hence the polarity of strands present in single-stranded virion DNA (data not shown). Radioactive probes were synthesized by random priming on templates provided by two phages, each bearing one of the two strands. Only one of these probes was found to anneal to RNA from tumour 44, previously shown to contain an *int*-1 transcript 2.6 kb in length (Fig. 4*a*); the composition of the probe established the direction of transcription to be from left to right on the *int*-1 map as presented in Fig. 3.

The *int*-1 transcripts characterized in our earlier report were, like those in tumour 44, approximately 2.6 kb long[13]. In a wider survey of all those tumours from which undegraded polyadenylated RNA could be obtained, we discovered atypical *int*-1 transcripts of 3.2 kb in tumour 11 and of 3.8 kb in tumours 12 and 15 (Fig. 4*b*). In these three tumours, no 2.6-kb *int*-1 RNA was found. The conventional 2.6 kb *int*-1 RNA species was present in all the other tested tumours with *int*-1 insertions (for example, in tumours 24 and 13 in Fig. 4*b*) and in one tumour (number 14) in which an *int*-1 mutation has not been found (unpublished data).

The probable composition of the larger, atypical RNA species was suggested by an intriguing correlation with the site of insertion: in tumours 11, 12 and 15, integration of proviral DNA occurred within or near the right-hand boundary of the region represented by probe C (see Fig. 2). (Suitable RNA samples were not available from the other tumours, 53 and 55, with insertions in this region.) If the proviruses were located within the transcribed domain, upstream from the natural polyadenylation site for *int*-1 RNA, the 5′ LTR would be appropriately positioned to provide a surrogate polyadenylation site. The enlarged size of the *int*-1 transcript could then be ascribed to the length of the U3 region of the MMTV LTR (~1.2 kb)[14–16]. A similar situation has been encountered in an avian leukosis virus (ALV) insertion mutant affecting the chicken c-*myc* locus[10].

It was not possible to test this explanation by attempting to anneal a labelled probe for the MMTV LTR directly to gel fractionated RNA, because virus-specific RNA transcribed in a normal fashion from proviral DNA was vastly more abundant than transcripts from *int*-1. We attempted to circumvent this problem by using the 'sandwich hybridization' procedure[10,16] to test for RNA molecules containing MMTV U3 sequences covalently linked to *int*-1 sequences. Restriction fragments of phage DNA containing a portion of the *int*-1 domain were fractionated in an agarose gel, transferred to nitrocellulose filters, and annealed with unlabelled RNA from tumour 12 (containing a 3.2 kb transcript) or from tumour 13 (with a conventional 2.6 kb transcript). After removal of unannealed RNA, the filter was incubated with a ^{32}P-labelled *Pst*I fragment containing virtually all of the MMTV LTR. One autoradio-

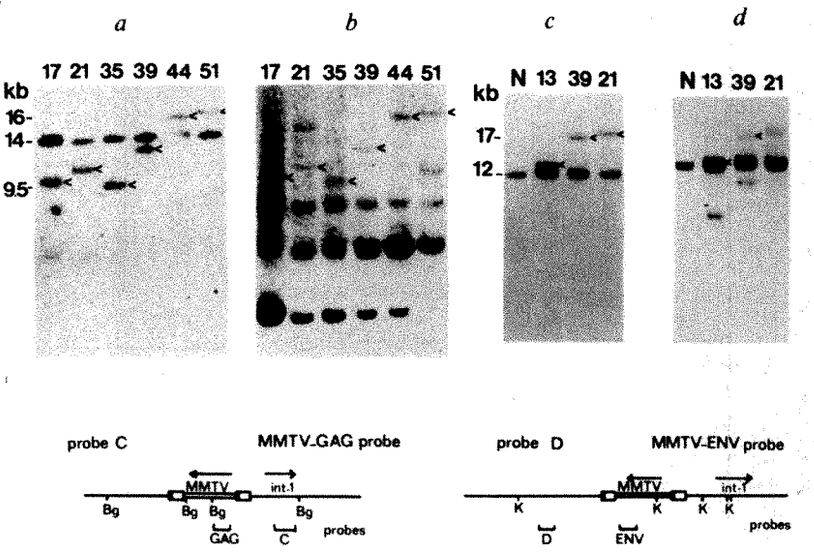

Fig. 1 MMTV proviruses on the 5′ side of the *int*-1 transcriptional unit are in the transcriptional orientation opposite to that of *int*-1. DNA samples (10 μg) from mammary tumours (numbers indicated on top) were digested with *Bgl*II (Bg, panels *a* and *b*) or *Kpn*I (K, panels *c* and *d*), electrophoresed in 0.8% agarose gels, and transferred to nitrocellulose[13]. The filters were first incubated with probe C (*a*) or probe D (*c*), washed and exposed to X-ray film. Subsequently, the probes were removed from the filters and the filters were incubated with MMTV-*gag* probe (*b*) or with MMTV-*env* probe (*d*). The origin of the probes is indicated in the diagrams at the bottom of the figure and in Fig. 3; MMTV-*gag* (3.2 kb) is a *Pvu*II–*Bgl*II fragment obtained from a clone of proviral DNA endogenous to GR mice (ref. 56); MMTV-*env* (1.8 kb) is a *Pst*I fragment derived from MMTV (C3H) DNA and cloned into pBR322 (ref. 57). Arrows indicate tumour-specific bands that show rearrangements of the *int*-1 locus detected with probes C and D and bands in the same position detected with the MMTV probes.

graphic signal, at the position of the *int*-1 fragment homologous to probe C, was observed in the experiment conducted with RNA from tumour 12; no reaction was detected with the sample from tumour 13 (Fig. 4*c*). From this experiment we conclude that *int*-1 and MMTV sequences are covalently joined in transcripts from tumour 12; we presume, but have not proved, that the MMTV sequences are located at the 3′ end of the 3.2-kb transcript in this tumour.

Conservation of the *int*-1 locus

We have proposed that the *int*-1 domain harbours an oncogene that contributes to mammary tumorigenesis following transcriptional activation by proviral integration. However, the locus lacks homology to all tested retroviral oncogenes including *sis*, *ski*, *fos*, *fms* and *yes* (data not shown), as well as the 11 examined previously[13], and it does not anneal with the NIH/3T3 cell transforming gene detected in mammary tumour DNA by Lane *et al.* (ref. 17 and our unpublished results with M. A. Lane and G. M. Cooper). Moreover, we have been unable to measure *int*-1 RNA in a variety of tissues from mature mice (liver, spleen or brain), in cultured mouse cells, or in normal mammary glands from pregnant or lactating females (data not shown). Since no protein product of *int*-1 has been identified, we sought support for the idea that the *int*-1 region contains a coding domain by testing for conserved *int*-1 sequences, homologous to probe C, in the DNA of other vertebrates. As illustrated in Fig. 5, *Bam*HI fragments that anneal effectively with probe C in conditions of only moderately reduced stringency are present in digests of DNA from fish, birds and several mammals, including man. These results are similar to those observed with conserved cellular genes, including the known oncogenes[18]. In addition, as found for the progenitors of some retroviral oncogenes[19], sequences homologous to *int*-1 can be detected in the genome of *Drosophila melanogaster* (lane 1).

Mouse chromosome 15

Specific karyotypic anomalies, some involving putative oncogenes, have recently been found to be associated with a number of different neoplasms[20]. Trisomy of mouse chromosome 13, for example, is frequently observed in MMTV-induced mammary tumours[21]. It was therefore of interest to determine the chromosomal location of *int*-1. To assign *int*-1 to a specific mouse chromosome, we used probe C to detect restriction fragments containing *int*-1 in digests of genomic DNA from 30 Chinese hamster–mouse somatic cell hybrid clones segregating

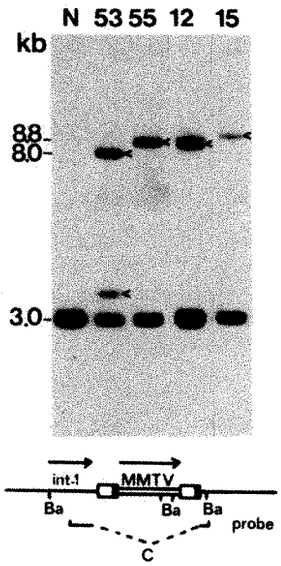

Fig. 2 Proviruses on the 3′ side of *int*-1 are in the same transcriptional orientation as *int*-1. Tumour DNA (number indicated on top, N: normal DNA) was digested with *Bam*HI (Ba), transferred to nitrocellulose filters and annealed with probe C. The sizes of the arrowed, novel restriction fragments and additional mapping data (not shown) show that the proviruses were integrated as drawn at the bottom of the figure. This illustration shows the provirus from tumour 53, providing an explanation for the two novel *int*-1 fragments detected with probe C. Proviruses in the other tumours are located further rightward (see Fig. 3).

mouse chromosomes. These hybrids together contain the full complement of murine chromosomes except for chromosomes 11 and Y (ref. 22). The mouse chromosome complement of each hybrid clone was determined by isozyme and/or karyotype analyses as previously described[22]. The single *int*-1-specific *Eco*RI fragment of 8.6 kb present in digests of genomic mouse DNA could be easily distinguished from the *int*-1-specific *Eco*RI fragment of 2.8 kb derived from Chinese hamster DNA (not shown). An analysis of the segregation of murine *int*-1 and enzyme markers for each of 16 mouse chromosomes (all but 3, 5, 11, 13 and Y) revealed 96% concordant segregation of *int*-1 and arylsulphatase A (AS-1), an enzyme marker for mouse chromosome 15, but discordant segregation of *int*-1 and the

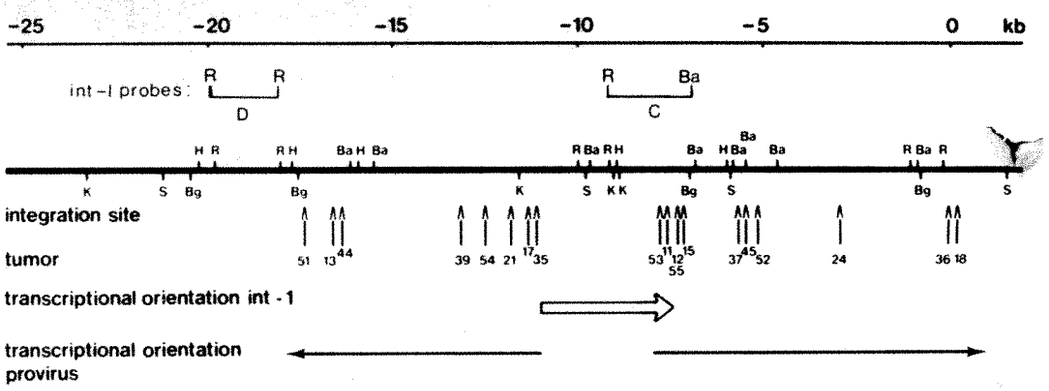

Fig. 3 A map of the proviral integration sites in the *int*-1 locus in C3H mice. Restriction enzyme sites were mapped using C3H and BALB/c chromosomal DNA and DNA from several clones of recombinant bacteriophage containing overlapping inserts from normal BALB/c DNA. Position 0 is defined as the insertion site of the MMTV provirus in tumour 18; this provirus was originally cloned with its flanking DNA to obtain DNA from the *int*-1 locus. Other molecular clones, encompassing positions −22 to +20 on the *int*-1 map, were obtained by sequential screening of a Charon 4A bacteriophage library of normal BALB/c mouse DNA with probes from the *int*-1 region, as described previously[13]. R, *Eco*RI; Ba, *Bam*HI; Bg, *Bgl*II; K, *Kpn*I; S, *Sac*I; H, *Hin*dIII. Probes C and D are fragments of single copy DNA positioned as indicated on the map. Vertical arrows above tumour numbers designate sites of integration. The wide horizontal arrow denotes transcriptional orientation of *int*-1 and the approximate extent of the transcribed domain. The narrow horizontal arrows show the direction of transcription of proviruses integrated in the regions demarcated by the arrows.

other enzyme markers (Table 1). When probe C was removed from the DNA blots and the samples reannealed with a probe for the c-*myc* oncogene (data not shown), we observed perfect concordance between *int*-1 and the mouse *Eco*RI DNA fragment derived from the c-*myc* locus previously assigned to mouse chromosome 15 (refs 23, 24). This finding, consistent with the isoenzyme results, provided further evidence for the assignment of *int*-1 to mouse chromosome 15. Karyotype analyses of 12 selected hybrid clones ruled out an association between *int*-1 and chromosomes 3, 5, 11 13 or Y and were also consistent with the assignment of *int*-1 to chromosome 15 (Table 1). The single discordant clone, which was weakly positive for AS-2 but negative for *int*-1, revealed no evidence of a recognizable mouse chromosome 15. Presumably, this hybrid contains a small, non-recognizable fragment of chromosome 15 which includes AS-2 but not *int*-1. Taken together, these data indicate that *int*-1 is located on mouse chromosome 15.

Implications

The results described here support our previous contention that tumour induction by MMTV involves insertion mutations that activate a previously unknown gene called *int*-1. At the same time they promote confidence in the general proposition that oncogenic viruses lacking viral oncogenes may initiate tumour growth by insertional mechanisms. This hypothesis fosters an experimental strategy for isolation of oncogenes that is formally analogous to what has been termed 'transposon tagging' in other systems[25]: identification of the mutagenic provirus in tumour DNA should lead directly to the isolation of a linked, mutated cellular oncogene. These ideas now receive support from studies of avian B-cell lymphomas induced by at least two different retroviruses[7,11], erythroleukaemia induced by an avian virus that also causes B-cell lymphoma[26], T-cell lymphoma induced by murine leukaemia virus[27] and mammary tumours induced by MMTV[13,28]. At present only circumstantial evidence implicates the affected cellular genes in the oncogenic process: (1) mutation of the same gene in several tumours of the same type; (2) augmented expression and (3) in some cases homology to progenitors of retroviral oncogenes.

Application of the transposon tagging method has led to the discovery of at least two potential mammary oncogenes: the *int*-1 gene commonly implicated in tumours arising in C3H mice and the *int*-2 domain recently found by Peters *et al.*[28] to be interrupted by proviral insertions in about half of the mammary tumours arising in the BR6 mouse strain. These two targets lack evidence of homology with known retroviral oncogenes or with each other, and they are located on different chromosomes (C. Dickson and R. N., unpublished results). In addition, since substantial numbers of tumours lack insertions in either domain, there may be yet other targets for MMTV insertion mutations.

The case for oncogenic roles for *int*-1 and *int*-2 rests primarily on the argument that MMTV proviral DNA appears capable of integration into many different regions in the mouse genome; hence the repeated finding of proviruses at these two loci implies that the tumours are clonal outgrowths of cells[29] with a growth advantage conferred at least in part by the insertion mutations. The case for *int*-1 also rests on the evidence that the locus is transcriptionally active in tumours bearing *int*-1 mutations but not in normal tissues. Although a protein product of *int*-1 has not been identified, a coding function is implied by the conservation of at least part of the transcribed domain during vertebrate evolution (Fig. 5); these findings conform to those obtained with the cellular genes accepted as potential oncogenes by virtue of their homology with retroviral oncogenes.

Our assignment of *int*-1 to mouse chromosome 15 does not offer additional insight into its role as an oncogene: karyotypic abnormalities involving this chromosome have not been reported in mouse mammary tumours, and no endogenous MMTV proviruses have been assigned to chromosome 15 (ref. 30). However, an unrelated oncogene, c-*myc*, also present on mouse chromosome 15, recombines with an immunoglobulin locus on chromosome 12 to produce the translocations found in several plasmacytoma lines[24,31]. Although the distance between *int*-1 and c-*myc* on mouse chromosome 15 is not known, mammary tumours with proviral insertions at *int*-1 do not display abnormal expression of c-*myc* (unpublished data of authors).

The core of the present report concerns the mechanisms by which MMTV proviruses activate expression of *int*-1. In ALV-induced bursal lymphomas, augmented expression of c-*myc* is most commonly achieved by a mechanism referred to as promoter insertion: ALV proviral DNA on the 5′ side of c-*myc* exons in the same transcriptional orientation provides an efficient transcriptional promoter in the form of an LTR[7–10]. However, in the 19 MMTV-induced mammary tumours studied here we have found no instance in which a promoter insertion mechanism activates expression of *int*-1. Instead, MMTV proviruses are positioned either on the 5′ side of the transcriptional template for *int*-1 in the opposite orientation or on the 3′ side in the same orientation. (This rule, however, is not inviolable: in one tumour recently obtained from a BALB/cfC3H mouse, a provirus is present on the 5′ side of the *int*-1 transcriptional domain in the same orientation (R.N., unpublished.)

Previous examples of the two arrangements observed here, in which an LTR cannot serve as promoter for an activated gene, have been described in ALV-induced bursal lymphomas[10]. In these few instances, the effect on expression of c-*myc* was ascribed to a retroviral 'enhancer' element, akin to similar elements first identified in papovavirus genomes[32–38]. Using

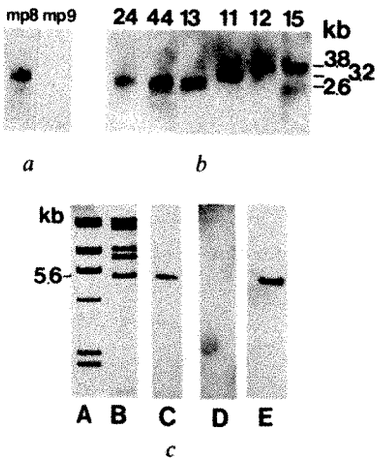

Fig. 4 Analysis of *int*-1 transcription in mammary tumours. *a*, The direction of transcription. 5 μg of polyadenylated RNA from mammary tumour 44 was subjected to electrophoresis in a 1% agarose gel with 2.2 M formaldehyde, transferred to nitrocellulose filters and hybridized with a strand-specific radioactive probe derived by subcloning probe C (a *Bam*HI–*Eco*RI fragment) in the single-stranded bacteriophage derivatives of M13, mp8 and mp9, in both orientations. The autoradiogram shows the hybridization to 2.6-kb RNA with probes made by transcribing the recombinant M13mp8 DNA with reverse transcriptase in the presence of ^{32}P-dCTP with oligomers of calf thymus DNA as random primers. A probe made similarly from the recombinant M13mp9 DNA did not detect a transcript. The direction of transcription of the *Eco*RI–*Bam*HI fragment must proceed from the *Eco*RI site to the *Bam*HI site or from left to right on the *int*-1 map as shown in Fig. 1. *b*, The length of *int*-1 polyadenylated RNA in mammary tumours varies from 2.6 to 3.8 kb. Polyadenylated RNA (5 mg) from mammary tumours with MMTV proviral integrations at the *int*-1 locus was subjected to electrophoresis in 1% agarose gels containing 2.2 M formaldehyde[13] and hybridized with probe C. Tumour numbers are indicated on top (see Fig. 3 for the positions of the proviruses within *int*-1). Tumours 24, 44 and 13 (and also tumours 17, 18, 21, 35, 36, 37, 39, 45) contain a 2.6-kb RNA hybridizing with probe C. Tumour 11 has a 3.2-kb RNA and tumours 12 and 15 have a 3.8-kb RNA species. *c*, Sandwich hybridization demonstrates covalent linkage of *int*-1 sequences to MMTV LTR sequences in tumour 12. DNA from a bacteriophage clone covering the normal *int*-1 region from positions −20 to −3.4 was digested with *Eco*RI and subjected to electrophoresis (lane *B*), next to a marker lane (A) containing wild-type λ DNA digested with *Hin*dIII. DNA was transferred to nitrocellulose filters (several identical filters were prepared from one gel). Direct annealing to radioactive probe C identified a 5.6-kb *Eco*RI fragment (arrow) that contained the *int*-1 transcriptional domain (lane *C*). (This fragment maps from the *Eco*RI site at position −9 in *int*-1 to an *Eco*RI linker at position −3.4.) Other filters were first incubated with unlabelled RNA from tumour 13 (lane *D*) or tumour 12 (lane *E*). These filters were washed and then hybridized to a radioactive probe from the MMTV LTR (a 1.4-kb *Pst*I fragment containing all but 10 bp of the LTR). Only the filter that was annealed first with the RNA from tumour 12 shows hybridization with the *Eco*RI fragment that also hybridized with probe C. Lanes *A* and *B* are photographs of the ethidium-bromide stained gel, the other lanes are autoradiograms.

Methods: 20 μg of poly(A)$^+$ RNA was resuspended in 2 ml of an annealing mix consisting of 50% formamide, 0.5 M NaCl, 20 mM PIPES *p*H 6.8, 5 mM Na_2EDTA, 0.4% SDS, 250 μg ml^{-1} poly(A), 2×Denhardt's solution, and 200 μg ml^{-1} carrier yeast RNA. This solution was applied to the filter-bound DNA and incubated for 24 h at 41 °C. The filter was washed twice at 53 °C for 15 min with 0.1×SSC, 0.1% SDS. The filter was blotted dry, annealed to MMTV–LTR probe (2×10^6 c.p.m.), washed twice for 1 h at 37 °C with 0.1×SSC, 0.1% SDS, dried and autoradiographed.

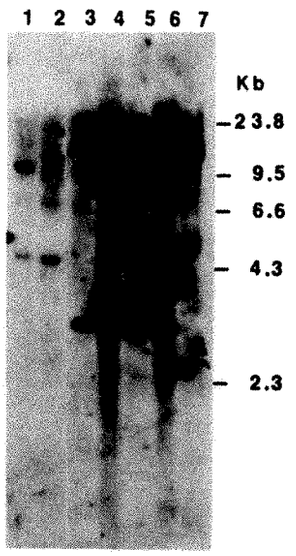

Fig. 5 Sequences homologous to *int*-1 are present in all vertebrates and *Drosophila*. Cellular DNA (10–15 μg) from the indicated sources was digested with *Bam*HI, subjected to electrophoresis in an 0.8% agarose gel, transferred to nitrocellulose filters, and annealed with probe C in 37.5% formamide, 3×SSC, at 42 °C. After washing in 2×SSC at 50 °C, the filter was exposed to X-ray film for 6 days. Lane 1, adult *Drosophila melanogaster* (Oregon-S strain); lane 2, fish (*X. helleri*); lane 3, chicken erythrocytes (strain 15×7); lane 4, mouse liver (BALB/c strain); lane 5, rat hepatoma cells (H4IIE line, ATCC); lane 6, domestic cat liver; lane 7, human mammary epithelial cells (HBL100 line; ATCC). Numbers at the right (in kb) refer to the positions of *Hin*dIII fragments of λ phage DNA present in the same gel.

DNA transformation techniques, retroviral[39–42] and cellular[43] sequences with enhancer activity have been shown to act in *cis*, over variable distances and independent of polarity, to improve the efficiency of heterologous promoters.

Our evidence that MMTV DNA can activate the expression of a previously silent gene in tumours has several of the characteristics of enhancement: the mechanism of activation operates in a manner independent of orientation, over distances of at least 10 kb, and in *cis* rather than *trans*. The basis for claiming *cis* activation is our observation that insertions between positions −8 and −6 on the *int*-1 map are associated only with transcripts of atypically large size (Fig. 4*b*), despite the persistence of the chromosome bearing a normal *int*-1 allele; we conclude that only the physically rearranged locus has been activated. Other aspects of the situation may also be germane to a consideration of mechanism. (1) The observed effect is conversion of an ostensibly silent gene to one expressed at low levels (less than 10 RNA molecules per cell), rather than to amplify expression of a gene normally transcribed. (2) Enhancer functions are likely to be cell specific[44–49] and perhaps target gene specific, so it is plausible that the MMTV enhancer works preferentially in mammary cells and upon *int*-1. (3) Initiation of MMTV transcription is greatly stimulated by glucocorticoid hormones[50], and the hormonal response displays some of the properties of enhancement[51–53]; hence it is possible that activation of *int*-1 is also affected by physiological doses of hormone. This final point should be amenable to direct test by growing mouse mammary tumour cells with *int*-1 insertions in controlled conditions in culture.

The use of an MMTV enhancer function to activate expression of *int*-1 could explain the uniform orientations of proviruses on each side of the proposed transcriptional unit (see Fig. 3). Enhancers are thought to act only or preferentially upon proximal promoters[54,55]; if the MMTV enhancer is located on the 5′ side of the initiation site for viral RNA, within the 1.2-kb U3 sequence of the LTR, then proviruses would require the orientations observed to avoid interposing an MMTV promoter between the enhancer and its *int*-1 target.

We thank P. Borst, C. Dickson, J. Majors and W. Hayward for discussions and comments on the manuscript, M. Simon, M. Schwab and C. Hammond for materials, M. Paape for technical assistance, N. van Nuland and J. Marinos for preparing the manuscript, and E. Stavnezer, C. Sherr, I. Verma, R. Gallo and M. Yoshida for provision of cloned viral oncogenes. Correlation between segmental flexibility and effector function of antibodies

V. T. Oi, T. M. Vuong, R. Hardy, J. Reidler, J. Dangl, L. A. Herzenberg & L. Stryer

Department of Structural Biology, Sherman Fairchild Center and the Department of Genetics, Stanford University School of Medicine, Stanford California 94305, USA

Mouse monoclonal anti-dansyl antibodies with the same antigen-binding sites but different heavy chain constant region were generated. The extent of segmental flexibility in times of nanoseconds and the capacity to fix complement wer greatest for IgG2b, intermediate for IgG2a, and least for IgG1 and IgE. Hence, the effector functions of immunoglobuli isotypes may be controlled in part by the freedom of movement of their Fab arms.

IMMUNOGLOBULIN G is a flexible Y-shaped molecule. The two antigen-binding Fab units of IgG are joined to an Fc unit at a hinge that allows the angle between the Fab parts to vary over a broad angular range, as shown by hydrodynamic[1], electron microscopic[2,3], and X-ray crystallographic studies[4–6]. Nanosecond fluorescence polarization measurements have demonstrated that immunoglobulin molecules exhibit segmental flexibility in the nanosecond time range[7–9]. Segmental flexibility is likely to be important in enabling immunoglobulins to bind optimally to multivalent antigens and to carry out certain effector functions. Studies of polyclonal antibody populations have suggested that immunoglobulin classes differ in their degree of segmental flexibility[10–11]. We have explored the relationship between hinge motion and effector function in specially constructed families of homogeneous immunoglobulins. Mouse monoclonal anti-dansyl antibodies with the same antigen-combining sites but different heavy chain constant regions (Fig. 1) were generated by selecting somatic variants in hybridoma cell lines. The extent of segmental flexibility in times of nanoseconds (measured by fluorescence spectroscopy) and the capacity to fix complement were greatest for IgG2b, intermediate for IgG2a, and least for IgG1 and IgE. Hence, the effector functions of immunoglobulin isotypes may be controlled in part by the freedom of movement of their Fab arms.

In most antibody-producing hybridoma cell lines, variant cell arise which produce antibody containing a different heav chain[12]. For example, cells producing IgG2b sometimes aris from a cell line producing IgG1. The frequency of these heavy chain switch variants is ordinarily low (10^{-5}–10^{-6} per gener ation). These rare cells can be separated by fluorescence-acti vated cell sorting on the basis of the appearance of a differen heavy chain on their cell surface[13,14]. In these switch variants the light chain remains the same, whereas V_H becomes joine to a different C_H. Consequently, the antigen-combining site i the same as in the parent, despite the change in the heavy-chai constant region. Many of these switch variants are stable an can be cloned.

We chose to generate a family of homogeneous mouse anti dansyl (DNS) antibodies for two reasons. First, the fluorescenc emission spectrum of the bound dansyl chromophore is ver responsive to the polarity of its environment[15], making it convenient and sensitive indicator of whether the antigen combining site of the switch variant antibody is in fact the sam as that of the parent line. Second, the bound dansyl chromophor has an excited state lifetime suitable for determining the seg mental flexibility of immunoglobulin isotypes by nanosecon fluorescence polarization spectroscopy[16]. Variant hybridom cell lines producing different immunoglobulin isotypes wer

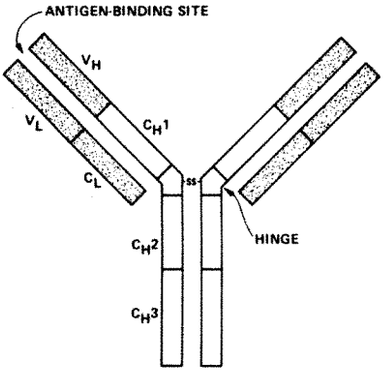

Fig. 1 Schematic diagram of immunoglobulin G. In each family of isotypes, the V_L, C_L and V_H regions are the same. The hinge is located between the C_H1 and C_H2 domains.

Table 1 Mean rotational correlation times of immunoglobulin isotypes and their Fab fragments

	$\langle\phi\rangle$ (ns)	
	No DTT	With DTT
DNS1 family		
Intact immunoglobulin		
IgE	124	88
IgG1	81	58
IgG2a	60	51
IgG2b	47	42
Fab fragment		
IgG1	28	28
IgG2a	28	28
IgG2b	29	29
DNS3 family		
Intact immunoglobulin		
IgG1	93	55
IgG2b	46	45

selected by using affinity-purified goat and rabbit anti-mouse heavy-chain sera and a panel of hybridoma anti-mouse immunoglobulin allotype antibodies[14]. IgG2b, IgG2a and IgE anti-DNS antibody-producing cell lines were isolated starting with the mouse IgG1 anti-DNS hybridoma cell line DNS1 (Igh^a allotype, also designated as 27-44). Our previous nanosecond fluorescence study[16] showed that IgG1 from this mouse cell line is more rigid than is polyclonal rabbit anti-dansyl antibody. The cell lineage of the DNS1 family is: IgG1 (27-44) → IgG2b (27-35) → IgGa (27-13) → IgE (27-74). A cell line containing a different IgG1 anti-dansyl combining site, DNS3 (Igh^b allotype, also designated as 44-10), served as the source of another anti-dansyl IgG2b (44-32).

Two-dimensional gel electrophoresis of antibodies[17,18] produced by the DNS1 family shows that the heavy chain synthesized by each member has the electrophoretic mobility expected for γ1, γ2b, γ2a and ε chains (Fig. 2). Also, these gels show that the light chains produced by this family are identical. Corresponding results were obtained for the DNS3 family. Heavy chains synthesized by these variant cells in the presence of tunicamycin, a known inhibitor of asparagine-linked glycosylation[19-21], have a greater electrophoretic mobility than do those synthesized in its absence. This finding suggests that each variant isotype is normally glycosylated in the absence of tunicamycin. The fluorescence emission spectra of ε-dansyl-L-lysine bound to switch variants of the DNS1 cell line are identical to that of the parent cell antibody (Fig. 3), strongly suggesting that the DNS1 family has the same antigen-combining site. Likewise, both DNS3 isotypes have identical dansyl fluorescence emission spectra. Also, the dissociation constant of the antibody-hapten complex is the same within the DNS family ($K_d = 17 \pm 1$ nM) and the DNS3 family ($K_d = 3 \pm 1$ nM).

Segmental flexibility

The segmental flexibility of these anti-dansyl immunoglobulins was determined by measuring their fluorescence polarization kinetics in the nanosecond time range[7,16,22]. A solution of immunoglobulin containing bound ε-dansyl-L-lysine is excited by a picosecond pulse of vertically-polarized light. Photoselection produces an ensemble of excited choromophores preferentially aligned in the vertical direction. The orientations of these excited molecules then become randomized by rotational brownian motion. The rate of randomization depends on the size and shape of the immunoglobulin, and also on its modes of flexibility. These motions can be monitored by measuring the intensities of the vertically-polarized [$y(t)$] and horizontally-polarized [$x(t)$] components of the fluorescence emission as a function of time following the excitation pulse. The most informative parameter is the emission anisotropy $A(t)$, which is defined as

$$A(t) = \frac{y(t) - x(t)}{y(t) + 2x(t)}$$

The emission anisotropy kinetics of a chromophore rotating in common with a rigid sphere is given by $A(t) = A_0 \exp(-t/\phi)$, where A_0 is the initial value of the emission anisotropy and ϕ is the rotational correlation time. For a nonspherical particle, $A(t)$ is more complex, consisting of up to five exponential terms. For a rigid ellipsoid, $A(t)$ is a sum of three exponential decays that depend on the volume and axial ratio of the ellipsoid and on the directions of the transition moment of the emitting chromophore. A rigorous theory for the emission anisotropy kinetics of rigid and segmentally flexible Y-shaped molecules has not yet been developed. Emission anisotropy data for immunoglobulins have instead been interpreted phenomenologically by comparing observed $A(t)$ curves with those

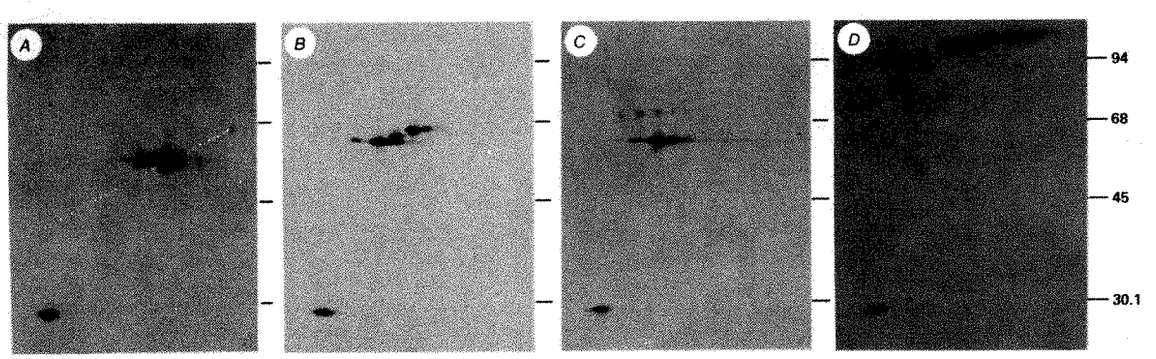

Fig. 2 Two-dimensional gel electrophoresis autoradiogram patterns of antibodies produced by the DNS1 family. *A*, IgG1; *B*, IgG2b; *C*, IgG2a; and *D*, IgE. The horizontal direction corresponds to a non-equilibrium *p*H gradient (low *p*I at the left) and the vertical direction corresponds to sodium dodecyl sulphate polyacrylamide gel electrophoresis[17,18]. Antibodies were labelled biosynthetically with ^{35}S-methionine. Secreted anti-dansyl antibodies in the culture supernatants were precipitated with monoclonal antibodies specific for γ1 (*A*), γ2b (*B*), γ2a (*C*) and a rabbit anti-mouse IgE (*D*). The spot in the lower left-hand corner appears in the same position in each autoradiogram, providing strong confirmation that the κ light chain is the same in each. The multiple spots in the upper half of each gel are typical for myeloma and hybridoma heavy chains. The heterogeneity probably arises from differences in deamidation and glycosylation.

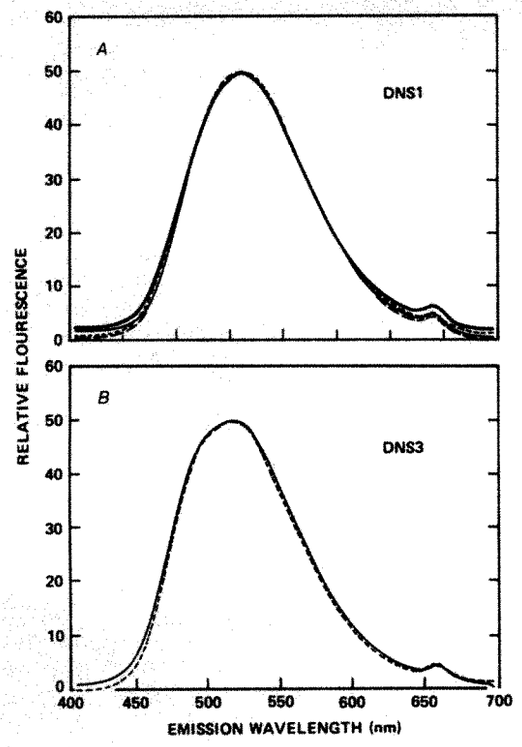

Fig. 3 Fluorescence emission spectra of ε-dansyl-L-lysine bound to isotypes of the DNS1 (*A*) and DNS3 (*B*) families. The spectra of isotypes within a family are virtually superposable. The excitation wavelength was 340 nm.

calculated for rigid spheres and ellipsoids. In this regard, the mean rotational correlation time $\langle\phi\rangle$ can be informative. $A(t$ is fitted to a sum of two exponential decays, $a_1 \exp(-t/\phi_1) + a_2 \exp(-t/\phi_2)$, to give $\langle\phi\rangle$, which is equal to $(a_1\phi_1 + a_2\phi_2)/(a_1 + a_2)$. Rigid nonspherical particles have a $\langle\phi\rangle$ greater than ϕ for a rigid sphere of the same volume. Consequently, a particle irrespective of shape, must be flexible if its $\langle\phi\rangle$ is less than ϕ_{sphere}

Emission anisotropy kinetics were measured using a mode locked argon-ion laser and synchronously pumped rhodamin 6G dye laser as the excitation source and a single-photon counting detection system, as described previously[16]. Picosecond pulses at 325 nm were produced by doubling the frequency of the 650 nm output of the dye laser. All fluorescence studies were carried out at 20 °C. $A(t)$ curves for the DNS1 family are shown in Fig. 4*A*. The striking finding is that the IgG1, IgG2a and IgG2b isotypes of this family display markedly different $A(t$ curves. Their $\langle\phi\rangle$ values are 81, 60 and 47 ns, respectively. These immunoglobulins have virtually identical molecular weights and sedimentation coefficients (6.8, 6.67, and 6.70, respectively; V Schumaker and M. Phillips, personal communication), which means that their molecular volumes and time-averaged shapes are nearly the same. Furthermore, the Fab fragments obtained from these isotypes have nearly the same $\langle\phi\rangle$ values (Table 1) The orientation of the bound dansyl chromophore with respect to the long axis of the Fab unit is identical or nearly so in these isotypes because they possess identical antigen-combining sites Thus, the large difference in the $A(t)$ curves (Fig. 4*A*) are almost certainly due to different extents of segmental flexibility in the intact immunoglobulins. IgG1 is the most rigid, IgG2a is intermediate, and IgG2b is the most flexible of the three isotypes

IgE is like IgG1 in being more rigid than IgG2a and IgG2b (Fig. 4*A*). The $\langle\phi\rangle$ value for IgE can be compared with those of the three IgG isotypes by scaling its $\langle\phi\rangle$ to take into account its 190,000 molecular weight[23] compared with 150,000 for IgG

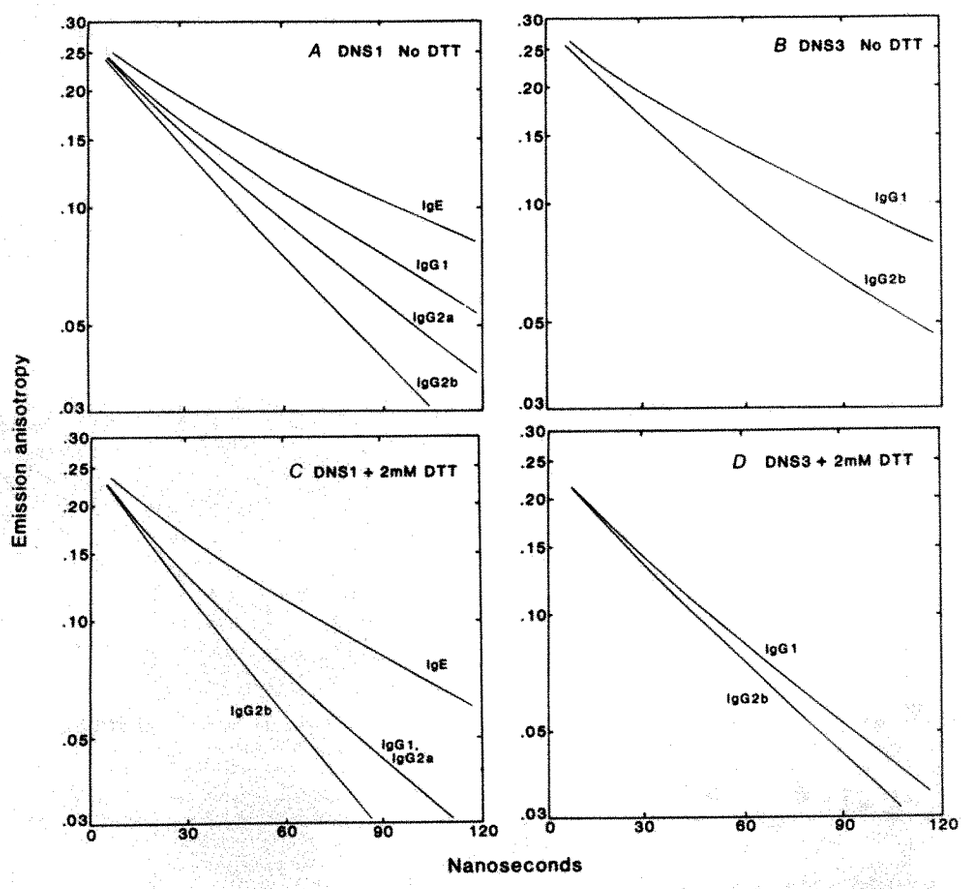

Fig. 4 Nanosecond emission anisotropy kinetics of ε-dansyl-L-lysine bound to immunoglobulins of the DNS1 family in the absence (*A*) and presence (*B*) of 2 mM DTT; and the DNS3 family in the absence (*C*) and presence (*D*) of 2 mM DTT. The temperature was 20 °C.

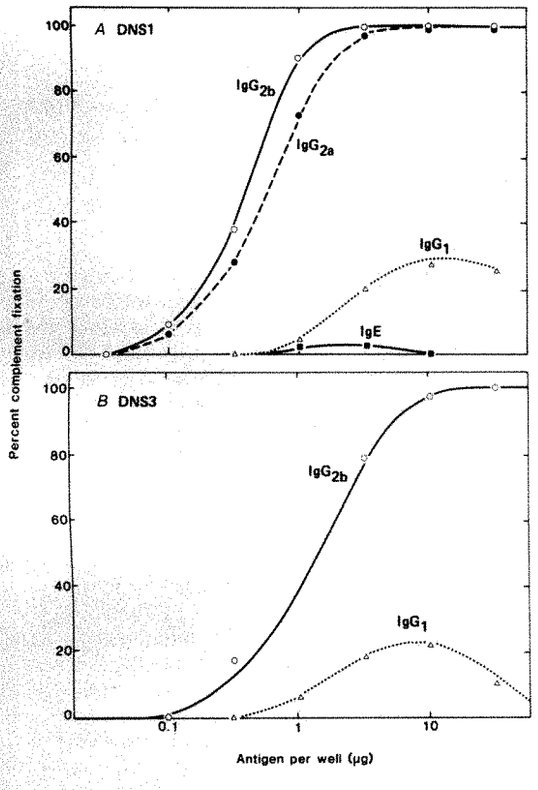

Fig. 5 Complement-fixation by the DNS1 (*A*) and DNS3 (*B*) family. A microcomplement consumption assay using ^{51}Cr release from haemolysin-treated sheep erythrocytes similar to that described previously[25] was used to measure complement fixation by the DNS1 and DNS3 family. Immunoglobulin (10 μg per 25 μl), DNS-bovine serum albumin dilutions (in 25 μl) and complement (2 CH-50 units in 25 μl) were combined in wells of a 96 well microtitre plate and incubated for 45 min at 37 °C. Next, 50 μl of a 2% solution of activated, ^{51}Cr-loaded erythrocytes was added to each well and after a further 45 min incubation at 37 °C the non-lysed cells were pelleted by centrifugation of the plates. 50-μl aliquots of supernatant were collected from each well and counted on a gamma counter set for ^{51}Cr.

The scaled $\langle\phi\rangle$ value for IgE is $124\times(150/190)=98$ ns, which is even larger than the 81 ns value for IgGl. The sedimentation coefficient of 8.35 S for this IgE (V. Schumaker and M. Phillips, personal communication) corresponds to 6.59 S when scaled for the molecular weight difference between IgE and IgG. This is consistent with the time-averaged shape (as expressed by the translational diffusion coefficient) of IgE being very similar to that of the three IgG isotypes.

Reduction of the disulphide bonds between the heavy chains in the vicinity of the hinge between the Fab and Fc units[16,24] provided additional information concerning the degree of segmental flexibility of the isotypes. The addition of 2 mM dithiothreitol (DTT) leads to a large decrease in $\langle\phi\rangle$ for IgE and IgG1 (Fig. 4*B*, Table 1). Reduction of the interchain disulphides lowers $\langle\phi\rangle$ of IgE from 124 to 88 ns, and that of IgG1 from 81 to 58 ns. DTT has no effect on $\langle\phi\rangle$ for the Fab fragment of IgG1. Thus, DTT lowers $\langle\phi\rangle$ of intact IgG1 by opening up a restricted hinge region. In contrast, DTT has almost no effect on $\langle\phi\rangle$ of IgG2a and IgG2b because the Fab units of these antibody molecules have a high degree of rotational freedom even before reduction of the interchain disulphides.

A large difference in segmental flexibility was also observed within the DNS3 family (Fig. 4*C* and Table 1). IgG2b is again much more flexible than IgG1, as evidenced by their $A(t)$ curves and $\langle\phi\rangle$ values. Also, DTT markedly decreases $\langle\phi\rangle$ of IgG1 and has little effect on $\langle\phi\rangle$ of the more flexible IgG2b (Fig. 4*D* and Table 1).

Complement-fixation effectiveness

The ability of these antibody molecules to fix complement was measured using a micro-complement consumption assay[25]. Dansylated bovine serum albumin served as the antigen. In the DNS1 family, IgG2b is most effective in fixing complement, and IgG2a is also highly effective (Fig. 5*A*). In constrast, IgG1 fixes less complement and required ten-fold more antigen to trigger complement fixation. IgE exhibits negligible complement-fixation activity. Likewise, in the DNS3 family, IgG2b fixes more complement than does IgG1 and does so at a lower concentration of antigen (Fig. 5*B*). The isotypes that fix complement most effectively, IgG2a and IgG2b, also exhibit the highest degree of segmental flexibility.

Two families of immunoglobulin isotypes with identical antigen-binding sites were constructed using somatic cell genetics techniques. Nanosecond fluorescence polarization studies of these monoclonal anti-dansyl isotypes have revealed striking differences in their extents of segmental flexibility. IgG2b is the most flexible, IgG2a is less flexible, and IgG1 and IgE are relatively rigid. The degree of molecular motion at the hinge in times of nanoseconds is correlated with the ability of these molecules to fix complement. This correlation may be more than fortuitous. Segmental flexibility may promote complement fixation by enhancing multivalent binding, facilitating the transmission of conformational changes from the Fab units to the effector domain on the Fc unit, or enabling the Fc unit to assume a conformation favourable for complement fixation. It will be very interesting to further explore the relationship between flexibility and effector function by engineering a series of immunoglobulins in which the hinge is deleted, elongated, or modified to alter the rotational mobility of the Fab arms. For example, it would be instructive to study a chimaeric immunoglobulin containing an IgG1 hinge and IgG2b C_H2 and C_H3 domains. We predict that such an immunoglobulin would fix complement less effectively than a normal IgG2b molecule. Segmental flexibility is likely to be one factor correlated with complement fixation. The construction of immunoglobulin genes with novel combinations of domains or with site-specific mutations and their subsequent insertion into lymphoid cell lines should lead to deeper insights into how immunoglobulins mediate their distinctive functions. Methods for expressing designed immunoglobulins have recently been developed[26,27].

Monoclonal antibodies directed against tumour-specific antigens are now being used to treat certain malignancies[28]. It will be important to learn whether the therapeutic effectiveness of a tumour-specific antibody depends on its isotype as well as on its antigen-binding properties. The capacity of such antibodies to interact optimally with tumour-specific antigens on cell surfaces may be influenced by their segmental flexibility.

Large anisotropy in the Universe does not prevent inflation

Marek Demianski*

Center for Relativity, Department of Physics,
The University of Texas at Austin, Austin, Texas 78712, USA

The inflationary model in which the Universe passes through an exponentially expanding phase can explain a few cosmological conundrums of the standard big-bang model. It is therefore interesting to study the stability of this model. It has been demonstrated that the inflationary scenario is stable with respect to density, velocity and gravitational wave perturbations[1–3]. Here I show that the new inflationary model is compatible with large initial anisotropy. The initial anisotropic energy density could be many orders of magnitude larger than the initial radiation energy density.

The standard hot big-bang model of the Universe is remarkably simple and provides an amazingly accurate description of its evolution. There are, however, several observational facts which remain unexplained in this model, for example, the present high degree of isotropy of the microwave background radiation, the large scale homogeneity, and near critical energy density of the Universe.

The inflationary model of the early evolution of the Universe[4–6] explains these facts without altering the basic predictions of the big bang model. Guth[4] noticed that the first-order phase transition predicted by grand unified theories (GUTs), which occurs when temperature T is of the order of 10^{14} GeV, could have profound cosmological consequences. The inflationary scenario requires Higgs field effective potential $V(\phi)$ to have a global minimum at zero temperature. This global minimum is called the true vacuum. The zero temperature effective potential should also have a second metastable extremum at $\phi=0$ (the false vacuum). Furthermore, one assumes that there is a critical temperature $T_c \approx 10^{14}$ GeV above which the finite temperature effective potential has a lower value near the false vacuum than it has near the true vacuum. For any small temperature $T>0$ the false vacuum is stabilized by a barrier in the finite temperature effective potential. The height of this barrier is of the order of T^4 and its width is of the order of T.

If at the very early stages of evolution the Universe contained a hot region ($T>10^{14}$ GeV), which was isotropically expanding fast enough to cool to T_c before gravitational effects could cause it to collapse, then this region will cool to T_c and supercool. The constant false vacuum energy density determines then the rate of expansion and this region expands exponentially. This expansion can be described by the de Sitter metric with the false vacuum energy density having the role of a cosmological constant.

The Higgs field fluctuates around the false vacuum. Some fluctuations begin to grow and at some point become large enough to be described by a classical evolution equation. At the moment when evolution of fluctuations could be described by the classical equation the fluctuations should be small. If the fluctuations grow very slowly, allowing many e folding times to pass, this single fluctuation region could grow to become larger than the present Universe. Finally, having reached the steep part of the potential, the field rapidly rolls down and oscillates about the true vacuum position. These oscillations are quickly damped out through coupling to other fields and the released energy is thermalized. The Universe reheats to temperature $T \approx T_c \approx 10^{14}$ GeV. The subsequent evolution follows the standard model.

The inflationary scenario can explain several cosmological conundrums, namely the isotropy of the microwave background radiation (the horizon problem), the observed large-scale homogeneity, the near critical energy density, and small number density of magnetic monopoles[7].

It has been demonstrated that the inflationary scenario is stable with respect to inhomogeneous density, velocity, and gravitational wave perturbations[1–3]. Hawking and Moss[8] suggested that there is a cosmological 'no hair' theorem and the de Sitter space is dynamically stable. Barrow and Turner[9] pointed out that in the inflationary model proposed by Guth[4] large anisotropy prevents the de Sitter phase from occurring. I now show that the new inflationary scenario can tolerate very large homogeneous initial anisotropy.

Let us consider an anisotropic homogeneous Bianchi type 1 universe filled with radiation and constant false vacuum energy density ρ_v. The evolution of this model is described by

$$\dot{R}^2 = \frac{8\pi G}{3}(\rho_r+\rho_v)R^2 + \frac{8\pi G}{3}\frac{a^2}{R^4} \tag{1}$$

and

$$\rho_r R^4 = \text{constant} \tag{2}$$

where R is related to the volume expansion parameter by $\dot{V}/V = 3\dot{R}/R$, ρ_r is the radiation energy density, and a is a constant related to the initial anisotropy. Equation (1) can be rewritten in the form

$$\frac{dz}{d\tau} = 2\left(z^2+1+\frac{\beta}{z}\right)^{1/2} \tag{3}$$

where

$$\tau = \chi t = \left(\frac{8\pi G}{3}\rho_v\right)^{1/2} t$$

$$z = \left(\frac{R}{R_0}\right)^2 \left(\frac{\rho_v}{\rho_r(0)}\right)^{1/2}$$

and

$$\beta = \frac{a^2}{R_0{}^6\rho_r(0)}\left(\frac{\rho_v}{\rho_r(0)}\right)^{1/2} = \frac{\rho_{an}(0)}{\rho_r(0)}\left(\frac{\rho_v}{\rho_r(0)}\right)^{1/2}$$

where R_0 is a constant, and $\rho_r(0)$ and $\rho_{an}(0)$ are the initial energy densities of radiation and anisotropy. In this equation z^2 is related to the false vacuum energy density, 1 to the radiation energy density, and β/z to the anisotropic energy density.

At the very early stage of expansion, when z is very small, the anisotropic energy density determines the expansion rate of the Universe, so that $z=\beta^{1/3}(3\tau)^{2/3}$. We are interested in a situation when the anisotropic energy density determines the expansion rate of the Universe at an epoch when the Universe

0028–0836/84/020140—02$01.00

cools below T_c. When $T \approx T_c$ the radiation energy density and the vacuum energy density are equal, and $z = 1$. The anisotropic energy density will dominate the dynamics of expansion at that epoch if $\beta \gg 1$. Let us assume that the temperature of radiation at the Planck time $t_p = (G\hbar/c^5)^{1/2} = 0.5 \times 10^{-43}$ s is equal to Planck temperature $T_p = 1.2 \times 10^{19}$ GeV, then $\beta \gg 1$ if the initial anisotropic energy density $\rho_{an}(0) \gg 10^{10}\ \rho_r(0)$. The vacuum energy density starts to have a dynamically dominant role when $z = \beta^{1/3}$, $(\tau = \frac{1}{3})$. The de Sitter phase prevails if the small fluctuations of the Higgs field generated at the moment when or after the Universe cools to T_c ($\rho_v = \rho_r$, $z = 1$, $\tau = \frac{1}{3}(\beta)^{1/2}$) do not have enough time to grow significantly by the time when the vacuum energy density starts to determine the expansion rate of the Universe.

Let us assume that the initial fluctuations of the Higgs field are large enough to be described by the classical evolution equation

$$\ddot{\phi} + 3H\dot{\phi} = \lambda\phi^3 \tag{4}$$

where $\lambda \approx \frac{1}{2}$, and H is the Hubble constant, in our case $H = \frac{1}{3}t$. Assuming that initially, when $T = T_c$, $\phi(\tau = \frac{1}{3}(\beta)^{1/2}) = \phi_i$ we obtain an approximate solution of equation (4)

$$\phi = \frac{\phi_i}{\left(1 - \frac{\lambda}{2}\left(\frac{\phi_i}{\chi}\right)^2\left(\tau^2 - \frac{1}{9\beta}\right)\right)^{1/2}} \tag{5}$$

Following Guth[7] we assume that the initial fluctuations are of the order of thermal fluctuations and $\phi_i \approx 0.23\chi$. By the time that the vacuum energy density starts to determine the expansion rate of the Universe the fluctuations grow only insignificantly, $\phi(\tau = \frac{1}{3})/\phi_i - 1 \approx 7 \times 10^{-4}$. Therefore, the vacuum energy survives up to the moment when it starts to have a dominant dynamical role. The Universe enters the de Sitter phase and expands exponentially. The evolution of small fluctuations of the Higgs field in the de Sitter universe has been studied by Guth[7]. He showed that the fluctuations grow slowly and the Universe stays in the false vacuum state for many e folding times. The new inflationary model is, therefore, compatible with very large initial anisotropy. The initial anisotropic energy density can be many orders of magnitude larger than the intial radiation energy density.

One might ask what happens when due to coupling to other fields the anisotropic energy density is dissipated and released in the form of heat. This will only delay the moment of the phase transition but it does not change our main conclusion.

Recently, Futamase[10] noticed that anisotropy will change the form of the effective potential $V(\phi)$. The additional terms are proportional to the anisotropic energy density and they distort the potential in a similar way as the high temperature corrections. Due to this additional bump in the potential the transition from the false to the true vacuum state would be slower, making the inflationary scenario even more plausible.

I thank the members of the Department of Physics of the University of Texas at Austin, Center for Relativity, and Center for Theoretical Physics for hospitality and support.

Correlation of bristlecone pine ring widths with atmospheric ^{14}C variations: a climate–Sun relation

C. P. Sonett

Department of Planetary Sciences and Lunar and Planetary Laboratory, University of Arizona Tucson, Arizona 85721, USA

H. E. Suess

Department of Chemistry, University of California at San Diego, La Jolla, California 93093, USA

Recent measurements by Stuiver and Quay[1] on wood growth during the past millennium confirm in an impressive way the contention that, in addition to being affected by the geomagnetic dipole moment, the production rate of ^{14}C is mediated by interplanetary modulation arising from solar activity, of which the sunspot index is a measure. But Stuiver[2], like others before him, finds no statistically significant correlation with climate indicators, including ring-width data and $\Delta^{14}C$. However, the data presented here show a case of an unusually convincing correlation between variations of cosmic ray-produced ^{14}C activity of the CO_2 in the terrestrial atmosphere during the past five millennia[3,4] and annual growth ring widths for bristlecone pine wood from one particular area, that of Campito Mountain in eastern California.

The annual values of the Campito Mountain series were supplied by V. C. LaMarche of the University of Arizona Laboratory of Tree Ring Research. Twenty-year averages have been published by Lamb[5]. The bristlecone pine growth ring sequence was determined specifically to investigate the influence of climatic conditions on the growth rates of bristlecone pine trees. This growth ring sequence extends from 3405 BC to AD 1979. The sample trees are from the upper limit of the altitude band in which the bristlecone pine is found on Campito Mountain. For the high altitude (3,384 m) bristlecone pine at the upper growth region limit (from which the bristlecone data discussed here are drawn) the primary stress-induced growth effect is thought to be temperature[6,7].

The correlation of $\Delta^{14}C$ and tree-ring sequences is based on power spectral densities (PSDs) and cross-covariance; the PSDs are discussed first. The power spectrum of $\Delta^{14}C$ deduced from the La Jolla measurements of $\Delta^{14}C$ in samples of bristlecone pine wood from the White Mountains of California, has been published previously[8]. Essentially the same data are used here for a more detailed calculation of the $\Delta^{14}C$ spectrum. Additional comparisons (not shown here) have been made using the $\Delta^{14}C$ series reported by a workshop held at the University of Arizona[9]. A lesser correlation with a limber pine sequence from Mount San Gorgonio in Southern California has also been observed. Wood used for the ^{14}C determinations was preferentially selected from trees with abnormally wide rings.

The $\Delta^{14}C$ La Jolla measurements of bristlecone pine samples, dated dendrochronologically by Ferguson[4], were used. They are unequally spaced in time, and therefore must be detrended and interpolated prior to computation. We first remove the quasi-sinusoid[3] (thought to arise from secular drift in the intensity of the geomagnetic field), followed by application of a cubic spline[10], quadratic detrending and finally interpolation at 10-yr intervals. To avoid extreme tensioning of the spline used for interpolation and yet cover all data points the highest frequency contributions are removed by a ±20 yr moving linear least-squares estimator which replaces each interpolated point by a value which dampens the highest frequency components. The LaMarche bristlecone pine ring-width sequence, consisting of yearly data points, is filtered and decimated by 10; the initial computations were made using the sequences truncated to the

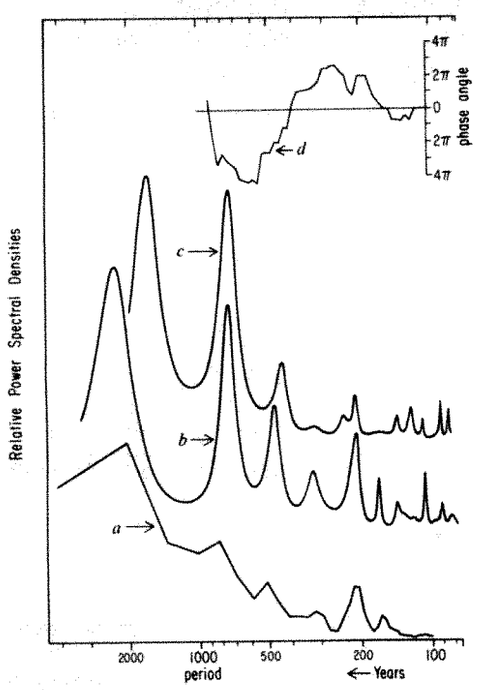

Fig. 1 Power spectral densities of the La Jolla $\Delta^{14}C$ and bristlecone pine tree-ring growth record: *a*, the Neftel *et al.*[8] FFT of the full 8,400-yr record; *b*, the maximum entropy (MEM) spectrum at autoregressive (AR) order 120 of the truncated 5,290-yr (3405 BC–AD 1885) La Jolla record; *c*, the Campito Mountain bristlecone pine (3405 BC–AD 1885) growth ring spectrum at AR order 120; *d*, variation in relative phase between $\Delta^{14}C$ and Campito Mountain bristlecone pine ring growth with frequency and period. The phase is that corresponding to the peak coherence between narrow-banded versions of the original sequences obtained from Fourier spectra filtered to isolate narrow spectral intervals which provide the basis for narrow band $\Delta^{14}C$ and bristlecone pine sequences used for correlation.

maximum common time period (3405 BC–AD 1885; T = 5,290 yr).

As the primary ^{14}C spectrum is 'red' with a slope, using a power law fit, with spectral index approximately -1, and the region of the spectrum of interest here encompasses periods longer than about 80 yr, aliasing is not significant. Filtering and corruption by splining have been studied using Monte Carlo tests and synthetic sequences whose spectra satisfy the 'red' slope characterizing the $\Delta^{14}C$ spectrum. The test sequence realizations are generated using sinusoidal sequences of decreasing mean amplitude, normally distributed, and with random phase[11], upon which may be superimposed signals of specific intensity. These tests show insignificant corruption of the data for periods in excess of several times 10 yr.

The PSDs are computed using the maximum entropy method (MEM)[12,13], although we have confirmed major spectral features using the less constrained Yule–Walker (YW) algorithm[14,15] and also the Singleton fast Fourier transform (FFT)[16]. Both the MEM and YW algorithms involve all-pole filter models which are considered most suitable for data where the major features are spectral lines. Figure 1 shows the PSDs for both the La Jolla $\Delta^{14}C$ and the Campito Mountain bristlecone pine tree-ring sequences. Both have major features in common. As noted the periods of the lines should be regarded as approximate, because the pole positions in the autoregressive (AR) filter are somewhat dependent upon detailed properties of the sequences. (This is thought to be due to the line splitting phenomenon which results in peak shifting depending upon signal to noise ratio[17]. Its correction is under study and is expected to refine the periods reported here.) The La Jolla $\Delta^{14}C$ series has been previously investigated by Kruse[3] and in greater detail by Neftel *et al.*[8] using the standard FFT. The prime purpose of these investigations was to demonstrate that the secular $\Delta^{14}C$ variations are not random and hence cannot b caused by experimental errors. Moreover these investigatior show that the $\Delta^{14}C$ time series contains cyclic features, in pa ticular a prominent spectral line of about 200-yr period. Ou analysis confirms these earlier results in all their details. Becau of its ubiquity, we have centred attention on the 200-yr peric as a key marker of a solar interrelation between the sequenc reported here. Thus the appearance of the 200-yr period in th ^{14}C record, repeated in the tree-ring record, strongly suppor the contention that this solar-based signal is reflected in th growth rate of wood in the bristlecone pines.

The PSDs have normalized amplitudes with the highest pea in each spectrum set to unity for convenience. Table 1 gives th periods of selected lines for each of the two spectra. Althoug MEM estimates are thought to have better intrinsic resolutio than $\Delta f = 1/T$, FFT estimates are conservatively rated at Δf $6/T$. The actual MEM resolution is possibly less than that give above, since MEM carries intrinsic filtering depending inverse upon order; very approximately the MEM frequency resolutic is optimistic by perhaps a factor of 3–4. This asymptotic lim is also given by Ulrych and Bishop[13] based on an analysis Kromer[18]. Thus $\Delta f_r = 2.3\times10^{-4}\,yr^{-1}$ for the bristlecor sequence and $\Delta f_c = 1.9\times10^{-4}\,yr^{-1}$ for La Jolla, assuming r filtering so that $(0)T/20$ independent degrees of freedom a available. Combining the two gives an approximate value $\Delta f_s = 4.2\times10^{-4}\,yr^{-1}$, but more probably greater than $10^{-4}\,yr^{-}$ Inspection of Table 1 discloses that of the lines tabulated, thr pairs differ in frequency by $10^{-4}\,yr^{-1}$, one pair by $3\times10^{-4}\,yr$ and the two high frequency pairs by 7–$8\times10^{-4}\,yr^{-1}$. Thus majority of the line pairs tabulated lie approximately within better than the estimated resolution, and the two exceptio are within two resolution elements.

The calculations reported here have been repeated for th $\Delta^{14}C$ sequence from the Arizona workshop, but for brevity v report only that the agreement is qualitatively reasonable. A a final test we have also compared the La Jolla $\Delta^{14}C$ sequen with a tree-ring growth sequence of limber pine from Mou San Gorgonio in Southern California. The 100- and 200-yr lin match closely; those at longer periods (including the very stro line at 500 yr in the limber pine spectrum) probably correspo to the two long periods in the two ^{14}C spectra.

Note also that these time sequences are statistically no stationary. For a certain period within the full La Jolla reco the 200-yr line disappears as has been pointed out previou by Neftel *et al.*[8], although the 200-yr line is strong before a after this period. Thus the record used for the work report here should be regarded as an integrated composite of spect response over the entire time period examined.

An independent verification of the existence of a correlati between the La Jolla $\Delta^{14}C$ sequence and the BCP ring grow

Frequency and period of some selected major lines in the ^{14}C a bristlecone ring growth spectra. The two right-hand columns are t period resolution, estimated from the sequence length.

sequence is obtained by a narrow band moving window cross-correlator operating jointly on the two sequences. The two time domain sequences are first Fourier transformed, yielding the complex Fourier coefficients. The fundamental resolution in frequency is defined as follows: as the length of the sequences, $T = 5{,}290$ yr, the frequency resolution, $\Delta f = 1/5{,}290\ \mathrm{yr}^{-1}$. The Nyquist frequency, f_N, is half the final adjusted sampling frequency of $10\ \mathrm{yr}^{-1}$, so the number of spectral estimates $n = f_N/T$. We apply a simple narrow-band filter consisting of a linearly tapered window of full width $7/20\ \mathrm{yr}^{-1}$. This triangular window provides imperfect but reasonable suppression of side lobes. Since there are five non-zero weights (1/3, 2/3, 1, 2/3, 1/3) in this filter, it weights the ends of the sequence asymmetrically. For this reason application of the filter is restricted to those spectral estimates lying in the frequency interval $1/1{,}770 < f < 1/90\ \mathrm{yr}^{-1}$. This eliminates the two lowest and highest frequency estimates.

This procedure yields a set of spectra encompassing only a very narrow band of frequencies in accordance with the discussion just given. Inversion of these spectra into the time domain thus provides two subsets of sequences, one for $\Delta^{14}C$ and the other for bristlecone pine growth rings. We now correlate these in pairs corresponding to each frequency estimates. Such a narrow banded correlation exhibits time lags which may be interpreted as phase lags over narrow frequency intervals. Further, these lags are relatively independent of the coherence. We now choose those lags corresponding to the peak value of coherence for each of the narrow-band sequence pairs. The correspondence between lag and phase with varying frequency yields the phase-frequency relation shown in fig. 1. This figure indicates a continuously varying phase with increasing frequency. The variation in phase exceeds that which could be assigned to reservoir effects, those being limited to a lag of $\pi/2$.

Stuiver[2], for the AD centuries investigated by him, reports spectral features in his ^{14}C production rate curves for the periods $T = 126$–141 and 185–218 yr at the 2σ confidence level or better. Assuming his smoothed FFTs have $\Delta f = 1/15\ \mathrm{yr}^{-1}$, then the 200-yr line is detected; the 120-yr line is less certain, lying slightly outside his lower period window. However, the correlation (of very low confidence) between White Mountain trees and the $\Delta^{14}C$ record exhibits zero lag. Since coherence depends on bandwidth, the independent test for existence of a meaningful relative phase which we use is preferred. The credibility of a detectable phase is checked independently of MEM though supported by calculations using a two channel cross-spectral MEM estimator. We believe that further work is required to interpret the phase relation, but it can be said that its detection is qualitatively consistent with the comparison of the $\Delta^{14}C$ and BPC ring growth auto-spectra.

The relation between $\Delta^{14}C$ and solar activity is well established, though many details are poorly understood. The detection of spectral lines in the bristlecone pine growth ring spectra at periods commensurate with those in the $\Delta^{14}C$ spectra implies that the $\Delta^{14}C$ detection of solar signals is repeated in the ring growth of the Campito Mountain bristlecone pines.

The similarity between the $\Delta^{14}C$ record and the growth record of the Campito Mountain bristlecone pine suggests that a forcing function is present which mediates both the atmospheric ^{14}C level and tree growth. The expectation is that the ^{14}C uptake by trees will lag growth on the premise that growth is a short term response to climate, whereas atmospheric and oceanic reserviors contribute a frequency dependent lag to the net atmospheric ^{14}C budget[19]. Since the two effects discussed here appear correlated, by a process of elimination, the Sun is an obvious candidate for the source of the variations, though expressed through widely differing 'channels', that is, hydromagnetic in the case of ^{14}C and an as yet poorly understood mechanism in the case of tree growth. Further work, especially in regard to the very complex problem of the relative phase, may aid in clarifying the mechanism(s).

As there is a strong stochastic element in the data used for this analysis, the results are fundamentally probabilistic in nature and cannot be assigned a numerically deterministic certainty. This also has the effect that the actual signal strength, for what are generally to be regarded as threshold signals, has a probabilistic distribution and can attain larger or smaller values than measured, with the mean favouring the larger. Corrections for this effect have not been considered here but would have the general effect of increasing the true signal levels above those inferred from measurement[20]. Lastly, because phase is much more sensitive to noise corruption than is amplitude, details of the relative phase should be regarded as tentative.

We thank C. W. Stockton for providing the bristlecone and limber pine tree ring width sequences, T. W. Linick for the La Jolla $\Delta^{14}C$ data and to P. E. Damon for providing the workshop sequence. Programming was carried out by T. Trebisky and by L. D. Smith. CPS was supported by grant ATM-8308378 from the NSF Solar-Terrestrial Program.

Reconstruction of precipitation history in North American corn belt using tree rings

T. J. Blasing & Daniel Duvick

Environmental Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37830, USA

Tree-ring-based reconstructions of past climate have proved useful for evaluating hydrological statistics calculated from the shorter observational record of climate[1], and particularly for analysing past patterns of drought in the western USA[2]. The independently verified climatic reconstructions obtained here provide a significant contribution to a reliable data base for evaluation of climatic changes on time scales of decades to centuries. Fifteen tree-ring chronologies were developed from specimens of drought-sensitive white oak (*Quercus alba*), many over 300-yr old, in the western part of the North American corn belt. Verification statistics indicate reliable reconstructions of annual precipitation for the two-state area of Iowa and Illinois can be obtained back to 1680 from these chronologies. This extends the network of confirmed drought-sensitive tree-ring chronologies well into the central USA, and provides encouragement for further expansion of the tree-ring chronology network into the North American grain-belt region.

Tree rings have been used to reconstruct past climate in several regions including the western USA[2,3], western Canada and Alaska[4,5], the eastern USA[6,7], and the British Isles[8]. Stockton and Meko[2] reconstructed a 270-yr drought history of the western USA, which contained some evidence of a 22-yr Hale sunspot cycle[9]. Their study region extended into the central USA, but their tree-ring data base was weak there, including only a few sites on the periphery of the North American grain-belt region. Furthermore, the climatic information content of

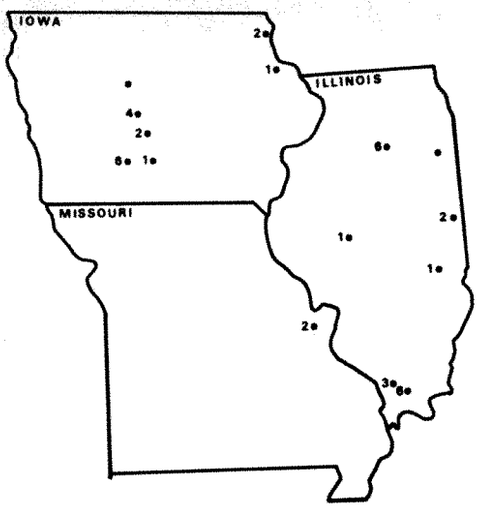

Fig. 1 Site locations of trees and number of trees at each location which date back to at least AD 1680. One site in Iowa and one site in Illinois had no trees that old, but all sites had at least one tree dating back to 1686. Some younger trees from each of the sites were also used in the reconstruction.

the ring-width chronologies from the central United States had not been verified.

Since that study appeared[2], we have published[10] preliminary results, in which the state average annual precipitation for Iowa was reconstructed back to 1680 using three tree-ring-width chronologies from the central part of the state. Our verification results encouraged further investigations leading to the more extensive network of tree sites used in this study (Fig. 1).

Usually two cores, each 4 mm in diameter, were extracted at breast height from opposite sides of each tree sampled. Ring widths from each core were converted to ring-width indices[11] using spline functions to prefilter non-climatic variance due to gradual changes in tree age, competitive status, and so on[12]. Ring-width indices of all cores at all sites in each state, Iowa and Illinois, were averaged for each year (with the Missouri site data included in the Illinois state average), and the two statewide series were averaged to form a regional ring-width-index series. This was used as the predictor variable in linear regression to estimate annual precipitation amounts averaged for the two-state area (Iowa and Illinois). In this study, annual precipitation was computed from August of the preceding year through July of the year corresponding to ring formation. This coincides with the 12-month period for which these tree rings best reflect total precipitation amounts, from the end of the preceding growing season to the end of the season in which the ring is formed[10]. Ring-width data from 1920 to 1980, and the corresponding annual precipitation data as defined above, were used to calculate the regression coefficients. State average-precipitation data available for both states since 1878 [13] were used for independent verification of precipitation estimates up to 1919.

The correlation coefficient between actual and estimated precipitation values was +0.79 for the period 1920–80, and +0.86 for the independent period. For comparison, when annual (August–July) precipitation data at Springfield, Illinois, and Des Moines, Iowa, were averaged, the correlation between that series and the two-state averages for the period 1920–80 was +0.89. All of these are significant well beyond the 99% confidence level, even after first-order autocorrelations (always below +0.25) were accounted for[14]. For the independent data (1878–1919) the reduction of error, RE, was +0.66. The RE is described by Fritts *et al.*[3] as "a most rigorous verification statistic". It is, in some ways, analogous to the so-called explained variance, but its range extends from $-\infty$ to +1, and any positive value indicates some information in the reconstruction[3]. Precipitation is often noticeably underestimated for extremely wet years, presumably because moisture is not limiting to growth[10]. Thus, precipitation estimates for normal and dry years are often more accurate than the overall statistics indicate. In this case, the RE increased to +0.76, although the correlation coefficient remained at +0.86, when one-third of the years (14 yr) having the highest estimated precipitation values were removed from the independent data set. The overall accuracy and reliability of these reconstructions of past precipitation amounts, as measured by the above statistics, are as great if not greater than any reported to date.

The reconstructed annual precipitation since 1680 is shown in Fig. 2*a*. No droughts appreciably worse than the 'dust bowl' of the 1930s are indicated, although there apparently were several droughts of roughly equal severity. The reconstructions show no long-term changes such as might occur if the precipitation there were linked to Northern Hemisphere temperature trends[15]. This is also true of the (unfiltered) actual precipitation series which began in 1878 (Fig. 2*a*). Droughty conditions are apparent beginning in the mid 1880s when the Northern Hemisphere was relatively cool[15], and in 1816 when the 'year without a summer' occurred in the northeastern United States and adjoining Canadian provinces[16]. However, the 'dust bowl' drought of the 1930s coincided with one of the warmest periods in the last century and probably one of the warmest periods in the span of our reconstructions which extend about two centuries back into the Little Ice Age[17,18]. Overall, drought in the western corn belt appears to have been about equally probable during the relatively warm and cool periods of the past three centuries. With acknowledgment to projections of increased droughtiness for a CO_2-induced climatic warming[19], our reconstructions indicate that droughts comparable with those of the 1890s and 1930s afflicted the Iowa–Illinois region at various times over the past three centuries and, therefore, should be expected to continue to do so even if no further warming occurs.

Stockton and Meko[20] analysed tree-ring data from our sites in central Iowa and found evidence of a 22-yr cycle. However, the cycle was not persistent throughout the period of record. It seemed to be strongest since about 1890 and was not evident before 1800. The 10-yr moving averages in Fig. 2*b*, based on

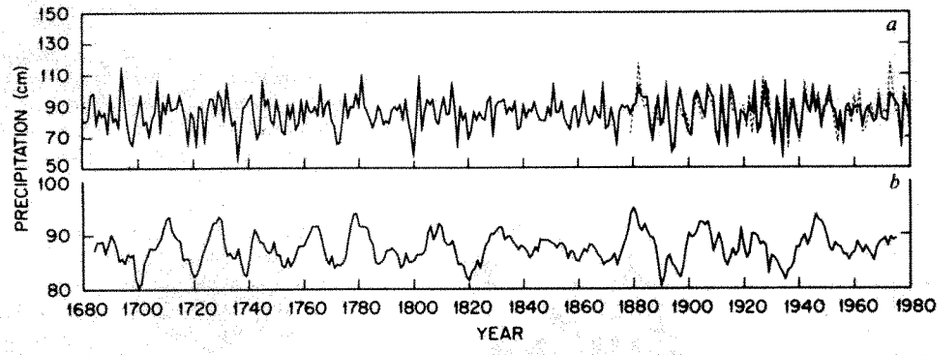

Fig. 2 *a*, Reconstructed annual (August–July) precipitation for Iowa–Illinois as obtained from the regression equation: $y = -2.788 + 90.756\,x$, where y is the precipitation estimate for a particular year and x is the regional ring-width index for the corresponding year. Actual values including independent data are indicated by the dashed line. When this equation, derived using data from young and old trees, was applied to reconstruct precipitation from only the cores dating back to 1680, the RE statistic corresponding to +0.66 in the text changed negligibly to +0.68. *b*, The 10-yr running means of the reconstructions plotted for the fifth year of each 10-yr sequence.

the data now available, suggest a cycle of about 20-yr before 1800. That may be at least partially an artefact of the frequency–response function of the moving average, but the reconstructed drought around 1720, for example, in Fig. 2*b* is much more pronounced than in the 10-yr moving averages presented earlier[10] which were based only on chronologies from central Iowa. It has been suggested that a tendency for drought to occur about every 20 yr may be due to combined effects of the Hale solar cycle of about 22 yr and the regular lunar-tidal cycle of 18.6 yr (refs 21, 22).

Reconstructions of past climate provide an extended data base for formulating or testing hypotheses about possible causes of climatic change (such as solar and lunar cycles), and for evaluating or recalculating probabilities of climatic events (such as drought) calculated from the shorter instrumental records. This work shows that excellent reconstructions of annual precipitation, for at least three centuries, are possible for portions of the North American grain belts.

Elemental constituents of atmospheric particulates and particle density

Akiyoshi Sugimae

Environmental Pollution Control Center, Osaka Prefecture, 3-62, 1-chome, Nakamichi, Higashinari-ku, Osaka 537, Japan

Atmospheric particulates are expected to be formed from materials of various densities. Particle motion in the atmosphere is characterized by the product of the density multiplied by the diameter squared. For studies of source characteristics, atmospheric transport processes and removal rates of atmospheric particulates, accurate knowledge of density distribution is essential. Previous studies[1–3] indicated that the value of 1.7 g cm^{-3} for the average density of atmospheric submicrometre particles was quite reasonable. However, there are very few published data on the elemental constituent as a function of density of atmospheric particulates I report here the density distribution of Si, Fe, Mn, Zn and Cu in the atmosphere.

Atmospheric particulates were sampled either by filtration from the suspension in the atmosphere, or by collection of deposited particles as they fall out under gravitational influence, known as dustfall. Samples of suspended particulates were collected on the rooftop (about 10 m above street level) of the Environmental Pollution Control Center in a metropolitan area of Osaka, using both a conventional high-volume sampler (hi-vol) and a low-volume sampler (low-vol). The hi-vol was used to collect samples of total suspended particulates (TSPs) on 8 × 10-inch filters. The sampler is fitted in an aluminium shelter which prevents direct settling of dusts onto the filter. Particles with a terminal settling velocity in air greater than approximately 30 cm s^{-1} are excluded from the shelter[4]. The maximum theoretical particle size has been calculated to be 100 μm (particle density = 1.0 g cm^{-3}). However, collection efficiencies for large particles are quite sensitive to small changes in wind velocity, approaching angle and flow rate[5]. The upper limit of particle sizes actually collected is believed to be 15–20 μm. The Japanese Environment Agency specifies the use of low-vol for the long-term monitoring of inhalable particulate (IP) levels. Coarse particles are preliminarily separated by three cyclones installed in the sampler. The low-vol has a D_{50} (aerodynamic diameter at an effectiveness of 50%) = 8 μm and collects IPs on 48-mm diameter filter at a flow rate of 20 l min^{-1}.

The polystyrene filter (Microsorban type 99/97, Delbag-Luftfilter GMBH, Berlin) was used as the collection medium, because the filter has collection efficiencies, capacities and loading characteristics similar to the more commonly used glass fibre filter, yet has a much lower blank concentrations of trace elements[6].

Particulates which fell as a result of their own settling velocity and which were carried down with precipitation were collected in a deposit gauge. The sample collection continued for a month. After collection, water-insoluble component of dustfall was filtered off with distilled water on a polystyrene filter.

To evaluate the contribution of wind-blown soil to local atmospheric particulates, a soil sample was taken near the sampling station.

I have modified the density gradient separation technique used for the chemical speciation of Pb compounds in street dusts[7–10] and for the multi-element characterization of roadway dusts[11] and applied it to density fractionation of particulate samples collected on polystyrene filters. The use of this type of filter was a good choice because a suspension of particulate samples for the subsequent density separation was prepared by dissolving the filter material in dichloromethane. After centrifugation, the float was transferred and the residue was centrifuged in a series of dichloromethane–diiodomethane mixtures such that the density of each successive mixture was incrementally increased by 0.2 g cm^{-3}. The final centrifugation was in diiodomethane. Particulate samples were thus classified into 12 density fractions from <1.3 to >3.3 g cm^{-3}. Iron, Mn, Zn and Cu were determined in each density fraction by inductively coupled plasma–atomic emission spectrometry (ICP–AES) following acid digestion in hot aqua regia. Silicon was determined by ICP–AES after alkaline fusion. The experimental methods have been described in detail elsewhere[12–15].

The densities of the commonly recognized compounds which exist or are expected to exist in the atmosphere are as follows: SiO_2 (2.65 g cm^{-3}), Fe_2O_3 (5.24 g cm^{-3}), Fe_3O_4 (5.18 g cm^{-3}), $Fe_2(SO_4)_3$ (3.094 g cm^{-3}), MnO (5.026 g cm^{-3}), ZnO (5.61 g cm^{-3}), $ZnSO_4$ (3.54 g cm^{-3}), CuO (6.0 g cm^{-3}) and $CuSO_4$ (3.61 g cm^{-3}).

Commonsense suggests that heavy metal compounds will be present primarily associated with particles of high density (>3.3 g cm^{-3}). However, the particle density is often related to the mode of origin, composition and interaction with the surrounding vapours and with each others[16]. The density of particle formed by comminution, attrition or disintegration will resemble that of parent material. On the other hand, fine particles originating from nucleation of vapours are highly agglomerated. It is generally accepted that the density of agglomerate which includes void spaces is less than that of individual component particles.

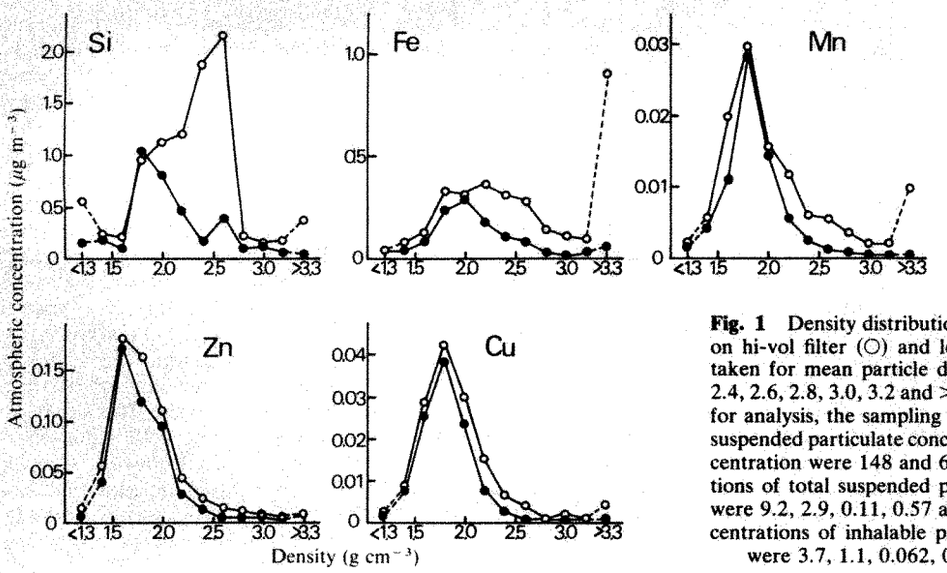

Fig. 1 Density distributions for Si, Fe, Mn, Zn and Cu collected on hi-vol filter (○) and low-vol filter (●). Measurements were taken for mean particle density of <1.3, 1.4, 1.6, 1.8, 2.0, 2.2, 2.4, 2.6, 2.8, 3.0, 3.2 and >3.3 g cm^{-3}. To collect enough material for analysis, the sampling duration was extended to 100 h. Total suspended particulate concentration and inhalable particulate concentration were 148 and 69 μg m^{-3}, respectively. The concentrations of total suspended particulates for Si, Fe, Mn, Zn and Cu were 9.2, 2.9, 0.11, 0.57 and 0.14 μg m^{-3}, respectively. The concentrations of inhalable particulates for Si, Fe, Mn, Zn and Cu were 3.7, 1.1, 0.062, 0.46 and 0.11 μg m^{-3}, respectively.

The elemental density distributions shown in Fig. 1 represent that the concentration of Si in TSPs is relatively high in the density range of 2.5–2.7 g cm^{-3}, corresponding to the density of SiO_2. Approximately 30% of Fe particles in TSPs collected by means of hi-vol are associated with particles of density higher than 3.3 g cm^{-3}. There is a general tendency for the soil-derived elements in TSPs, typified by Si and Fe, to increase in concentrations in the corresponding density ranges of the parent materials (such as quartz; haematite and magnetite). On the other hand, the concentration of Si in IPs goes through a maximum in the density range of 1.7–1.9 g cm^{-3} and another small maximum in the density range of 2.5–2.7 g cm^{-3}. The density distribution of inhalable Fe particles shows definite peak in the density range of 1.9–2.1 g cm^{-3}. Iron particles with density higher than 3.3 g cm^{-3} can account for only a few per cent of the total mass of Fe particles. It is noticeable that TSPs and IPs display quite different density distributions with respect to Si and Fe particles, which are generally present as coarse particles in suspended particulates[17–24]. The low-vol used for this study is limited to the collection of particles which have aerodynamic diameters <8 μm. The results suggest that the low-vol is relatively less efficient for collecting atmospheric soil particles existing as coarse particles in the atmosphere.

The presence of Si and Fe particles with densities less than those of parent materials is attributable partially to the presence of soil agglomerates with low apparent densities[25,26] and partially to the presence of empty spheres, known as cenospheres and plerospheres[27–29]; both spheres are formed from a particular combustion.

Volatile (chalcophilic) elements such as Zn and Cu are concentrated in low-density fractions which seem to consist of carbonaceous matter judging from their black colour and microscopic observation. In the density distributions of Zn and Cu, only one peak is observed in the density range of 1.5–1.7 and 1.7–1.9 g cm^{-3}, respectively. It is also notable that the density distributions of Zn and Cu do not differ appreciably between hi-vol and low-vol sample. The densities of Zn and Cu compounds are anticipated to be higher than 3.3 g cm^{-3} because the likely compounds of these elements in the atmosphere have the bulk densities, being higher than 3.3 g cm^{-3}. Nevertheless, Zn and Cu particles with the density higher than 3.3 g cm^{-3} can account for only a few per cent of total mass of Zn and Cu, respectively. This is probably because these elements are capable of being volatilized in high-temperature, anthropogenic processes. And fine particles originating from volatilization grow by condensation and coagulation to form agglomerates with low densities.

In the case of Mn particles collected on hi-vol filter, the density distribution shows two maxima, one for particles with density of the 1.7–1.9 g cm^{-3} range and the other for particles with

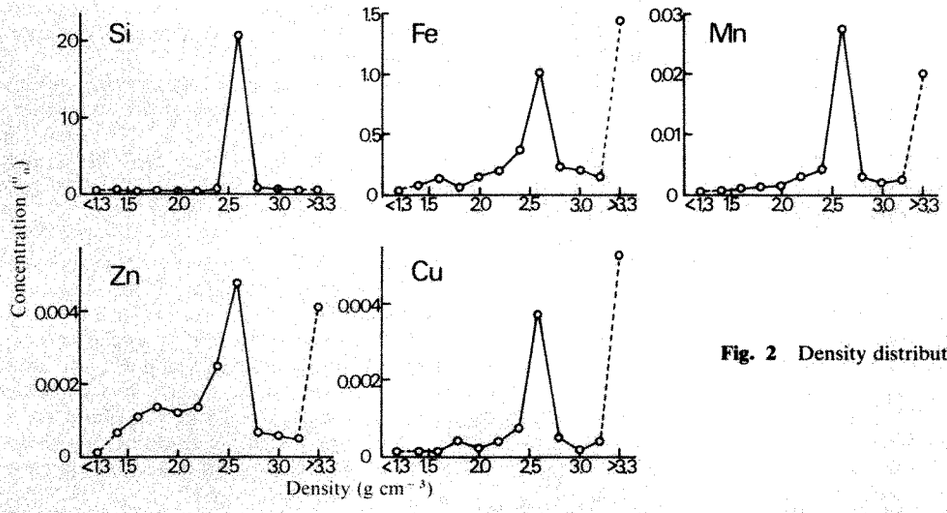

Fig. 2 Density distributions for Si, Fe, Mn, Zn and Cu in soil.

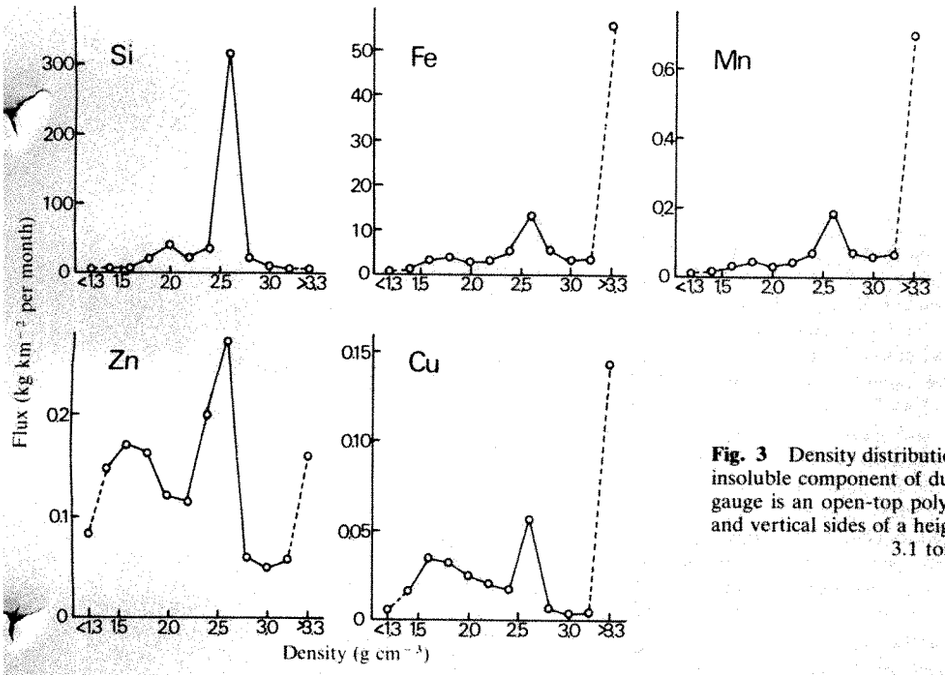

Fig. 3 Density distributions for Si, Fe, Mn, Zn and Cu in water-insoluble component of dustfall collected in a deposit gauge. The gauge is an open-top polyethylene cylinder of diameter 105 mm and vertical sides of a height of 215 mm. The flux of dustfall was 3.1 ton km^{-2} per month.

density higher than 3.3 g cm^{-3}. The density distribution of Mn particles in IPs favours low density. Manganese shows lower volatility than chalcophilic elements and is volatilized in a lesser extent in the high-temperature processes. However, low-density components are probably introduced into the atmosphere after being volatilized. The presence of dense particles (>3.3 g cm^{-3}) in TSPs suggests that abrasional processes such as crustal weathering are also the sources of atmospheric Mn particles.

In urban area, soils, street dusts, construction dusts, and so on should be efficient sources of coarse particles, most of which will rapidly fall out near their sources, but some of which should suspend as atmospheric particulates. The density distributions of Si, Fe, Mn, Zn and Cu in soil samples are shown in Fig. 2. The maximum value was found for Si in the density range of 2.5–2.7 g cm^{-3}, corresponding to the density of SiO_2. However, all elements with the exception of Si show two definite peaks in the density distributions at the density ranges of 2.5–2.7 and >3.3 g cm^{-3}. The presence of particles with density >3.3 g cm^{-3} would be explained by the presence of these elements as oxides. However, we are unaware of any crustal materials, containing these elements, with the density near 2.6 g cm^{-3}. Although the mechanisms responsible for the low density are not yet understood, the presence of these low-density particles would be explained by the presence of coarse SiO_2 particles which are coated with submicrometre platelets containing these elements. The particles associated with the density ranges of 2.5–2.7 and >3.3 g cm^{-3} can be characterized by the natural sources such as wind-blown soil dusts. The soil particles floated into the atmosphere are likely to give additional peaks at the density ranges of 2.5–2.7 and >3.3 g cm^{-3}. The elemental density distributions of suspended particulates are completely different from those of soil. However, the density distributions of Fe and Mn in TSPs show a gradual slope in the density region around 2.6 g cm^{-3}, and imply the presence of soil-derived Fe and Mn particles.

For soil particles, gravitational fallout is an important removal mechanism. The elemental density distributions for the water-insoluble component of dustfall, illustrated in Fig. 3 are essentially similar to those for the soil. The matrix material of dustfall is considered to be composed primarily of soil-derived materials. However, the low-density fractions of dustfall seem to consist of carbonaceous materials judging from their black colour. The density distributions of chalcophilic elements Zn and Cu show a broad peak near the density of 1.6 g cm^{-3}, indicative of anthropogenic sources, although the concentrations are still high in the density ranges of 2.5–2.7 and >3.3 g cm^{-3}.

Even though the most serious criticism of this technique is that the heavy liquids used for the density gradient separation would attack atmospheric particulates dissolving out some of the tarry matter and disagglomerating some clusters of particles, the technique is the only way to fractionate atmospheric particulates within the critical particle density range and provide valuable qualitative information on the physicochemical characteristics of atmospheric particulates. Until more quantitative techniques are developed, most quantitative tests for the formation and transport mechanisms for atmospheric particulates must rely on the concentration versus particle density data as well as on the concentration versus particle size data.

Photochemical production of carbonyl sulphide in marine surface waters

R. J. Ferek & M. O. Andreae

Department of Oceanography, Florida State University, Tallahassee, Florida 32306, USA

Carbonyl sulphide (COS) has been proposed as the major source of the stratospheric sulphate layer in times of low volcanic activity[1] because of its long tropospheric residence time[2], its uniform distribution in both the Northern and Southern Hemispheres[3], and the lack of knowledge of any significant sinks except photodissociation in the stratosphere[4]. Known sources of COS include biomass burning[5], volcanoes[6,7], salt marshes[2,8], fossil fuel combustion[9], and oxidation of atmospheric CS_2 (refs 10, 11). Also, recent measurements[12–14] have shown the surface oceans to be a source of COS. The total flux to the atmosphere from these known sources is substantially greater than the flux to the stratosphere needed to maintain the sulphate layer[10]. Thus questions remain about the sources and sinks of COS, and we have now performed a series of experiments in nearshore ocean and estuarine waters to investigate further the oceanic source of this gas. Dissolved COS in near-surface waters was found to be supersaturated with respect to atmospheric COS, and the dissolved concentrations varied diurnally with light intensity. Similar behaviour has been observed by other investigators for carbon monoxide, which is produced photochemically in surface seawater[15]. Furthermore, COS production appears to be independent of salinity, photosynthetic activity and microbial activity, and is probably the result of photooxidation of organic matter. COS was produced in the laboratory by UV-irradiation of seawater and solutions of several biochemically relevant organosulphur compounds.

Measurements of both atmospheric and dissolved COS were performed using an instrumental system described in detail elsewhere[14]. For air measurements, a small volume (300 cm^3) of ambient air was passed through a tube immersed in liquid nitrogen to trap out gases which were then separated on a chromatographic column and analysed by a flame photometric detector for sulphur. For dissolved COS, a closed volume of air was cycled through a gas bubbler in a glass column containing rapidly exchanging seawater until the air was equilibrated with the dissolved gases in the seawater. The equilibrated air was then analysed as before and compared with the ambient air concentration to obtain directly the COS saturation ratio (SR) in the water (that is $[COS]_{equil\ air}/[COS]_{amb\ air} = SR$). Liquid concentrations can be calculated from the saturation ratio using Henry's law as follows:

$$[COS]_{liq} = \frac{[COS]_{amb\ air}}{h} \times SR$$

where h is the Henry's law constant for COS in seawater[16].

Initial measurements of the diurnal behaviour of dissolved COS were performed at the FSU Marine Laboratory located at Turkey Point on the north coast of the Gulf of Mexico south of Tallahassee, Florida. A continuous supply of seawater was obtained from the seawater circulation system with intake ~650 m offshore in 0.5–1.5 m of water. The residence time of water in the system was ~45 min. Figure 1 shows the results of two sampling periods at the Marine Laboratory. COS supersaturation shows a large diurnal cycle with peaks occurring during mid to late afternoon. No effect of tide (semidiurnal at this site) was observed.

Further measurements of COS saturation in surface waters were made during a cruise of the RV *Cape Hatteras* to Chesapeake Bay (28 March–3 April 1983) and Delaware Bay (4–8 April 1983). Seawater was obtained from the ship's continuously pumping seawater system with intake located 3 m below the surface. Ambient air was drawn through a Teflon

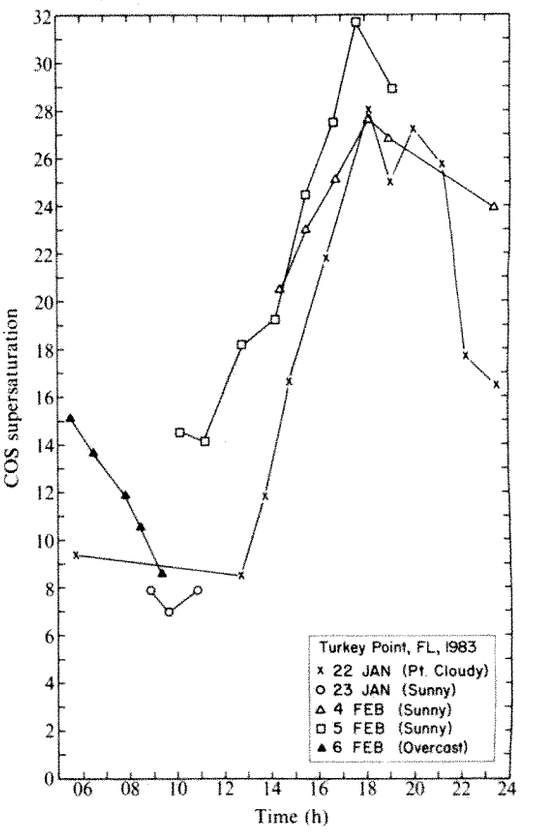

Fig. 1 Diurnal variation of COS in surface seawater measured at FSU Marine Laboratory, Turkey Point, Florida (northeastern Gulf of Mexico). The data are expressed as supersaturation ratio, that is, the ratio between the actual concentration in seawater and the concentration in equilibrium with ambient air.

tube (6.4 mm i.d.) which extended from the top of the mast to the laboratory. Figure 2 shows the diurnal behaviour of COS over a range of locations in both bays together with the hourly totals of light intensity in einsteins per m^2 (T. R. Fisher, personal communication). The highest COS supersaturations occur on days when light intensity was greatest. 28 and 29 March were both north–south transects of Chesapeake Bay over the same route. Although light measurements were not available on 28 March, it was a sunny day compared with partly cloudy conditions on 29 March, hence the higher COS levels on 28 March. Measurements on 30 March, 31 March, 1 April, and 2 April were taken at stations on Chesapeake Bay at surface salinities of 24, 17.4, 11, and 12‰, respectively. The magnitude of the COS saturation is again related to light intensity with no observable effect of salinity. Some of the variation on 1 April between 1100 and 1500 h may be due to vertical mixing as indicated by a lowering of the depth of the pycnocline between those hours. Since the secchi disk transparency was only slightly greater than 1 m, an increase in vertical mixing would be expected to mix in water from below with low COS concentration. This is reflected in the lowering of the COS saturation between 1100 and 1500 h on 1 April as opposed to a continuous rise during the daylight hours as illustrated in the FSU Marine Laboratory data (Fig. 1). The 3 April measurements were made near the mouth of the Susquehanna River (surface salinity = 0.2‰) on a sunny day. The COS saturation remained low relative to the other sunny days, probably due to low light penetration into the very turbid water (secchi disk transparency = 35 cm) at this station. 4 April was a north–south transect of Delaware Bay and 5 April was a station off Cape Henlopen (salinity = 29‰). COS saturations on both days do not appear appreciably different from the earlier Chesapeake stations.

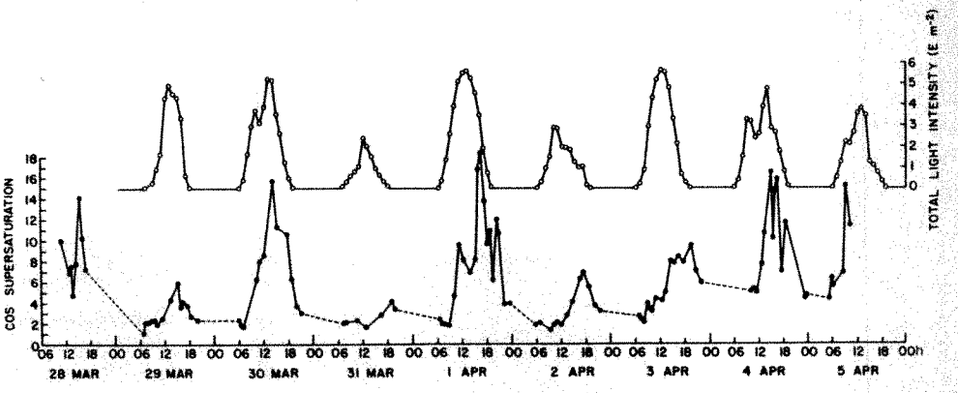

Fig. 2 COS supersaturation and light intensity measured in surface waters during cruise of RV *Cape Hatteras* in Chesapeake and Delaware Bays, spring 1983.

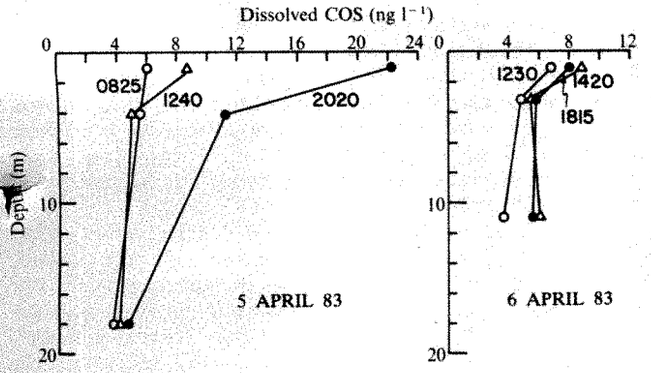

Fig. 3 Variation of the depth profile of dissolved COS concentration for two stations in lower Delaware Bay. 5 April was partly cloudy, 6 April was overcast. The time of sampling is indicated on each profile.

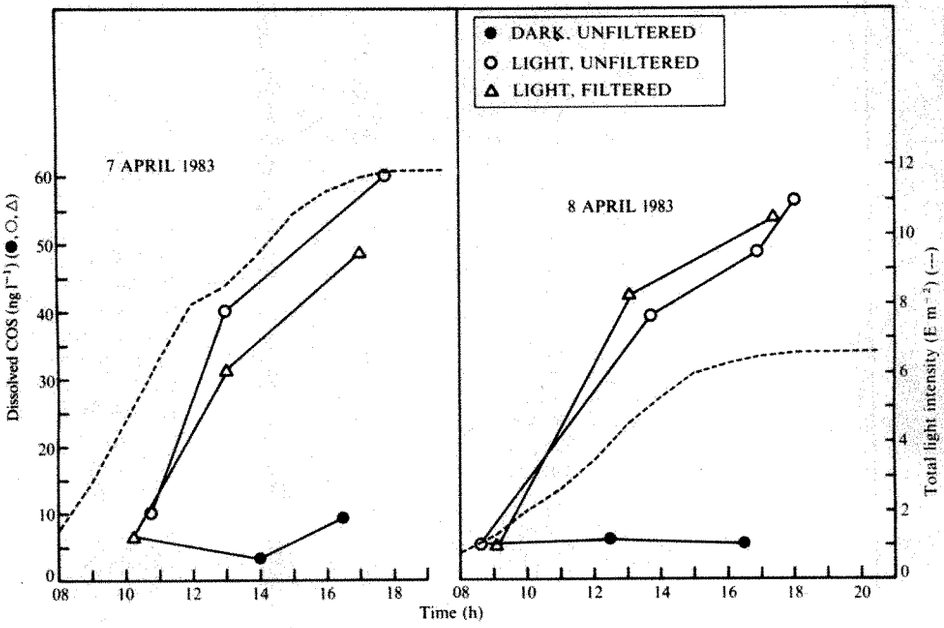

Fig. 4 Increase of COS concentration in surface seawater samples (filtered and unfiltered) incubated in light and dark bottles. The total integrated light intensity is indicated by a dotted line.

While at the Cape Henlopen station (5 April) and the 6 April station in lower Delaware Bay (surface salinity = 19‰), samples were collected at different depths by hydrocasts with 5-l Niskin bottles. 50-ml water samples were filtered through Gelman AE filters and purged with helium for 20 min in a gas stripping column with the effluent passed through a glass bead trap immersed in liquid nitrogen. Successive purges showed 20 min to be sufficient purging time to strip >90% of the dissolved COS from the samples. Figure 3 shows the results of these experiments. 5 April was a partly cloudy day and 6 April was overcast. Secchi disk transparencies at the two stations were 2.6 and 1.4 m, respectively. On both days COS at the deepest level remained fairly constant and 2–5 times lower than the surface concentrations. Diurnal variation was greatest at the surface level, indicating that production of COS was confined to the photic zone.

A final experiment to check the effect of biological activity on the production of COS was performed on 7 and 8 April. Surface samples were collected at two stations in upper Delaware Bay (salinities 7.0 and 3.4‰). One sample was sterilized by filtering through a 0.45-μm Nuclepore filter and, along with an unfiltered sample, analysed immediately by purging with He. Other filtered and unfiltered samples were placed in light and dark bottles and incubated in daylight for different lengths

of time. Figure 4 shows the results of these measurements. Also plotted are the running totals of light intensity throughout the day. The production of COS in the light bottles followed the light intensity, while dark bottles remained essentially constant at the initial COS concentration. There was essentially no difference between the filtered and unfiltered samples within the experimental uncertainty. The production of COS seems to be due to photooxidation of dissolved organic matter and thus only indirectly related to biological activity. As the 0.45-μm filter will remove all phytoplankton cells, but not all bacteria, a microbial production of COS cannot be rigorously excluded on the basis of this experiment. However, repeated irradiation of seawater with UV light from a small mercury discharge lamp ($\sim 400\ \mu W\ cm^{-2}$ of 254 nm light) in the presence of dissolved O_2, followed each time by degassing and determination of the COS produced, released COS in slowly decreasing amounts. Under the high UV intensities used, bacteria would have been killed during the first irradiation–degassing cycle and no further COS production should have taken place. UV irradiation of 100 μM solutions of several biochemically relevant organosulphur compounds (cysteine, methionine, glutathione, dimethylpropiothetin) in deionized, distilled water in the same conditions also produced substantial amounts of COS. This reaction did not occur when the solutions were stripped of dissolved O_2 by purging with He before irradiation.

Further evidence for the sea surface being a source of COS to the atmosphere can be seen in the ambient air concentrations measured at the three different locations. At Tallahassee, the mean ambient concentration of COS on 17 January, 18 January, and 18 February 1983 was $\bar{x} \pm s = 515 \pm 82$ p.p.t.v. (parts per 10^{12} by volume) ($n = 28$). This is very close to the mean tropospheric concentration of 512 ± 60 p.p.t.v. reported by Torres *et al.*[3] for a total of 346 measurements during Project GAMETAG. During the period of sampling at the FSU Marine Laboratory, atmospheric concentrations were 537 ± 59 p.p.t.v. ($n = 65$), not significantly different from Tallahassee. However, during the Chesapeake and Delaware Bays cruise, the ambient air concentration was 627 ± 84 p.p.t.v. ($n = 204$), ~20% higher than the continental and coastal concentrations, and may be due to the closer proximity to the surface seawater source. In addition, air concentrations averaged 641 ± 88 p.p.t.v. ($n = 131$) between the hours of 10 am and 8 pm and 601 ± 70 p.p.t.v. ($n = 73$) between 8 pm and 10 am.

Earlier measurements[12,14] in open ocean areas found COS saturation in surface waters averaging approximately 2.0, which results in a flux to the atmosphere of ~ 0.5–0.9×10^{12} g COS yr^{-1}. The higher saturations observed in coastal waters may make the total flux from the oceans greater than previously estimated. We are attempting to gather data from more diverse areas of the ocean to further refine our estimate of this flux.

We thank the captain and crew of the RV *Cape Hatteras* and chief scientist T. R. Fisher for their cooperation. J. T. Byrd and G. Baptist helped with sample collection. This work was supported by NSF grant ATM-8017574.

First observations of the interaction of ocean swell with sea ice using satellite radar altimeter data

C. G. Rapley*

Groupe de Recherche de Géodésie Spatiale,
18 Avenue Edouard Belin, 31055 Toulouse Cedex, France

The action of ocean waves and swell on sea ice in the marginal ice zone (MIZ) controls the size distribution of ice floes and thus affects ice dynamics and the thermodynamics of ice growth and decay. An understanding of ice processes is important because of the influence of the sea-ice cover on high latitude weather and global climate[1]. Also, long-term changes in average sea ice extent could provide a sensitive indication of climatic change if the degree of shorter term variability were better understood[2]. Previous observations of the propagation of swell within the ice pack have been limited in spatial and temporal extent[3–6]. Here we present new results from the US Seasat satellite which suggest that radar altimetry can provide a powerful means of global synoptic monitoring of the interaction between ocean and ice.

The US satellites GEOS-3 and Seasat carried pulse-limited altimeters designed for studies of the geoid and ocean surface[7]. Both instruments obtained data over regions of sea ice. The radar echoes observed were highly variable but were generally stronger and more peaked in time than those from open water[8]. Brown[9] attributes the intense component of first-year ice returns to a coherent signal from smooth ice platelets all lying at the same level amongst the floes. Robin *et al.*[10] show that the peaked component will dominate over the diffuse echo if even as little as 0.01% of the surface contributes a coherent signal. Thus, provided any small areas of new ice or calm water are exposed within the altimeter footprint, we may expect to observe a strong return, and if the sea surface between floes is flat the waveform will be highly peaked.

Figure 1 shows three examples of the evolution of on-board computed values of 'significant wave height' (SWH) and signal strength (automatic gain control, AGC) as the Seasat altimeter passed from open ocean into the ice pack. Obvious features are the step in signal strength at the ice edge (indicated by the arrows) and the greater variability of both parameters over the ice. A particularly interesting feature of the SWH data in Fig. 1*a* and *b* is the gradual overall decline to zero with increasing distance from the ice edge. It is not immediately obvious to what property of the pack ice the SWH value corresponds. An insight into the effect is provided by the altimeter waveform data which typically evolve as shown schematically in Fig. 2 (see also Fig. 1*d*, *e* of Robin *et al.*[10]). Pulse shapes just inside the ice edge (Fig. 2*a*) are often almost identical to those from the nearby ocean, although amplitudes may be as much as 10 times greater. Altimeter pulse risetimes are a measure of the height probability density function of reflecting elements at nadir, and pulse fall times depend on the slope distribution (that is, for specular reflection the maximum duration of the pulse is given by $t_m = (h/c)\theta_{max}^2$ where θ_{max} is the maximum surface slope, and c and h are the velocity of light and satellite altitude respectively). Apparently, neither distribution changes significantly across the ice edge, although the large increase in signal strength implies that the nature of the reflecting elements must alter dramatically. This may be naturally explained if most of the power returned is reflected from thin ice platelets or smooth water between floes as discussed previously. The increasing leading edge slope and more rapid decay of waveforms deeper in the pack (Fig. 2*b*,*c*) then imply a continuous reduction in the interrelated height and slope distributions of the ocean

* Permanent address: Mullard Space Science Laboratory, Department of Physics and Astronomy, University College London, Dorking, Surrey RH5 6NT, UK.

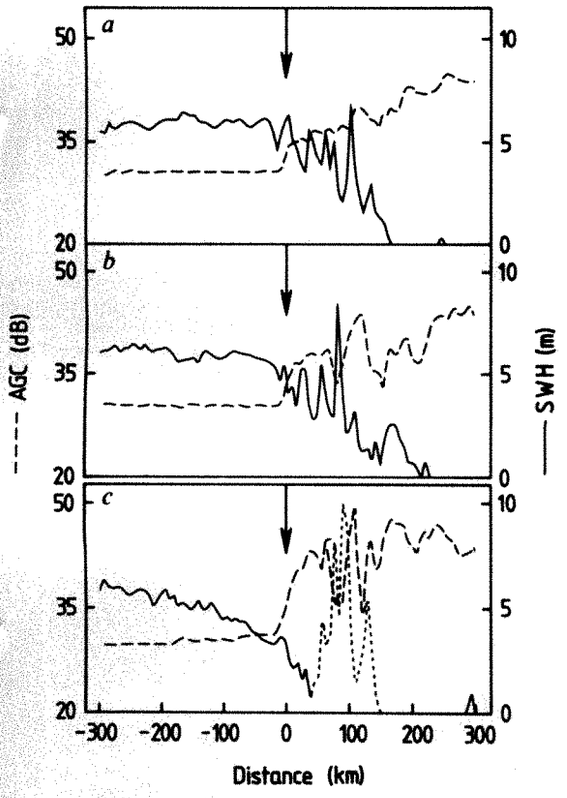

Fig. 1 Three examples of the evolution of on-board computed SWH and AGC values as the Seasat altimeter passed from ocean to sea ice. The ice edge is indicated by the arrow in each case. Note the sudden increase in AGC at the edge and the gradual overall decline of SWH value to zero. Note also the increased SWH noise within the ice pack and the poor data points, particularly in example *c*.

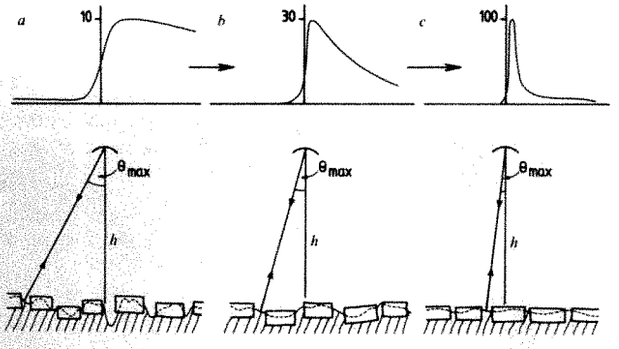

Fig. 2 The evolution of waveform shape and strength as a function of increasing distance into the ice pack. Leading-edge slopes depend on the height distribution of scatterers at nadir just as for ocean returns. Falltimes are determined by the distribution of surface slopes as shown schematically in the lower panels. Pulse strengths are relative to a value unity for a standard ocean return. Pulse shape and strength change as ocean waves and swell are damped out by the action of ice floes within the pack.

(or thin ice) surface as a function of distance from the ice edge. This is consistent with the known behaviour of ocean waves within the ice[5,6].

The relationship between pulse shape and SWH value is not straightforward. The on-board processing methods used by the Seasat altimeter were based on a standard ocean waveform model and the measured instrument performance characteristics[11,12]. An analysis of the response to non-standard pulses is complicated by interactions between all three processing loops[13]. However, an SWH output of zero was special and indicated a value less than the minimum resolvable by the instrument (~40 cm). This could only occur for pulses more peaked than an ocean return, although the degree of 'peakiness' necessary was a function of pulse risetime. Nevertheless, risetime and peakiness are partially interrelated as we have described, and we may therefore use zero SWH as a crude reference level of surface flatness.

Unfortunately, the on-board computed SWH values over sea ice suffered from increased noise and poor data points (note Fig. 1*c* in particular). The latter consist of correlated excursions of the height and SWH signals and resulted from brief attempts by the on-board tracker to follow receding bright features during transitions between areas of high and low surface reflectivity. The effect is similar to that described by Thomas *et al.*[14] for transitions across an ice front. The geographical distribution of extreme events shows a strong concentration in the vicinity of the ice edge and in areas known to be prone to polynya formation, implying an association with transitions from new or first-year ice to open water. Alternatively, 'hunting' by the on-board tracker when processing highly peaked pulses[13] could have introduced similar errors. Occurrences within the ice pack were more frequent towards the coast where AGC values were low, and may have resulted from transitions to areas of continuous ice or snow cover. Much of the contaminated data can be recovered by analysis of the altimeter waveforms but this represents a very major computing task. Thus, an exploratory investigation of swell propagation within the ice was carried out using the SWH data, recognizing its limitations. The use of a spatial resolution of ~70 km (10 point averages) and the averaging effect of adjacent groundtracks reduced the impact of data contamination on the results.

Figure 3 shows data from four successive repeats of the 3-day orbit cycle executed by Seasat during September 1978 at the time of maximum sea ice extent. The ice edge derived using an AGC threshold of 33 dB and the zero SWH contour are shown, the region between being shown as solid areas. Despite the coarse spatial resolution used, inconsistencies in the location of the ice edge occur due to motion within a 3-day cycle. These are represented by small re-entrant features. The SWH contour joins locations at which zero SWH is first encountered on entry into the ice pack. All non-zero SWH values within this contour are ignored as are occasional groundtracks obviously affected by poor data. Also shown are zones of high ocean swell (>5 m) derived using the method of Mognard[15] (see also ref. 16). The zones shown represent major storm systems. An immediate qualitative correspondence can be seen between areas in which the zero SWH contour is furthest from the ice edge and nearby zones of high swell. Furthermore, changes in the width of the band follow the temporal and spatial evolution of the swell storms. For example, the sector between 30° E and 60° W contains little swell storm activity and consistently exhibits a narrow band of swell penetration, whereas the decay of the major swell storm between 30° E and 120° E is matched by a decline in penetration distance.

The altimeter data therefore provide a means of using the ice as a detector of swell or, alternatively, the swell as a probe of the ice. The energy decay of each swell component is known to be exponential with an attenuation coefficient strongly dependent on swell wavelength and ice thickness[5,6]. The width of the band shown here also depends on the amplitude of the penetrating component at the ice edge and may be affected by the inadequacies of the SWH data as described above. Nevertheless, the observed penetration distances of up to 300–400 km are consistent with previous *in situ* measurements[3]. Detailed, quantitative studies will require analysis of the waveform data. Even so, the SWH data provide useful qualitative insights into ice properties. For example, the strong propagation of low swells into the edge features seen between 30° W and 90° W in Fig. 3*a* and at 30° W in Fig. 3*d*, implies that the ice is thin, as does their rapid spatial variability.

In an attempt to relate swell effects to ice edge growth, Fig. 4 shows a detail of ice edge changes over the four periods. A good general correlation is observed between ice edge variability and regions affected by swell, particularly in the case of the

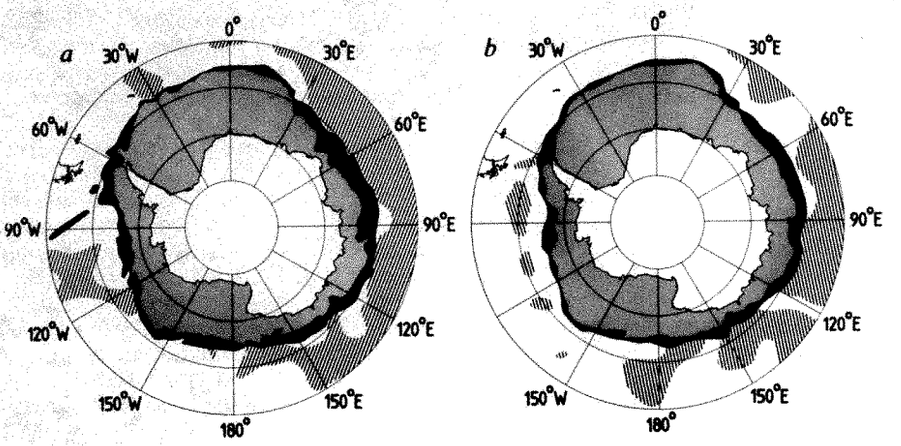

Fig. 3 Four consecutive 3-day maps of Antarctic sea ice (shaded areas) and regions of ocean swell greater than 5 m (cross-hatched areas) during September 1978. Zones of swell penetration into the ice (solid areas) derived from the SWH data contract and expand with the decline and subsequent growth of nearby ocean swell storms. Note the generally limited penetration in the region 30° E to 60° W where swell activity is low during this period, other than the feature suspected to consist of thin ice in *d*.

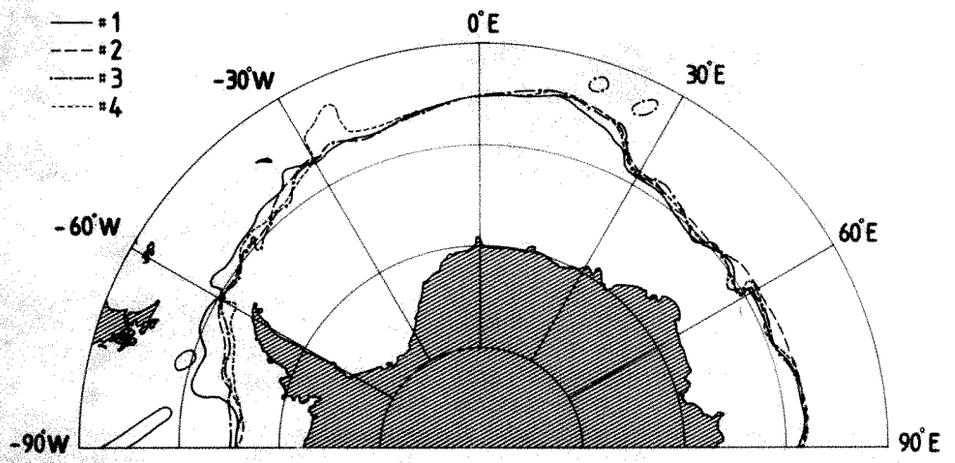

Fig. 4 Detail of the ice-edge variations over the four 3-day cycles. Greater variability occurs in regions affected by swell. Features showing the greatest changes are deeply penetrated by low-amplitude swells (see Fig. 3) implying that the ice is comparatively thin.

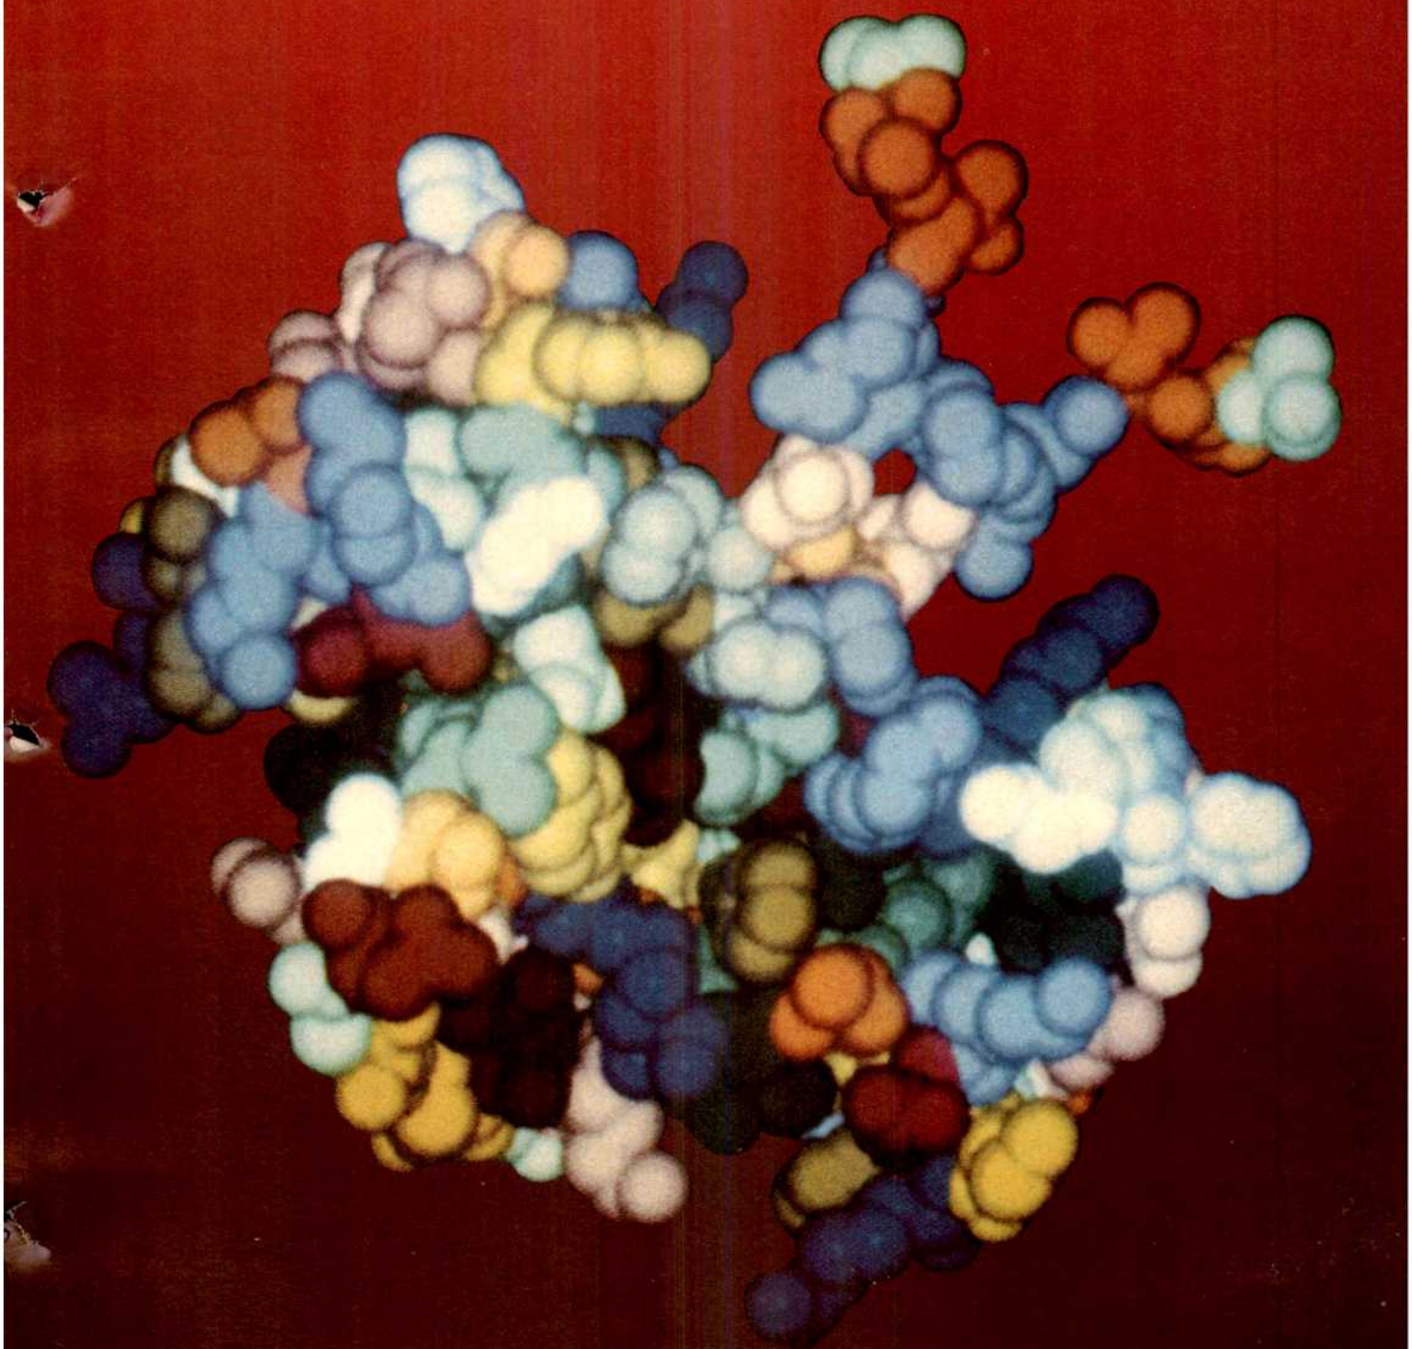
(apparently) thin ice features already noted. Keliher[17] has previously reported an association between pack ice disturbances and regions of high sea state.

We may conclude, therefore, that variations in altimeter return pulse shape provide a powerful means of monitoring swell propagation within the ice pack. Difficulties associated with the use of on-board SWH values have important implications on instrument design and data analysis procedures for future satellite altimeter missions.



I thank the Centre Nationale d'Etudes Spatiales, France for financial support and the Groupe de Recherche de Géodésie Spatiale for their hospitality and assistance. I am particularly grateful to Mr Claude Brossier for his hard work and enthusiasm in producing the data plots and to Dr Michel Lefebvre for his encouragement. I acknowledge useful discussions with Drs Nelly Mognard and Bill Campbell.

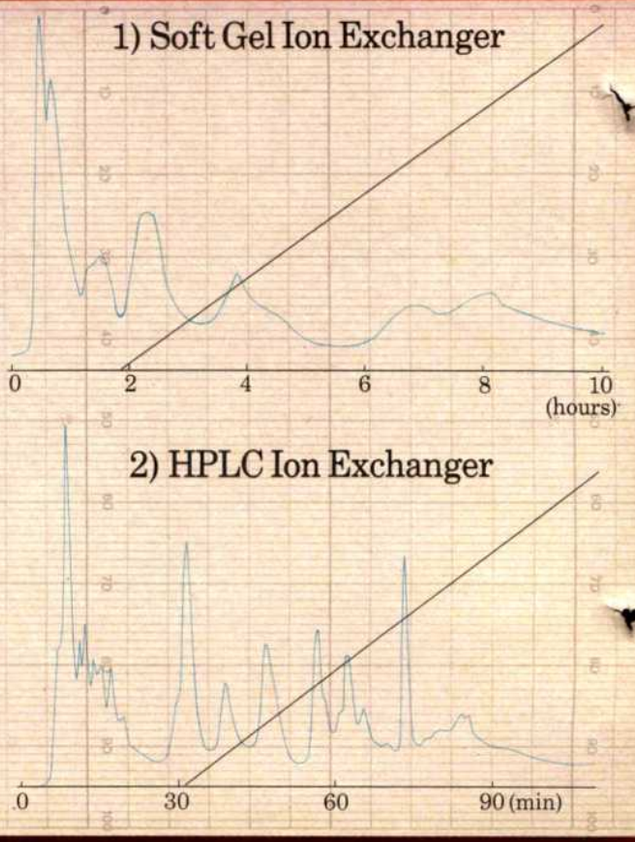
LKB
BROMMA

LKB HPLC systems revolutionize biology, biochemistry and biotechnology.



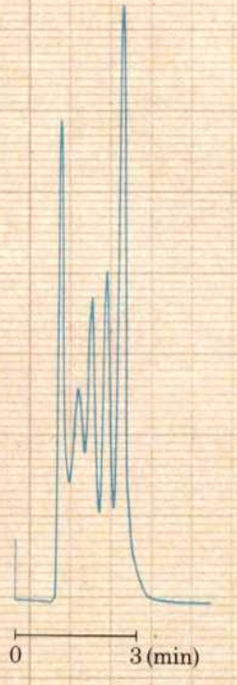
Achieve rapid, high resolution

High resolution

Sample:	Tryptic digest of aldehyde dehydrogenase
Detection:	280 nm, 1) 0.1 AUFS; 2) 0.02 AUFS
Gradient:	0—0.1 M NaCl in 0.02 M ammonium acetate, 8 urea, pH 5.0
HPLC Column:	CM, LKB 2133-200, 7.5×150 mm

Recent developments in high performance liquid chromatography have brought on a veritable revolution in the life sciences—enabling exploration far beyond the resolution limits of conventional liquid chromatography. These extraordinary improvements in resolution can be attributed primarily to the unique character of new HPLC separation media.

LKB HPLC columns are packed with rigid silica particles of approximately 1/10th the diameter of traditional soft gel media. The rigidity of these particles enables better packing than conventional liquid chromatography techniques. The smaller diameter results in more efficient fractionation, sharper peaks, increased resolving power and higher sensitivity.

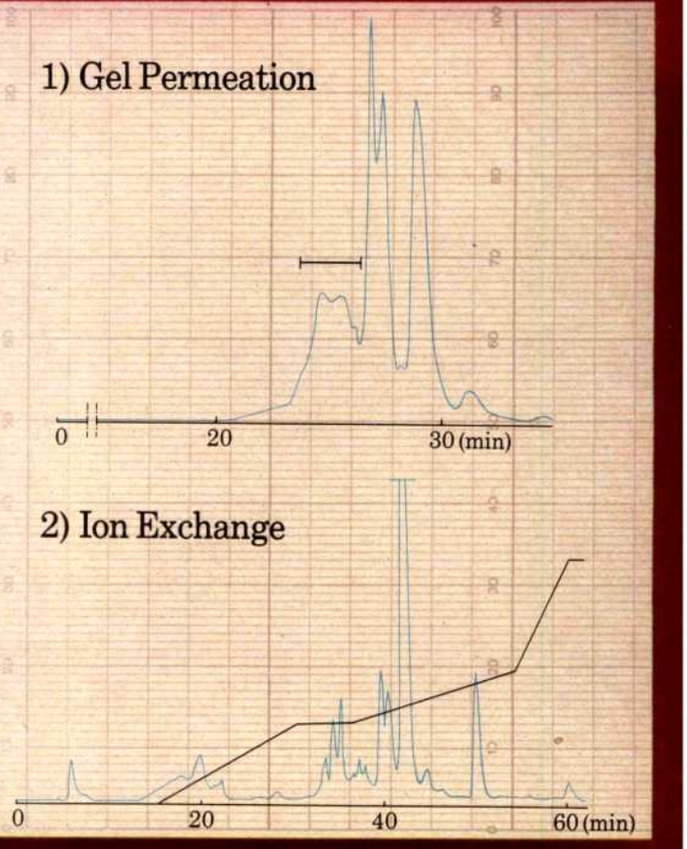


Rapid analysis

Sample:	Mixture of thyroglobulin, gammaglobulin, ovalbumin, myoglobin, vitamin B_{12}
Detection:	280 nm, 0.32 AUFS
Eluent:	0.1 M Na-phosphate buffer, pH 6.8
Flow rate:	1.0 ml/min
Column:	Gel permeation, LKB 2135-075, 7.5×75 mm

HPLC is the most rapid and efficient method available today for the fractionation of biomolecules. The HPLC separation shown here, for example, would have taken several hours by conventional soft gel chromatography! Like improvements in resolution, shorter analysis times are attributable largely to the rigidity and relatively small diameter of the HPLC media—enabling more rapid mass transfer between the stationary and mobile phases.

As a life scientist you are compelled to seek rapid methods for the fractionation of your samples. Not only are you interested in faster sample throughput, but you are also concerned about the danger to labile molecules of prolonged or drastic treatment, or the short half-life of a radioactive isotope. In addition, many conventional methods require harsh and time-consuming separation procedures. In all these cases, LKB HPLC systems are rapid and highly efficient alternatives.

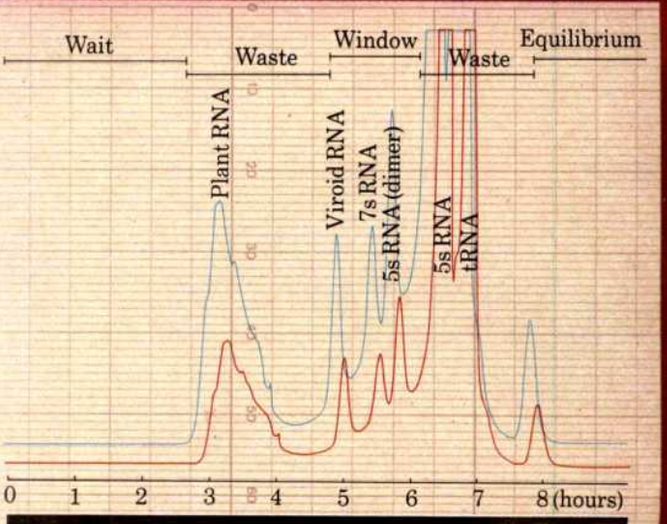


separations of biomolecules

Optimized purification schemes

Detection:	254 nm, 1) 0.5 AUFS; 2) 0.1 AUFS
Gradient:	2) 0.03—0.7 M ammonium acetate, pH 6.2
Columns:	1) Gel permeation, LKB 2135-260, 7.5×600 mm 2) DEAE, LKB 2133-100, 7.5×150 mm

By combining LKB HPLC techniques and thereby increasing the resolving power and speed of critical steps in a separation process, it is now possible to produce significant improvements in the efficiency of purification schemes. In this example, the entire separation was three times faster than conventional techniques and revealed 3—4 times as many components. An ultrafiltrate from the serum of uremic patients was first resolved by high performance gel filtration chromatography. Components in the molecular weight range 350—2000 (those which accumulate in the blood of uremic patients) were then applied to a high performance ion exchange column and resolved into 22 peaks.



Preparative capabilities

Sample:	RNA from PSTV-infected tomato leaf
Detection:	254 nm, 1.0/2.0 AUFS
Eluent:	0.01 M NaAc, 0.02% NaN_3 0.2 M NaCl, 5 mM $MgCl_2$, pH 5.0
Flow rate:	0.4 ml/min
Column:	Gel permeation, LKB 2135-465, 21.5×600 mm

Courtesy of Sänger et al, Max-Planck-Institut of Biochemistry, Martinsried

Preparative LKB HPLC systems have proven to be a highly attractive alternative to other methods commonly used to separate complex mixtures of proteins and polynucleotides.
In this example, a preparative LKB HPLC system has been used to resolve a mixture of nucleic acids with a resolution comparable to that of analytical electrophoresis. Fractions of interest were collected automatically by the LKB 2211 SuperRac fraction collector. While electrophoretic methods are the traditional choice for analytical separations of polynucleotides, the preparative application of electrophoresis suffers from drawbacks such as limited loading capacity and extraction procedures which are tedious and often result in a loss of purified material. In this example, 400 OD of viroid RNA was eluted in less than 5 hours, with a recovery of better than 90%.

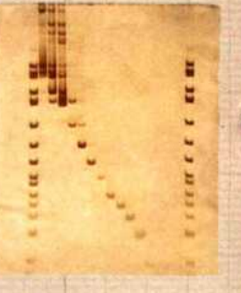
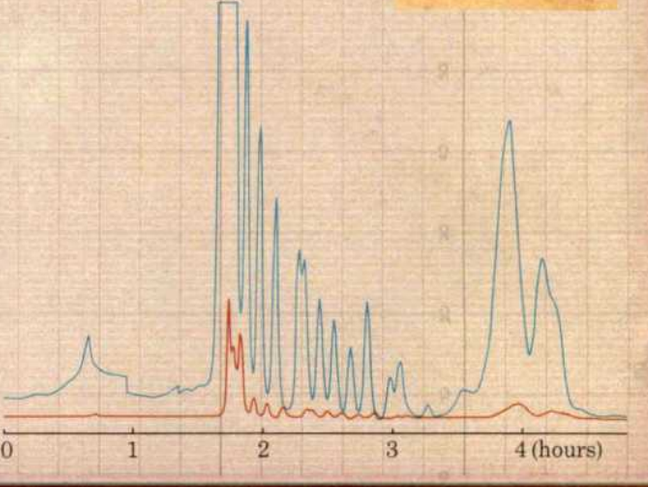
Gel Permeation Chromatography

Sample:	ϕX 174 from RBL incubated with Hinf I
Detection:	257 nm, 0.01/0.02 AUFS
Eluent:	50 mM TEAA, pH 7.0
Flow Rate:	100 µl/min
Column:	LKB 2135-460, 7.5×600 mm



Courtesy of Kruppa et al, Physiol.-Chem. Institut, Hamburg



LKB offers a wide range of analytical and preparative Blue Columns for high performance gel permeation chromatography. The column packing material, a macroporous silica particle support, has been chemically modified to provide an inert and non-adsorptive stationary phase appropriate for high resolution separations of a wide variety of biomolecules as well as for use with most commonly used buffer systems and solubilizing agents.
The calibration shown here is just one of several examples of the excellent resolution, linearity and selectivity obtainable with an LKB high performance gel permeation system.

Calibration curve prepared from the chromatogram.

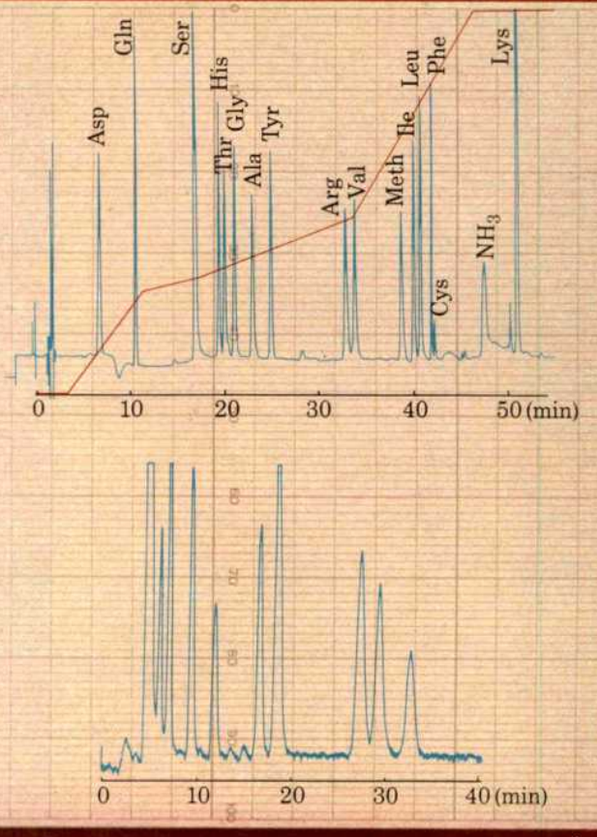
suitable for your sample

Ion Exchange Chromatography

Sample:	Trypsinogen, ovalbumin and trypsin inhibitor
Detection:	280 nm, 0.32 AUFS
Gradient:	0-0.5 M NaCl in 0.05 M Tris-HCl, pH 7.2
Flow rate:	1.0 ml/min
Column:	DEAE, LKB 2133-100, 7.5×150 mm

LKB Blue Column DEAE and CM ion exchangers can be used at high pressures and ionic strengths, and with a wide variety of buffer systems. Due to their speed, resolution and wide range of application, high performance ion exchange techniques are rapidly replacing many methods conventionally used for separation and analysis prior to protein sequencing; they are now also used to purify commercially-available proteins for enzyme assays and structural studies.

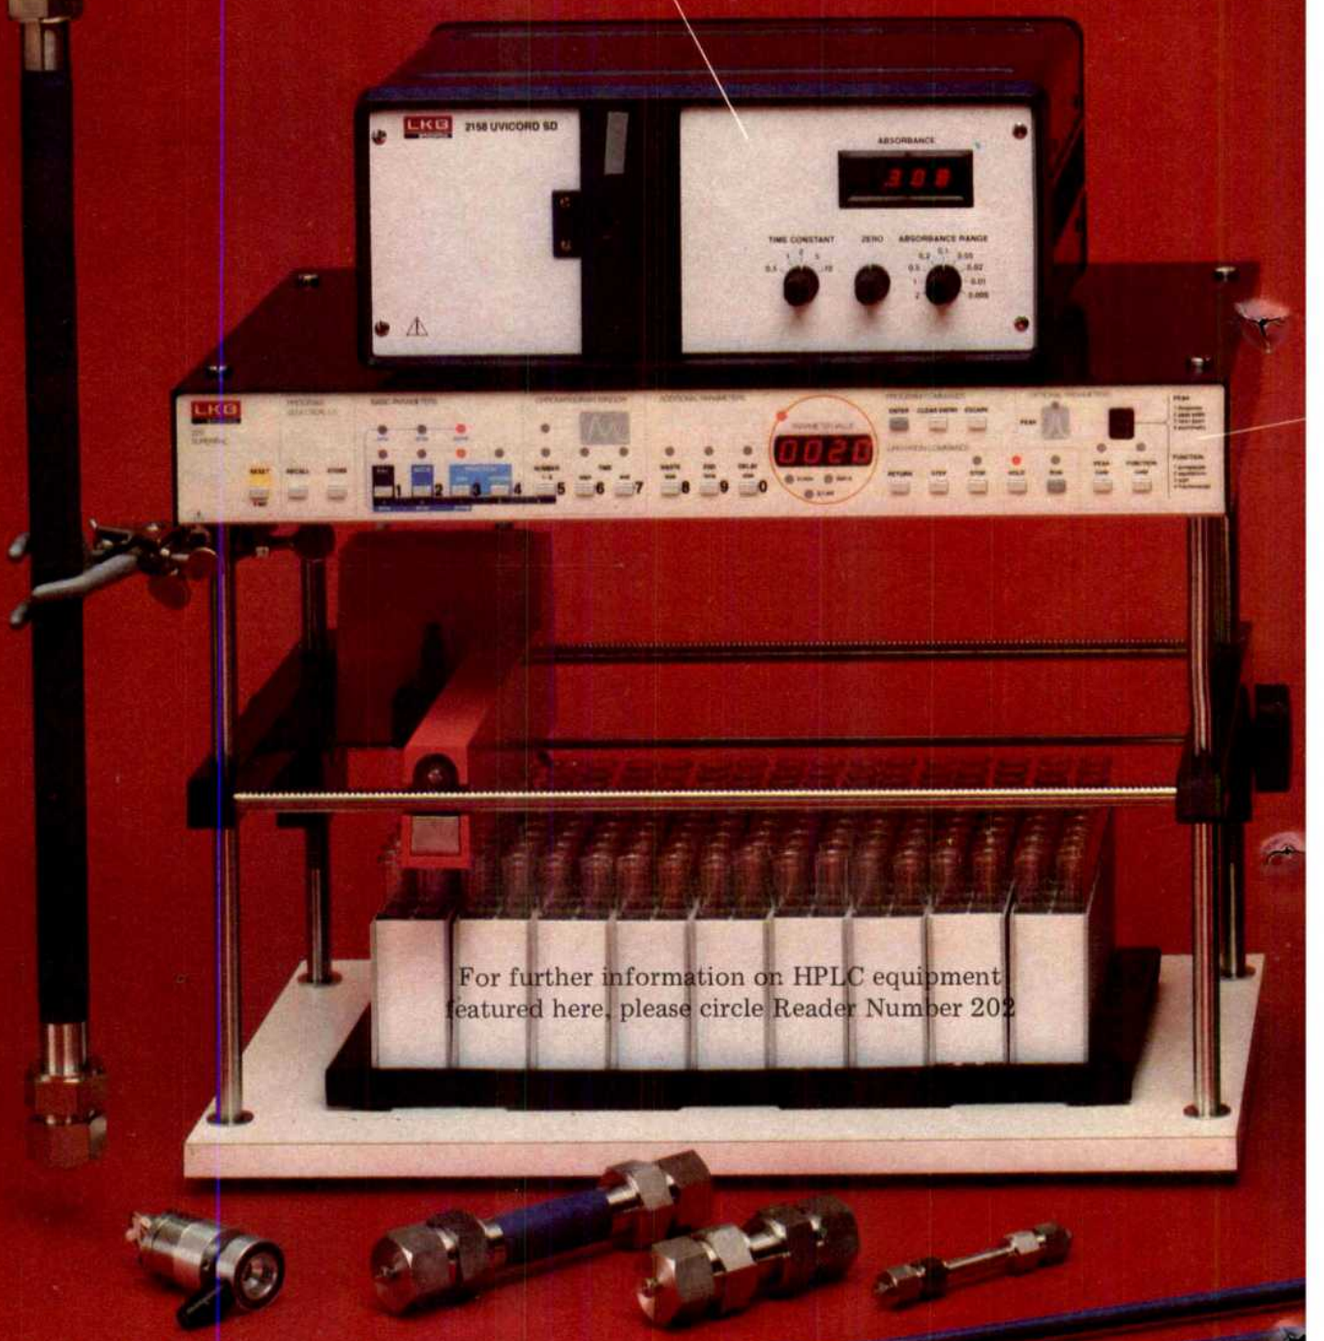
LKB ion exchange systems, for instance, permit the use of volatile buffer solutions (ammonium bicarbonate or ammonium acetate) for highly efficient peptide separations. For large peptides, the LKB HPLC ion exchange system gives better resolution than traditional reversed phase chromatography.



Reversed-phase Chromatography

Sample:	*o*-phthalaldehyde derivatives of amino acids, 1 nMol each
Detection:	330 nm, 0.04 AUFS
Gradient:	10—50 % CH_3CN in 12.5 mM Na-phosphate buffer, pH 7.2
Column:	C18 (5 μm), LKB 2134-215, 4×250 mm

LKB's high performance reversed-phase chromatography systems provide an accurate, reproducible, rapid and inexpensive method for analyzing smaller biomolecules such as peptides, amino acids, PTH-amino acids and nucleic acid components.



Column dimensions and particle sizes have been selected to give maximum separation efficiency, lower detection limits and a minimum of solvent consumption. An LKB high performance *microbore* system (1 mm ID columns), for example, can achieve up to 14 times lower detection limits and solvent savings of up to 95% compared with conventional HPLC systems.

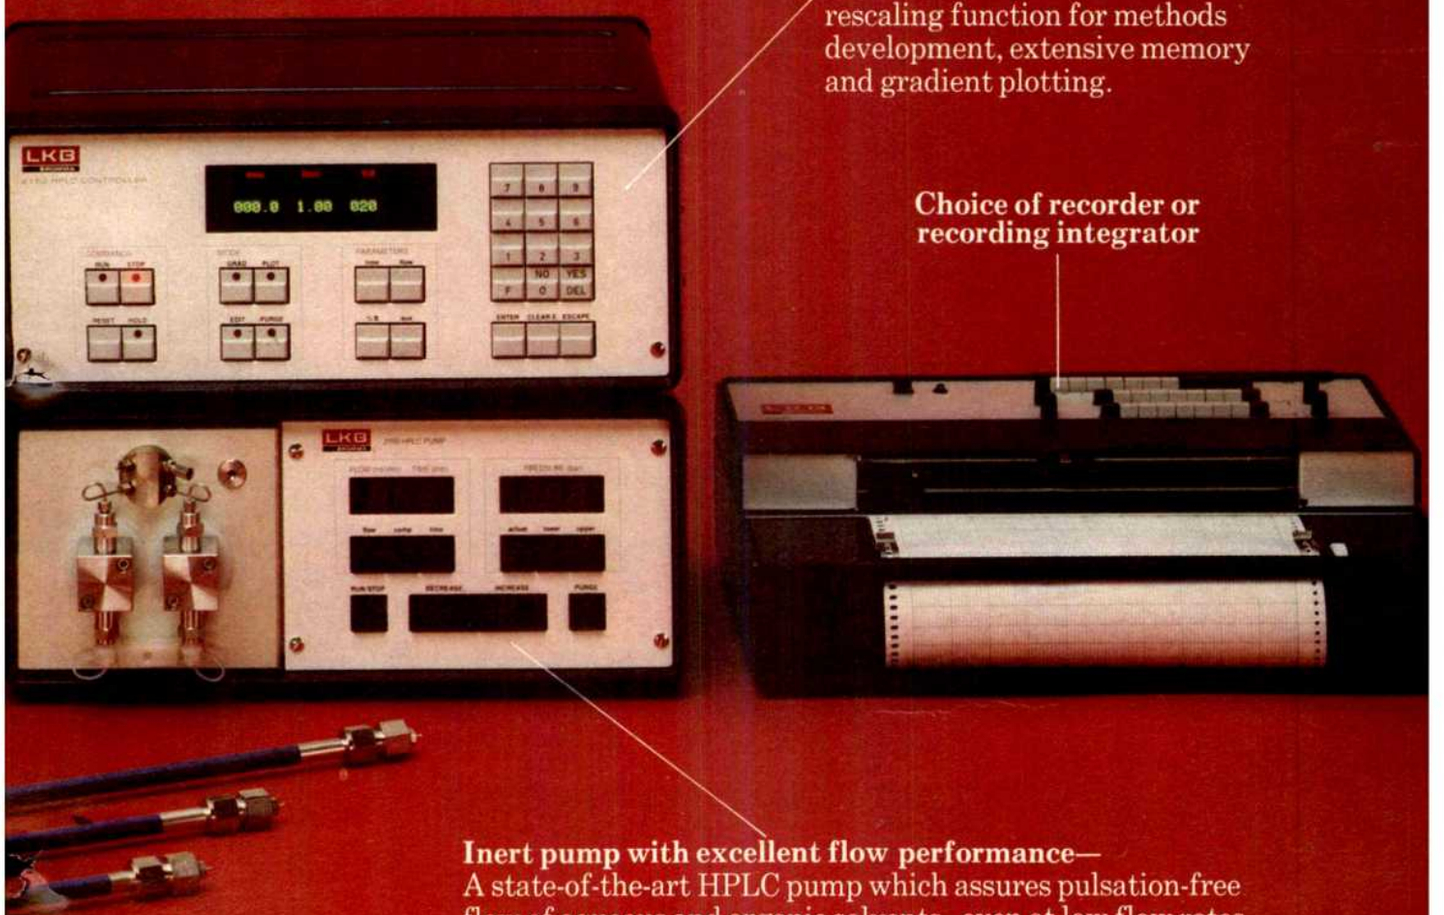
Sample:	PTH amino acids, 1—5 pMol each
Detection:	254 nm, 0.005 AUFS
Eluent:	CH_3CN/THF in NaAc buffer, pH 5.8
Flow rate:	50 μl/min
Column:	C18 (5 μm), LKB 2134-600, 1×250 mm

Optimize your
LKB's modular

Choice of detectors—The versatile Variable Wavelength Monitor or the highly sensitive Uvicord SD with a choice of 3 flow-optimized cells and 7 interference filters.

For further information on HPLC equipment featured here, please circle Reader Number 202

Extensive range of columns and accessories
Prepacked gel permeation, ion exchange and reversed-phase columns with a choice of particle size and column dimensions (for preparative or analytical applications), injector, capillaries & fittings.

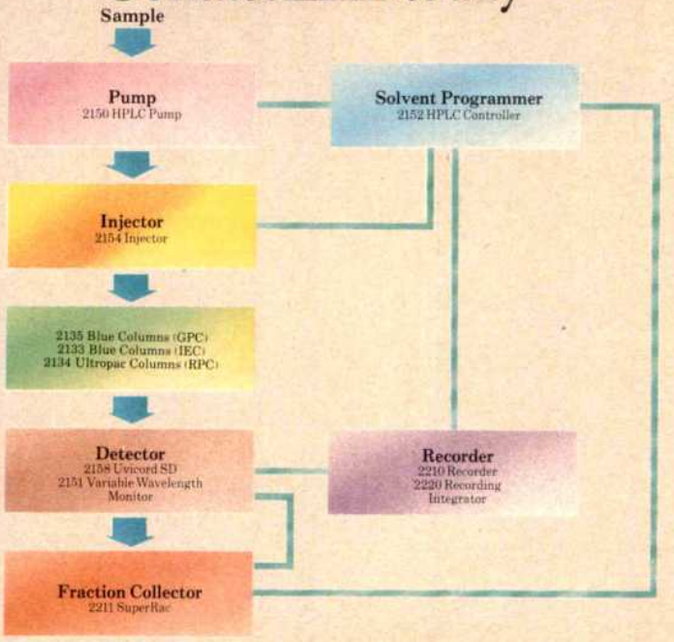


NEW—an expanded range of ion exchange columns.
Ask your LKB representative for more information.

esults with HPLC systems

LKB offers the first modular HPLC system designed to meet both today's general requirements in HPLC as well as the special requirements posed by biomolecular research. Given the relatively low diffusion rates of many large biomolecules, the LKB 2150 HPLC Pump is the only HPLC solvent delivery unit capable of flow-optimized gel permeation and ion exchange chromatography. This unique pump teams up with the 2152 HPLC Controller to provide unprecedented precision, accuracy and complete control of gradient formation—even at the extremes of gradients where very low flow rates are required. Both units are microprocessor-controlled for added precision and reproducibility as well as for ease of use—incorporating convenient pushbuttons and bright and easy-to-read digital displays.

The intelligent fraction collector
SuperRac is the most advanced fraction collector available today, with peak-slope detection, window programming, re-cycling capabilities and an extensive memory.



Accurate gradient elution & complete system control—Simple and accurate system control with rescaling function for methods development, extensive memory and gradient plotting.

Choice of recorder or recording integrator

Inert pump with excellent flow performance—
A state-of-the-art HPLC pump which assures pulsation-free flow of aqueous and organic solvents—even at low flow rates (for high resolution separations of large biomolecules and microbore HPLC).

Contact LKB today

The LKB HPLC System configuration

LKB can provide you with all the detailed and up-to-date information you need on HPLC instrumentation, techniques and applications for the separation of biomolecules. Apart from **Descriptive Catalogues** and **Product Brochures** for all HPLC instruments and chemicals, LKB also publishes **Application and Technical Notes** to help you realize the full potential of your HPLC instrumentation. LKB **Workshops and Seminars** give you support on the theory and practice of HPLC for the separation of biomolecules, and provide you with an opportunity to discuss techniques with other scientists and LKB specialists. A 64-page Seminar Note booklet entitled **HPLC for the Biochemist** and an accompanying **Slide Set** are also available from your local LKB representative.

Earthquake seasonality before the 1906 San Francisco earthquake

Patrick H. McClellan

US Department of Interior, Minerals Management Service, 345 Middlefield Road, Menlo Park, California 94025, USA

Since 1855, 40 earthquakes of magnitude ≥5.5 have occurred on the San Andreas Fault (SAF) system in coastal central California, between latitudes 36°30′ N and 39°30′ N (Table 1)[1]. Of the included 27 'independent' earthquakes, which occurred more than 1 yr after or 1 geocentric degree distant from a previous ≥5.5 mag earthquake, 3 occurred in summer, 7 in autumn, 4 in winter and 13 in spring. All of the spring earthquakes occurred during the 25-yr interval that culminated with the great San Francisco earthquake (8.25 mag) in the spring of 1906 (Fig. 1*a*, *b*). I report here that the observed frequency of the spring earthquakes before 1906 significantly exceeds (binomial $P = 0.002$) seasonal frequencies expected from random variation in the earthquake rate, and thus invites serious inquiry into the subject of earthquake seasonality. More importantly, the time-clustering of spring earthquakes before 1906 raises the question of whether accelerated seasonal seismicity may herald the end of the 'seismic cycle' suspected[1] to modulate the long-term pattern of seismicity on the northern segment of the SAF system.

To avoid the *a priori* assumptions inherent in seasonal grouping of the data, the significance of the apparent earthquake seasonality before 1906 was further assessed with the Schuster test[2], which, as used here, measures the tendency of earthquakes to occur near the same time ('phase') of the year. Each earthquake datum within a year was converted to a phase angle ω_i (1 January = 0°) and the n phases were vectorially added. If

$$A = \sum_{i=1}^{n} \cos \omega_i \quad \text{and} \quad B = \sum_{i=1}^{n} \sin \omega_i$$

then the resultant vector has a net phase $\phi = \arctan(B/A)$ and a length $R = \sqrt{A^2 + B^2}$. The probability of observing a vector longer than R (that is, a better correlation) from a set of n random phases is $P = \exp(-R^2/n)$, where $n \geq 10$ (refs 3–5). The results are listed in Table 2. For the complete set of $n = 27$ independent earthquakes since 1855, $\phi = 119°$ (corresponding to a date of 30 April) with a random probability $P = 0.21$ (not significant). However, for the 19 earthquakes between 1855 and the end of 1905, $\phi = 104°$ and $P = 0.029$. In other words, leading into the year 1906, there was a significant tendency for moderate and large earthquakes to occur not only in the spring but around the date of 15 April. The great San Francisco earthquake occurred on 18 April 1906.

Considering only the 'strongest' independent earthquakes (≥6.0 mag, as defined, for example, in ref. 6) between 1855 and 1906 ($n = 7$) leaves too few events ($n < 10$) to be tested reliably for correlation by the Schuster method[5]. If the magnitude threshold is lowered below 6.0 mag, to enlarge the set of strongest events between those years, seasonality becomes increasingly apparent. Although clustering is not evident for the 10 earthquakes of ≥5.9 mag ($P = 0.35$), it is significant at the $P = 0.07$ level for the 13 events of ≥5.7 mag, and, as noted above, at the $P = 0.029$ level for the 19 events of ≥5.5 mag. This indicates that the weaker earthquakes were, in large part, responsible for the observed seasonality. Alternatively, the set of seven strongest (≥6.0 mag) earthquakes before 1906 may be enlarged by adding to it the three strongest known pre-1855 central California earthquakes (Table 3), which reasonably are assumed also to have exceeded 6.0 mag[7]. Those 10 strongest earthquakes collectively are correlated, albeit marginally ($P = 0.07$–0.09; Table 2), about the dates of 23–28 May, with most occurring in the spring season within the quarter-century before 1906.

Table 1 Earthquakes (≥5.5 mag) in coastal central California from 36°30′ N to 39°30′ N, 1855–1982

Year	Date	Time	Latitude	Longitude	Magnitude

1980	1 24	19:00	37°50′ N	121°48′ W	5.8
1980	1 27	2:33	37°51′ N	121°47′ W	5.5

Data are from the catalogue in ref. 1, Appendix, Table A1. All magnitudes before 1900 and some during 1900–27, are intensity magnitudes (M_I) estimated from published felt-area data on the basis of empirical relations between local magnitude (M_L) and extent of isoseismal areas for twentieth-century earthquakes in California and western Nevada[14]. A test of M_I against M_L for twientieth-century earthquakes in coastal central California[1] suggests that, for this subregion, M_I is slightly conservative and may underestimate M_L by about 0.2 ± 0.2 units. Thus, the intensity magnitudes listed are presumed to be not greatly biased relative to the instrumental magnitudes. Magnitude listed for the 1906 event is surface-wave magnitude (M_S), M_L recently determined at 6.9 (ref. 15).

* 'Independent' events, which were separated by more than 1 yr or 1 geocentric degree.

Possible explanations for the observed earthquake seasonality include (1) incompleteness of the ≥5.5 mag earthquake catalogue, (2) fortuitous sampling of the catalogue by the assumed criteria of event independence, (3) fortuitous sampling of a limited geographical segment of the SAF system, (4) a real, though improbable, random variation in the earthquake occurrence rate and (5) a fundamental geological process. Because the catalogue is believed[1] to be complete for events down to 5.5 mag, it is unlikely that the observed high spring seismicity is due to the omission of numerous large earthquakes in other seasons. Likewise, the pattern probably is not an artefact of fortuitous sampling of the ≥5.5 mag catalogue, inasmuch as assuming the least conservative definition of event independence (Fig. 1*c*) also results in a disproportionately high frequency of

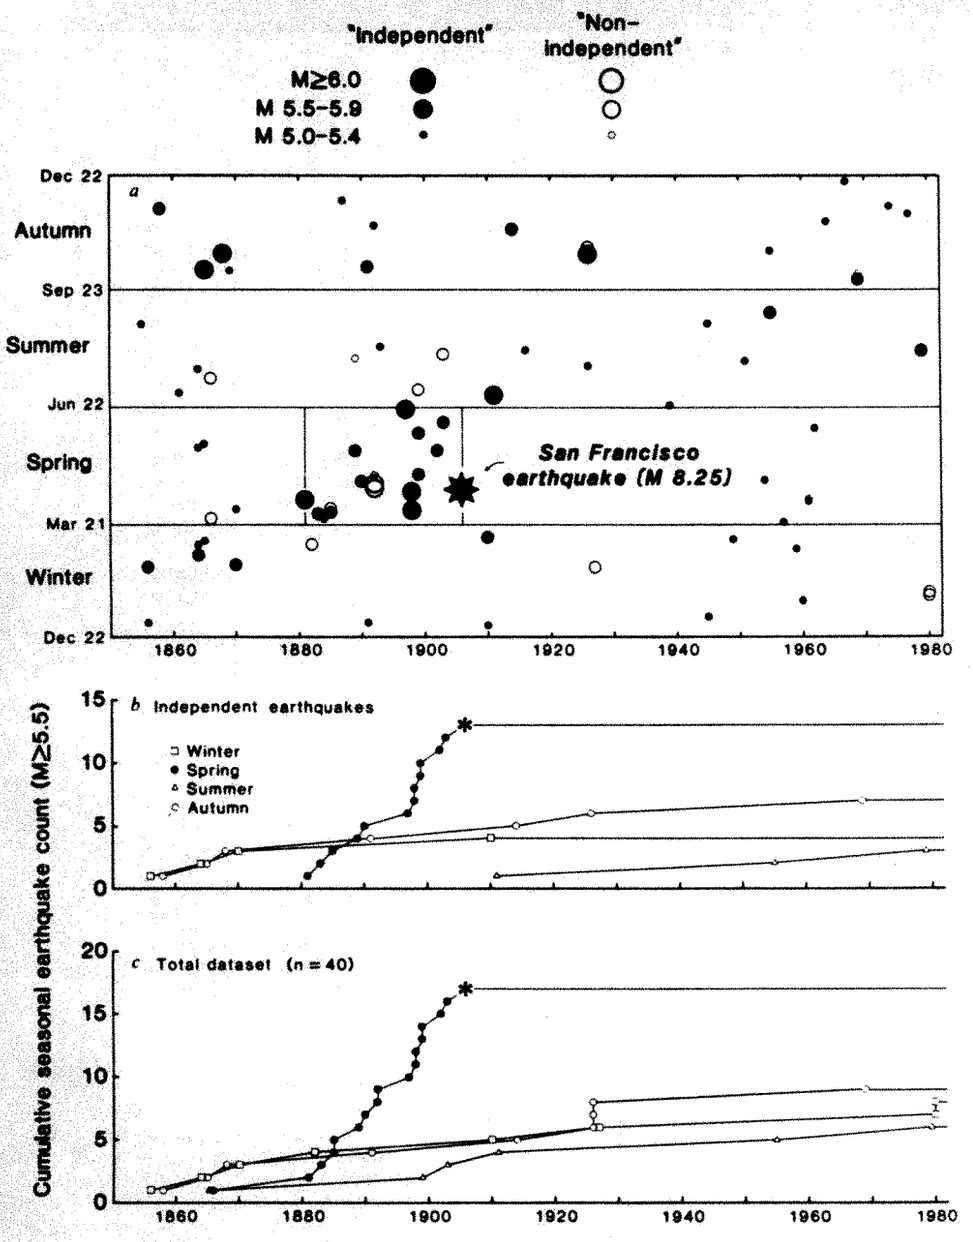

Fig. 1 *a*, Year-season plot of moderate to large (≥5.5 mag) earthquakes in coastal central California (36°30′–39°30′ N) from 1855 to 1983. Independent ≥5.5 mag events are defined as those separated by more than 1 yr or 1 geocentric degree. Seasons are defined by the conventional dates of the winter solstice (22 December), vernal equinox (21 March), summer solstice (22 June) and autumnal equinox (23 September). *b*, Cumulative count by season of independent ≥5.5 mag earthquakes plotted in *a* ($n = 27$). *c*, Cumulative count by season of total ≥5.5 mag earthquake set plotted in *a* ($n = 40$).

spring earthquakes. A more conservative assumption than was used seems unreasonable.

Regarding the geographical limitation of the earthquake sample, Schuster analysis of independent strong earthquakes (≥6.0 mag) on the southern SAF system (33–36° N, $n = 13$)[6], beginning with the great 1857 earthquake there to the present time, show that those events also are correlated ($P = 0.04$) about a date in the spring (31 March), as are those earthquakes in combination with the 10 strong earthquakes since 1855 in central California (36°30′–39°30′ N; Table 1) plus 12 other post-1855 events of about ≥6.0 mag which occurred on the SAF system between 33–36.5° N (Table 3)[7], but were not included in the list in ref. 6. This total set of ≥6.0 mag earthquakes ($n = 35$) is correlated ($P = 0.04$) about the date of 20 April, and suggests that the observed earthquake seasonality in coastal central California is stable against geographical extensions of the earthquake sample, at least for the strongest historical events over the extent of the SAF system. (Smaller earthquakes throughout the system were not analysed.) Finally, although the 25-yr-long sequence of spring earthquakes in central California may have been a mere coincidence of random events, the termination of the sequence with the unique 1906 earthquake circumstantially suggests otherwise. Thus, coastal central California appears to have been tectonically predisposed to the frequent occurrence of moderate to large earthquakes during the spring season from 1881 to 1906.

A physical basis for the observed earthquake seasonality on the northern segment of the SAF system can only be conjectured at present. Nevertheless, the fundamental mechanism almost certainly involves the manner in which elastic strain accumulates in the crust along that portion of the North American–Pacific plate boundary. Crustal strain accumulating there is released primarily in ground-rupturing earthquakes on the SAF that are probably similar in size to the 1906 earthquake and are believed to occur there at intervals averaging from 150 yr[1] to perhaps 230 yr[8] in length. This range of estimated recurrence intervals approximates the average of 145 yr (range 100–225 yr) between large or great ground-rupturing earthquakes on the south-central SAF, like the 1857 event, during the past 17 centuries (K. E. Sieh, personal communication). In addition, in coastal central California, overall historical seismicity above the 5.0 mag level was generally higher during the half-century before the 1906 earthquake than in the half-century afterward[1], not unlike a pattern, called the 'seismic cycle'[9,10], observed before and after great earthquakes in the Wadati–Benioff zones of the western Pacific basin. However, an unequivocal precursory increase in seismicity, as characterizes 'Stage II' of this cycle[10], has not hitherto been identified in pre-1906 earthquake data

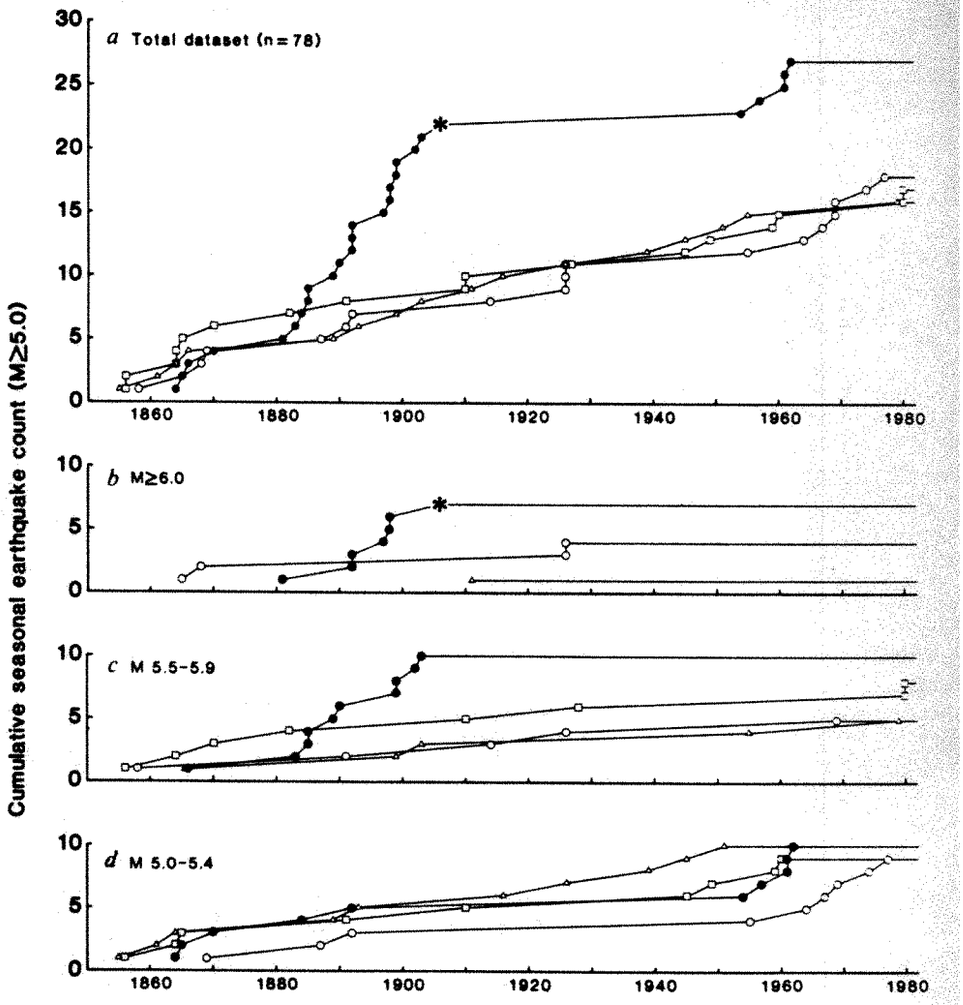

Fig. 2 *a*, Cumulative count by season of ≥5.0 mag earthquakes in coastal central California from 1855 to 1983, listed in ref. 1 ($n = 78$). *b*, Total ≥6.0 mag earthquake subset in *a*. *c*, Total 5.5–5.9 mag earthquake subset in *a*. *d*, Total 5.0–5.4 mag earthquake subset in *a*.

from central California[1,11]. Nevertheless, the quasiperiodic recurrence of great earthquakes on the northern SAF is suspected[1] to control a seismic cycle there also.

Conjectural mechanisms which might have selectively triggered earthquakes in the spring on faults in the SAF system necessarily presuppose that, before triggering, those faults were already tectonically strained to near the point of shear failure. It is not unreasonable, in retrospect, to assume that such a pre-strained condition became increasingly prevalent in the 25 yr leading up to 1906. Possible seasonal triggering mechanisms may be classified on the basis of how they might affect the three terms in the stress ratio:

$$\frac{\tau}{s_n - p} = K$$

where τ is shear stress, s_n is normal stress, p is pore-fluid pressure along a pre-existing fault, with K the critical ratio above which shear failure will occur in the given medium[12]. In theory, on a near-critical fault, any seasonal process which might relatively increase shear stress and/or pore pressure, or relatively decrease normal stress, could potentially destabilize the fault and trigger rupture, and thus account for earthquake seasonality before a great earthquake. Although limited space prevents a detailed discussion of candidate seasonal processes, Table 4 outlines several that might be most effective in the spring. Those listed are ordinarily nominal ambient processes which clearly would not be expected to trigger slip on faults at low strain levels. On faults at high strain levels, however, such as the subparallel faults in the San Andreas system late in a seismic cycle, the listed triggering mechanisms conceivably could introduce a seasonal bias into the time-distribution of earthquakes. In the absence of high pre-stress, such as early in a seismic cycle, or of a seasonal triggering influence, earthquakes would be expected to distribute themselves randomly throughout the year, as they have been distributed in coastal central California since 1906 (≥5.0 mag: Schuster $P = 0.70$).

Table 2 Schuster test results for selected subsets of earthquakes in coastal central California

	1855–1982	1855–1905	1907–1982	1808–1905*	1808–1982*

P	0.41	0.08	0.70		

n, Number of earthquakes ('annual phases') in subset.
ϕ, Time of year (corresponding to net phase angle) near which earthquakes in subset tended to occur.
R, Vector sum over subset of earthquake phase angles.
P, Probability of observing a vector sum greater than R if n phases were random (valid for $n \geq 10$)[5].
* Subset includes three largest pre-1855 central California earthquakes: in 1808, 1836 and 1838 (Table 3). For the undated June 1838 event, extreme dates of 1 June and 30 June were assumed in calculating possible ranges for ϕ and P.

The above observations provide evidence for precursory seasonal seismicity leading up to the great San Francisco earthquake. Although the observations may be statistically significant, whether they are also physically significant remains to

Table 3 Other strong (≥6.0 mag) earthquakes in coastal central and southern California (see text)

Date	Latitude	Longitude	Maximum modified Mercalli intensity	Magnitude
1808 6 21	37°48′ N	122°30′ W	VIII	?

Pre-1900 earthquake data from ref. 7; post-1900 data from ref. 16; 1983 data (Coalinga earthquake) from University of California Seismographic Station, Berkeley. Pre-1900 magnitudes are M_I; post-1900 magnitudes are M_L, except for 1927 event, which is M_S.

Table 4 Conjectural mechanisms for springtime seismicity

1. *Pore-fluid pressure increase*
   - *a*, Downward-propagating pulse of above average crustal pore pressure due to increased infiltration of water from surface and subsurface reservoirs refilled by winter rainfall.
   - *b*, Static unloading of crust in coastal region by seasonal decline in monthly mean sea level of the order of 20 cm, leaving overpressures on pre-stressed faults at depth; minimum occurs in springtime off central California and follows a decline which may exceed 30 cm over a 2-month period (if after a winter-long high sea level anomaly, or 'El Nino')[17–19].
2. *Increase in shear stress and/or decrease in normal stress*
   - *a*, Springtime increase in northwestward force vector on northwestward-moving Pacific plate due to increasing inclination of Northern Hemisphere toward Sun. (As this notion might predict, strong earthquakes on the 1,100-km long SAF system tend to occur near a date earlier in the spring in the south (31 March) than in the north (late May).)
   - *b*, Interaction at the plate boundary of torques on the Pacific and North American plates resulting from the springtime deceleration of Earth's rotational spin (manifested by springtime increase in the length of day)[20].

be demonstrated. Nevertheless, the evidence corroborates, if rather oddly, the suspicion that a seismic cycle governs the long-term behaviour of the northern SAF system. If the historical pattern of earthquake seasonality is characteristic of that long-term behaviour, several interesting inferences are possible.

(1) Based on the absence since 1906 of frequent spring earthquakes of ≥5.5 mag in coastal central California, (or, perhaps, of high seismicity in another season), a repeat of the 1906 earthquake on the San Andreas fault is probably at least a quarter-century away (as others have concluded[1]). (2) Should a seasonal seismicity pattern re-emerge, the contemporary practice of estimating cumulative and annual probabilities of expected major earthquakes (see, for example, refs 11, 13) may be refined to the precision of seasonal probabilities. (3) Seasonal analysis of historical seismicity on shallow faults elsewhere in the world may yield similarly predictive results. (4) Seasonal analysis of other kinds of solid-Earth geophysical data, such as ground tilt, strain, creep, gravity, tectonomagnetism, microseismicity, well-water level and frequent data from land-based and astrometric geodesy obtained by radio and laser interferometric surveys, may likewise identify informative reltionships to earthquake activity. In this manner, some seasonal variations in instrumental data hitherto attributed to meteorological 'noise' may prove to have a deeper significance.

Localized uplift in the Scottish Dalradian

T. J. Dempster

Grant Institute of Geology, University of Edinburgh, West Mains Road, Edinburgh EH9 3JW, UK

Rb–Sr mica ages are reported here, from the Dalradian metasediments of the Angus region in the Scottish Highlands (Fig. 1), in a study of the uplift history of this classic metamorphic terrain. The samples come from across the Barrovian metamorphic zones[1], and provide evidence of diachroneity in both metamorphism and later cooling. Thus, the oldest mineral ages, and hence earliest cooling, are found in the highest grade metamorphic rocks to the north. The results show the importance of tectonically-controlled, localized uplift processes. Given that erosion is an important influence on the thermal development of metamorphic rocks[2], the constant or steadily decaying isostatic uplift rates, often assumed in models of orogenic belts[2,3], may be a marked oversimplification of the real events.

The major structure of the Dalradian is dominated by pre-metamorphic nappe structures[4], represented by the Tay and Tarfside Nappes in the present area[5] (Fig. 1). The rocks considered in this study come from the roughly flat-lying, right way-up limb of the Tarfside Nappe, along the line A–B in Fig. 1. Essentially, the area is considered to show a continuation of the flat belt and Highland Border Steep Belt of Perthshire, with the axial trace of the post-metamorphic Highland Border Downbend dividing these two domains. The flat belt region, in the area of the A–B traverse, also shows the complication of the late Tarfside Culmination[6] in the north of the area (Fig. 1). Regional metamorphic grade increases away from the Highland Boundary Fault, from the chlorite zone[7] to the sillimanite zone in the north[1]. Estimates of the age of peak metamorphism in the Dalradian, range from 515 to 490 Myr (refs 8, 9), although

0028–0836/84/020156—04$01.00

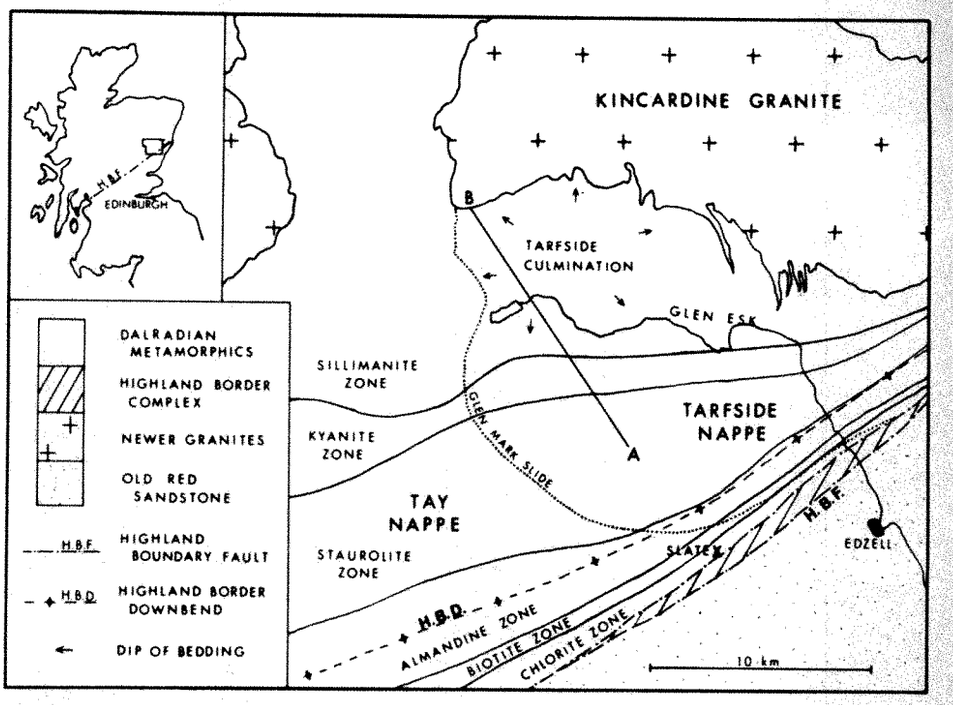

Fig. 1 Structural and metamorphic map of the Angus region in the Scottish Highlands (partly based on Barrow[1] and Harte[5]), showing the location of traverse A–B.

the Lower Palaeozoic metamorphism over the Scottish Highlands as a whole may show considerable diachronism[10,11]. Metamorphism in this traverse is roughly contemporaneous with other areas in the Dalradian, with the metamorphic climax approximately synchronous with the third regional deformation event (D3). However, slightly earlier garnet and staurolite porphyroblast growth, relative to the D3 mica fabric, is seen in the lower grade rocks, in the south of the traverse.

The interpretation of isotopic mineral ages in slowly cooling metamorphosed rocks is largely based on the theory of closure temperatures[12,13]. This predicts that minerals will record the times at which they cool through characteristic temperatures, below which the mineral is closed to the relevant isotopic exchange. Thus, biotites, with approximate Rb–Sr closure temperatures of 300 °C (ref. 12), record younger ages than coexisting muscovites, with higher Rb–Sr closure temperatures of about 500 °C (ref. 12). Dewey and Pankhurst[14] examined K–Ar mica ages from the Scottish Highlands and showed a broad relationship between the mineral ages and metamorphic grade, with younger ages and delayed cooling in the hotter, more deeply buried rocks. Thus, it might be expected that with roughly simultaneous metamorphism and uniform uplift, earlier cooling to mica closure temperatures, and hence older ages, would be seen in the lower grades to the south, along the present profile.

In this detailed study along the traverse A–B (Fig. 1), biotite and muscovite were separated from biotite–muscovite–plagioclase-bearing schists and analysed, together with whole-rock samples by Rb–Sr isotope dilution methods described elsewhere[15]. Details of all mineral age results, presented in Fig. 2, are available on request, and a selection of isotopic data is given in Table 1. The grain sizes and chemical compositions of each mica are relatively constant in the samples of this study and hence probably have little control on closure temperatures[17] or age variation. Thus, the isotopic age pattern (Fig. 2) largely reflects variation in the time of cooling to approximately uniform closure temperatures. It should be emphasized that the relative mica ages observed are more critical to any interpretation than the absolute ages and values of closure temperatures adopted.

The Rb–Sr mineral ages are corrected for initial Sr using the whole-rock analysis, and if the mica ages in the narrow thermal aureole of the Kincardine Granite are examined, this approach seems to be justified. Thus, mica ages are reset to an age of intrusion (~410 Myr), consistent with other independent estimates of the timing of Newer Granite emplacement[18]. So, the micas must exchange with a low $^{87}Sr/^{86}Sr$ phase, and any uncertainty in the exact composition of this phase, is more than outweighed by the large spread in Rb–Sr ratios of the exchanging phases.

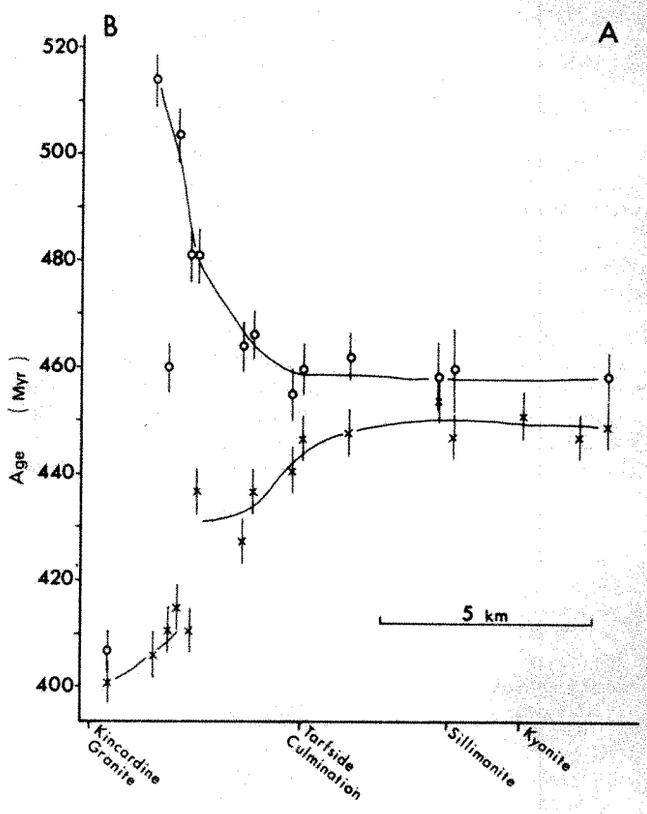

Fig. 2 Mineral age results from traverse A–B shown in Fig. 1. ○, Rb/Sr muscovite; ×, Rb/Sr biotite.

The whole-rock K–Ar dating of a well-crystallized slate, containing muscovite as its only major K-bearing phase and only one generation of white-mica, gives an estimate of the timing of metamorphism[9] in the chlorite zone (Fig. 1) of 489 ± 10 Myr (Table 1). Surprisingly, the oldest Rb–Sr muscovite age of 514 ± 5 Myr is found in the north of the traverse, which gives a minimum estimate of the timing of metamorphism in the high grades and supports textural evidence of diachroneity of

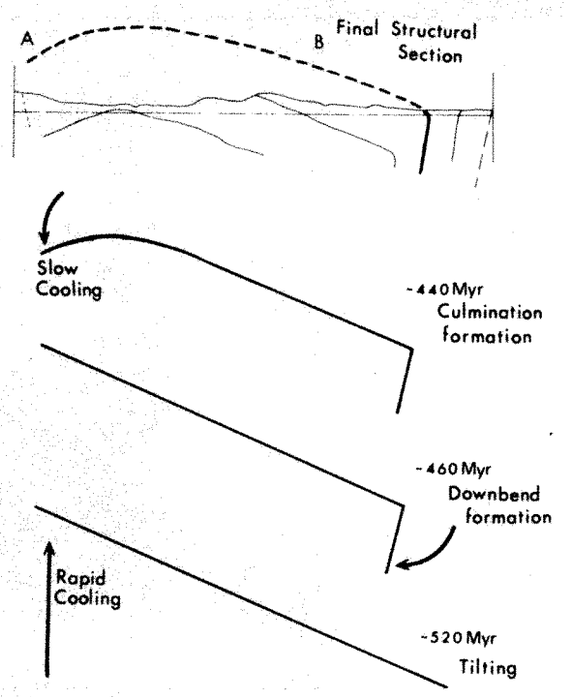

Fig. 3 Schematic sections showing the proposed structural evolution and cooling history that results in the mineral ages shown in Fig. 2.

metamorphism in the region. The old muscovite cooling ages in the north of the transect (Fig. 2) must indicate extremely rapid cooling, from the estimated peak metamorphic temperatures of ~650 °C (ref. 18), to below the approximate Rb–Sr closure temperatures of muscovite of ~500 °C (ref. 12) (although this rapid cooling itself may slightly increase the closure temperatures[16]). No evidence of this early rapid cooling is seen immediately to the south, where, despite a roughly similar (D3) textural age of metamorphism, initial slow cooling is indicated by Rb–Sr muscovite ages of ~460 Myr. However, a gradual transition occurs from the north towards the centre and to the south of the Tarfside Culmination occurs, as shown by the steady southerly decrease in the muscovite ages. After the initial rapid cooling in the northern area, very slow cooling must have followed as shown by the relatively young biotite Rb–Sr ages of ~430 Myr. Again contrasting behaviour is seen to the south of the Tarfside Culmination, in that the similarity of muscovite (~460 Myr) and biotite (~450 Myr) ages implies relatively rapid cooling and uplift for this area at a late stage.

Neither of the prominent post-metamorphic structures, the Highland Border Downbend or the Tarfside Culmination, seem to be capable of causing the early uplift, which is necessary for the rapid cooling in the very north. The Downbend structure must postdate the cooling and uplift in the sillimanite zone, as it deforms the Arenig fossil-bearing[19] (~480 Myr)[20] Highland Border Complex[21], and also folds the metamorphic zones of the lower grade areas[18], which are developed after cooling in the north. Similarly, the Tarfside Culmination is a young dome-structure and the old ages come from the northwestern rather than the central parts of the dome (Fig. 2). A striking feature of the Angus region is the significant dip of the 'flat belt' (to the south of the Tarfside Culmination) at angles of ~30° to the south-east, compared with the virtually horizontal beds of Perthshire[4]. It is suggested, as shown in Fig. 3, that an early tilting of originally flat-lying beds could result in rapid uplift, erosion and cooling in the most northerly rocks, which before the Culmination formation would be the highest level rocks (Fig. 3). This suggests that the Culmination forms subsequently by relative downwarping of the beds to the north, as a consequence of which, the once coolest rocks to the north, become the slowest cooling and show the youngest biotite ages (Fig. 2).

Thus, tectonic activity may be largely responsible for the cooling and uplift pattern in this part of the Highlands. A syn- to post-metamorphic tilting would also explain the diachronous metamorphism in this area, with convection of heat by rapid uplift[2], hastening the approach to peak metamorphic conditions. Thus, earlier-metamorphosed, higher-temperature rocks will be exposed in more rapidly uplifted areas. The approximately horizontal dip of the flat belt elsewhere in the Southern Dalradian, suggests that not only is the rapid early uplift localized in the north of the area considered, but is probably not seen elsewhere along the belt. This may account for the exposure of low level Tarfside Nappe rocks at the expense of the inverted Tay Nappe rocks to the south-west[5] (Fig. 1).

Clearly, such major cooling and uplift rate variations cannot be accommodated into regional (on the scale of the Grampian Highlands) block uplift events with steady isostatic return to normal crustal thicknesses[2,22]. It is apparent that localized uplift relating to structural activity and possibly decoupling and movement of small blocks in the basement is an important late tectonic

feature of the Dalradian evolution. Given that there seems little reason to believe that the Lower Palaeozoic metamorphic belt of the Scottish Highlands should be markedly different from other orogenic belts, thermal models of metamorphic evolution in thickened crust, involving steadily decaying uplift processes[3,22], are probably an oversimplification.

These results must also cast doubt on the technique of assessing closure temperature variation, by comparing mineral ages over large tracts of metamorphic rocks on the assumption of uniform uplift and metamorphism[23]. The occurrence of localized uplift phenomena, within a regional metamorphic terrain, will also influence the variation in metamorphic grade or facies series or piezothermic arrays[24] (metamorphic geotherms[2]) across the terrain. Thus, a change in facies series[18] may partly reflect localized lateral (rather than vertical) differences in P–T-time paths for individual rock units. One further consequence of localized uplift is that it may also cause lateral redistribution of heat, thus, small uplifting areas may act like syn-metamorphic intrusions with respect to surrounding non-uplifting areas.

The support of a NERC grant is acknowledged and I thank Ben Harte for his encouragement and supervision, and John Hutchinson for assistance with mass spectrometry performed at the Scottish Universities Research and Reactor Centre.

Period multupling-evidence for nonlinear behaviour of the canine heart

Amy L. Ritzenberg*, Dan R. Adam† & Richard Jonathan Cohen*†

* MIT Department of Physics and † Harvard-MIT Division of Health Sciences and Technology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Although there has recently been considerable interest in applying the theory of nonlinear dynamics to the analysis of complex systems[1,2], as yet applications of the theory to biological systems *in vivo* have been very limited. We report here evidence of nonlinear behaviour in the electrocardiogram and arterial blood pressure traces of the noradrenaline-treated dog. Noradrenaline produces variations in these traces that repeat themselves with regular periods of integral numbers of heart-beats (period multupling), an effect that resembles the 'period-doubling' and other 'bifurcative' behaviour[3–5] observed when the driving frequency of a nonlinear oscillator is increased above a critical value[6–9]. The simplest type of periodic variation that we report is the so-called 'electrical alternans', which has long been known as one response of cardiac electrical activity to certain stresses and disease states[10–13].

Ten dogs were anaesthetized with sodium pentobarbitol and ventilated with a respirator at a fixed rate (to distinguish electrocardiogram (ECG) modulation due to respiration). Saline-filled catheters were introduced into the femoral artery and vein, and arterial blood pressure (ABP) tracings obtained. Unipolar leads were placed precordially and the surface ECG recorded. Noradrenaline bitartrate was given intravenously in a dosage sufficient to intoxicate (indicators being substantial sinus tachycardia and arterial hypertension). Dosages ranged from 0.02 to 0.05 mg kg^{-1}. To confirm the presence of period multupling more rigorously than via a simple visual inspection of the traces, ECG and ABP records were digitized and then fast Fourier transformed and the spectra plotted. According to Fourier theory, the Fourier spectrum of a record with no period multupling should contain sharp peaks only at the heart rate and at integral multiples (the Fourier harmonics) of that frequency. Period doubling (alternans) should appear in the spectrum as an isolated peak (subharmonic) at a frequency equal to one-half the heart rate and additional peaks at integral multiples of this frequency; period tripling should appear as peaks at integral multiples of the frequency equal to one-third the heart rate, and so on (hence 'period multupling' corresponds to frequency dividing).

The results of this means of analysis are summarized in Table 1. One of the 10 dogs fibrillated spontaneously upon injection with noradrenaline and is thus excluded from the study. Of the nine remaining, seven displayed modulations of clearly discernible order. There were several instances of period doubling, tripling, quadrupling and quintupling. Figure 1 shows typical episodes of tripling and quadrupling; ECG, ABP and their respective Fourier spectra are displayed. The time scale for these observations is as follows: episodes of 4.25 s or more were considered stable. Intervals of apparent stability ranged from approximately 6 s (an instance of quadrupling) to tens of seconds (instances of doubling). Inter-episode (apparently aperiodic) times varied from tens of seconds to minutes. In this study, multupling was always found in both ECG and ABP, but never in only one. Thus, we would expect that this phenomenon is not only electrical (periodic alterations of the pattern of conduction through the heart) but mechanical as well (affecting the contractile action of the heart as a whole). Since the frequency of the ECG modulation was unrelated to the frequency of respiration, the effect is not respiratory in origin.

If the analogy with a driven, nonlinear oscillator is appropriate, the heart rate should correlate strongly with the period multupling regime[14]. For example, in our experience of oscillators doubling precedes either tripling or quadrupling, quadrupling precedes quintupling, but quadrupling precedes tripling, due to the particular way in which the new regimes are generated (beyond the scope of this letter), as the driving frequency of

Table 1 Period multupling regimes observed

Animal	Regime	Ventricular rate	Animal	Regime	Ventricular rate

Experimental animals are numbered 1–10. For the seven animals in whose ECG and ABP traces regimes of period multupling were observed, the various regimes are displayed.

© 1984 Macmillan Journals Ltd

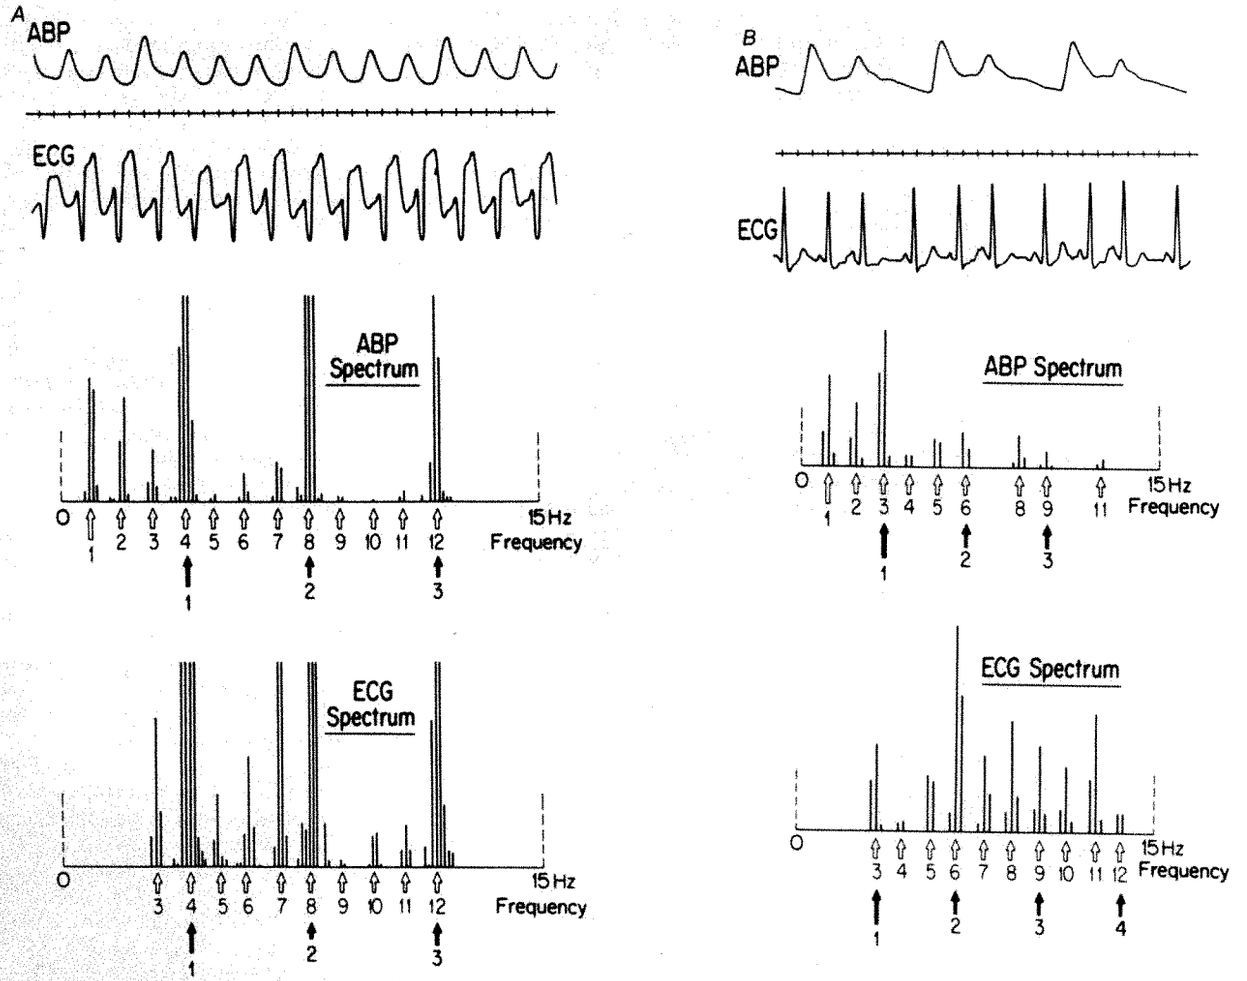

Fig. 1 ABP and ECG traces are displayed, followed by their respective fast Fourier transforms. In *A*, the heart rate is 228 beats per min, making the beat frequency 3.8 Hz (large black arrow). Subharmonics (large white arrow for the first, at 0.95 Hz) appear at quarters of the beat frequency, indicating quadrupling. In *B*, the heart rate is 198 beats per min making the fundamental frequency of atrial beating 3.3 Hz. This appears (large black arrow) as a major peak in both spectra. Subharmonics (large white arrow for the first, at 1.1 Hz) appear at thirds of this frequency, indicating period tripling. In both *A* and *B*, higher Fourier harmonics are shown with smaller arrows; black for higher harmonics of the beat frequency and white for higher harmonics of the multupling frequency. The number below the arrow gives the order of harmonic. (The amplitudes of the first few subharmonics in the ECG spectra are too low to appear on these plots; their higher Fourier harmonics show their presence.)

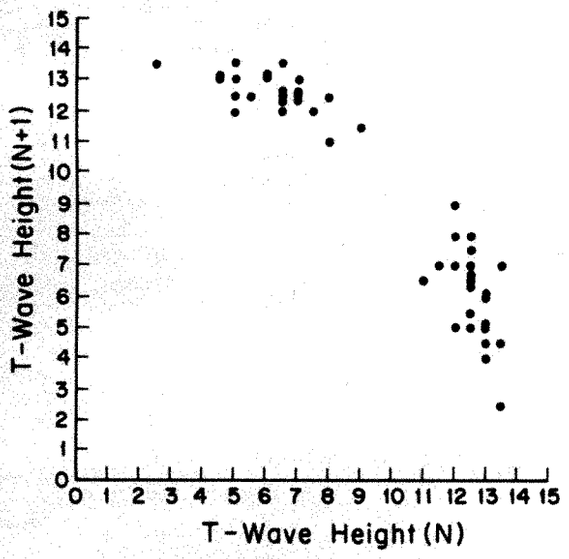

Fig. 2 The height of the $N+1$st T-wave plotted against the height of the Nth T-wave during 48 beats of an episode of period doubling (animal 1).

the nonlinear oscillator is raised. This precedence of period multupling regimes with increasing heart rate was obeyed in all cases (Table 1).

The period multupling behaviour described here may arise in different instances from different electrophysiological mechanisms. For example, in Fig. 1*A*, the intraventricular beat interval is fixed. Period quadrupling in the ECG record is comprised of modulation of the shape of the QRS and T-wave complexes. This suggests that the electrical pattern of depolarization and repolarization varies on a beat-to-beat basis. In Fig. 1*B*, the period tripling shown in ECG and ABP spectra reflects the timing of atrial excitations (which effectively penetrate the atrioventricular junction to activate the ventricles) as well as the sort of excitation pattern variability of Fig. 1*A*. Other mechanisms of period multupling include medically well known bigeminy, trigeminy and quadrigeminy, in which every second, third or fourth ventricular beat originates from a ventricular focus; and a variety of forms of second-degree atrioventricular block. We suggest here that period multupling is a common response of the electrical and mechanical activity of the stressed heart, even when apparently diverse mechanisms are operative.

The observation of period multupling in the canine heart upholds the naive expectation that this system is nonlinear, since a strictly linear system can never exhibit period doubling[3,14]. Recent work on the driving and resetting of neural oscillators,

including excised heart tissue, supports this[15–19]. One simple way to analyse such a system for linearity is to explore the functional dependence of the shape of one beat on the previous beat. We have generated 'scatter diagrams' (Fig. 2) of the T-wave peak height or T-wave area for the $N+1$st beat against the Nth. The degree of 'scatter' (range of ordinates corresponding to one abscissa) is a measure of how closely the $N+1$st beat depends for its shape solely on the shape of the Nth. Our plots show both the strong causal link between the Nth T-wave amplitude and the $N+1$st (that is, a small degree of scatter) and the nonlinearity of that causal relationship.

Further, from Li and Yorke's proof[20] the existence of tripling indicates that the cardiac system is sufficiently nonlinear to produce responses to atrial driving of all periodicities plus pseudostochastic sequences of waveforms. This leads us to ask why we saw no orders of period multupling higher than that of quintupling. A related question is why signals of a relatively low order of multupling alternate chronologically in our records (corresponding to similar heart rates and other system parameters) with aperiodic stretches. One answer is that there are several scenarios for the period multupling of noiseless nonlinear oscillators which predict the existence of intercalated bands of chaotic and periodic activity; in particular, the phenomenon of 'intermittency' is relevant[21,22]. Alternatively, noise disrupts the bifurcation structure of an idealized, non-linear system[8,9]. Higher order orbits are empirically more fragile (due to their smaller parameter space) and subject to effacement, so they are simply less likely to be observed. For example, Duffing's oscillator, when subjected to white noise, is found to develop a symmetrical gap in its bifurcation sequence. Higher-order orbits can even be induced solely by increasing the amplitude of the noise. In the heart, there are many sources of noise, in the form of stochastically varying parameters governing cardiac function; such as intrinsic fluctuations in the atrial rate, and variation in conduction and contractility due to local areas of ischaemia that develop in the stressed heart.

Our results support the model of the noradrenaline intoxicated heart as a highly nonlinear, driven oscillator subject to noise thus usefully linking many seemingly disparate dysrhythmias as bifurcative responses to variation in system parameters.

Brain potentials during reading reflect word expectancy and semantic association

Marta Kutas & Steven A. Hillyard

Department of Neurosciences, M-008, University of California, La Jolla, California 92093, USA

The neuroelectric activity of the human brain that accompanies linguistic processing can be studied through recordings of event-related potentials (e.r.p. components) from the scalp. The e.r.ps triggered by verbal stimuli have been related to several different aspects of language processing[1]. For example, the N400 component, peaking around 400 ms post-stimulus, appears to be a sensitive indicator of the semantic relationship between a word and the context in which it occurs. Words that complete sentences in a nonsensical fashion elicit much larger N400 waves than do semantically appropriate words or non-semantic irregularities in a text[2,3]. In the present study, e.r.ps were recorded in response to words that completed meaningful sentences. The amplitude of the N400 component of the e.r.p. was found to be an inverse function of the subject's expectancy for the terminal word as measured by its 'Cloze probability'. In addition, unexpected words that were semantically related to highly expected words elicited lower N400 amplitudes. These findings suggest N400 may reflect processes of semantic priming or activation.

Late negative e.r.ps resembling the N400 have been observed in experiments that required subjects to make decisions about words based on their semantic attributes,[4–7] and Stuss *et al.*[8] noted an N400-like component following isolated, single words or pictures that required naming. One likely interpretation of these findings would assume that N400 amplitude reflects the extent to which a word is unpredictable or unexpected, regardless of whether or not it is incongruous with a preceding context. Since word expectancy influences how rapidly and accurately words are accessed, recognized and understood[9], a physiological index of this process would have considerable usefulness for revealing the structure of language comprehension mechanisms.

We examined this relationship by recording e.r.ps to words that completed sentences in a meaningful way but varied systematically in the degree to which they were expected. The sentences were selected from a set in which the degree of expectancy for alternative terminal words had been determined using the 'Cloze' procedure; that is, by requiring a large group of subjects to fill in the missing terminal word[10]. A word's Cloze probability is defined as the proportion of subjects using that word to complete a particular sentence. The experimental design called for words having different Cloze probabilities (hi, med, or lo) to be placed at the ends of sentences having one of three levels of contextual constraint (hi, med, or lo). Highly constrained sentences were those that led to very predictable endings, while sentences of low constraint did not induce such strong expectations (for examples see Fig. 1*A*).

A total of 321 sentences were presented, one word at a time, on a video terminal controlled by a microcomputer. Words were presented once every 700 ms for a duration of 132 ms. Fourteen subjects were instructed to read the sentences silently in order to answer a questionnaire about their contents at the end of the experiment. Scalp electrical activity was recorded using non-polarizable electrodes from frontal (Fz), central (Cz), parietal (Pz), and occipital (Oz) midline locations and from symmetrical sites over the anterior temporal (AT) and posterior temporal (PT) regions of the left (L) and right (R) hemispheres, each referred to linked mastoids. Eye movements and blinks were monitored via infraorbital and external canthal electrodes. The midline recordings were amplified with a bandpass of 0–40 Hz; the lateral recordings and electrooculogram with a 0.01–40 Hz bandpass.

The e.r.p. waveforms in Fig. 1*B* show that highly probable words at the ends of highly constrained sentences were followed by a broad, late positivity (hi/hi, solid tracing). In contrast, the low probability words elicited a posteriorly distributed negative

hi/hi	He mailed the letter without a stamp.
hi/lo	The bill was due at the end of the hour.
med/hi	She locked the valuables in the safe.
med/med	Too many men are out of jobs.
med/lo	The dog chased our cat up the ladder.
lo/hi	There was nothing wrong with the car.
lo/lo	He was soothed by the gentle wind.

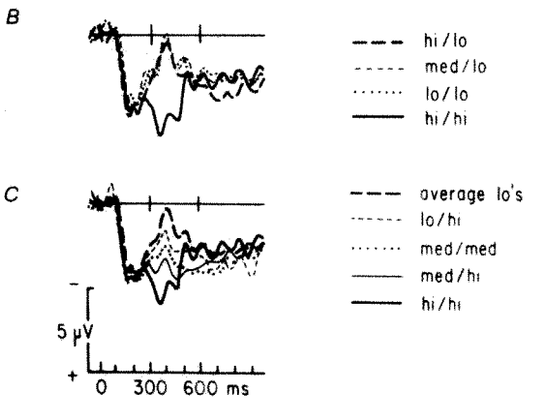

Fig. 1 *A*, An example from each of seven classes of sentences that varied in degree of contextual constraint and in the Cloze probability of the terminal word. There were 40–50 of each sentence type. On the left are shown the levels of contextual constraint/Cloze probability for each class. These two dimensions are not wholly independent, since only the more highly constrained sentences have the possibility of being terminated by words of very high Cloze probability. Thus, the level of Cloze probability considered to be 'hi' was relative to the level of contextual constraint, having average values of 0.92, 0.63 and 0.29 for the hi/hi, med/hi and lo/hi sentences, respectively. All of the low Cloze probability sentences, however, had average values of less than 0.03. *B*, Superimposition of grand average e.r.ps (across 14 subjects) from the Pz electrode to the low Cloze probability words terminating sentences of high, medium and low contextual constraint, together with the e.r.p. to high Cloze probability words completing highly constrained sentences. *C*, Grand average e.r.ps to terminal words of varying Cloze probability terminating sentences of high, medium and low contextual constraint. The e.r.p. to low Cloze probability words was averaged across the three levels of contextual constraint shown in *B*.

(best)	Don't touch the wet paint.
(unrelated)	Don't touch the wet dog.
(best)	He liked lemon and sugar in his tea.
(related)	He liked lemon and sugar in his coffee.

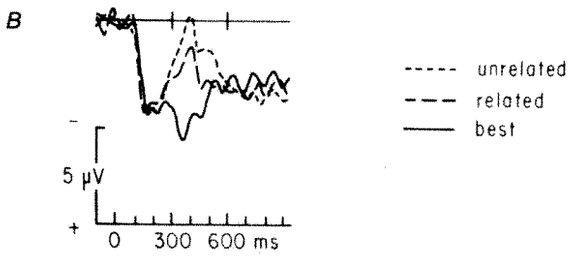

Fig. 2 *A*, Two examples of sentences with high contextual constraints completed by low Cloze probability words. Above each experimental sentence is the same sentence terminated by its 'best completion', which was or was not semantically related to the word that was actually presented in the sentence below. *B*, Grand average e.r.ps from Pz for the best completions (solid waveform), the semantically related (large dashed waveform) and the semantically unrelated (small dashed waveform) low Cloze probability words.

component (N400) that was superimposed upon the positive shift. The N400 amplitude to the low probability endings did not vary significantly over the three levels of contextual constraint (compare dotted and dashed tracings).

The N400 was measured as the mean amplitude over 300–500 ms post-stimulus, relative to a 50 ms prestimulus baseline. In general, the N400 amplitude was more sensitive to Cloze probability than to the degree of contextual constraint. For example, the e.r.ps to lo/hi versus med/med words, which were very similar in average Cloze probability (0.29 versus 0.23) but completed sentence fragments of low and medium constraint, respectively, did not differ significantly in N400 amplitude. On the other hand, comparisons of the e.r.ps to high, medium and low probability words terminating sentences of medium constraint revealed larger N400 amplitudes to the less probable words [main effect of ending Cloze probability $F(2,26) = 12.94$, $P < 0.001$; ending × electrode $F(14,182) = 6.07$, $P < 0.001$].

Inspection of the e.r.ps to all types of terminal words (Fig. 1*C*) revealed a gradient of potential, with the greatest positivity following hi/hi words and a progressively larger negativity (N400) elicited by words of decreasing Cloze probability. This relationship between Cloze probability and N400 amplitude was also evidenced by the product–moment correlations between the two measures across the seven classes of word endings [for the grand average e.r.ps, Fz, 0.80; Cz, 0.90; Pz, 0.92; Oz, 0.92; L.AT, −0.82; R.AT, 0.94; L.PT, 0.88; R.PT, 0.97]. At the parietal site, this correlation calculated from individual subjects' data averaged 0.70 (0.21) and reached significance in seven subjects (d.f. = 5, $P < 0.05$). This correlation also held when the e.r.p. data were collapsed across the different levels of contextual constraint and re-averaged according to the Cloze probability of the final words [Fz, 0.87; Cz, 0.91; Pz, 0.94; Oz, 0.92; L.AT, −0.60; R.AT, 0.75; L.PT, 0.91; R.PT, 0.93]. The negative correlation observed at the left anterior temporal site could result from this scalp region being located on the opposite side of the dipole field of the N400 generator.

The systematic decline in the N400 amplitude as a function of increasing Cloze probability indicates that semantic incongruity is not a necessary condition for N400 elicitation. Instead, N400 amplitude appears to vary systematically as an inverse function of word expectancy, operationally defined here in terms of Cloze probability.

The influence of context on word recognition has been attributed to the automatic priming or activation of semantic networks, as well as to slower, attention-directed processes[11–13]. Within such a framework, a sentence fragment primes (that is, activates for faster access) semantically related words whether or not they form acceptable sentence completions. In addition, sentence frames may result in the activation and retrieval of appropriate schemata[14–16]. If the N400 reflects some aspect of this semantic activation, its amplitude should vary according to whether or not an unexpected terminal words is semantically related to the most expected ending of that sentence (that is to the 'best completion' of the activated schema).

We tested this prediction by reanalysing the e.r.ps to low Cloze probability words that completed highly constrained sentences, now segregating them according to whether or not the terminal word was related to the best completion (BC) of the sentence in which it occurred. The degree of semantic relatedness had been determined by asking a different group of 25 subjects to rate each word pair on a 5-point scale. The mean ratings were 4.03 (0.70) and 1.95 (0.73) for the related and unrelated word pairs, respectively. Sample sentences are shown in Fig. 2*A*. N400 amplitude was indeed sensitive to the semantic relationship between the eliciting word and the expected best completion (Fig. 2*B*), with larger N400s following words that were unrelated to the BC [main effect of semantic relatedness

$F(1,13) = 17.37$, $P < 0.001$; relatedness × electrode $F(7,97) = 3.14$, $P < 0.001$].

These results are in agreement with the hypothesis that the N400 component reflects the extent to which a word is semantically primed, rather than its being a specific response to contextual violations. If the N400 amplitude proves to be a valid index of semantic priming, it should become possible to investigate the timing and spread of activation within semantic networks and knowledge schemata and to identify automatic and attentional components of processing.

Cell determination and regulation during development of neuroblasts and neurones in grasshopper embryo

Paul H. Taghert, Chris Q. Doe & Corey S. Goodman

Department of Biological Sciences, Stanford University, Stanford, California 94305, USA

The embryonic development of the central nervous system (CNS) involves the generation of an enormous diversity of cellular types arranged and interconnected in a remarkably precise pattern. In each hemisegment of the grasshopper embryo, the ectoderm generates a stereotyped pattern of 30 neuronal precursor cells, called neuroblasts (Fig. 1)[1]. Each of these stem cells makes a stereotyped contribution of 6–100 progeny to the ~1,000 different neurones, each cell identifiable according to its unique morphology, physiology and biochemistry. What are the contributions of cell interactions and cell lineage to the generation of this diversity and specificity of identified neurones in the grasshopper CNS? Here we report on cell ablations with a laser microbeam at different stages of development. Our results suggest the importance of cell–cell interactions in the determination of ectodermal cells to become identified neuroblasts[2]. However, once a neuroblast begins to divide, then cell lineage appears to play an important role in the determination of its stereotyped family of neuronal progeny[3]. Furthermore, cell-specific interactions continue to play an important role as neurones, according to their mitotic ancestry, recognize and interact with other differentiating neurones in their environment[4–6].

Within the neuroepithelium in each segment of the grasshopper embryo, there arise 61 neuronal precursor cells, called neuroblasts (NBs), arranged in two symmetric plates of 30 NBs each and one median neuroblast (MNB) (Fig. 1)[1]. We can identify each NB by its position within the neuroepithelium; moreover, many NBs can now be uniquely identified by the highly stereotyped family of identified neurones they produce[3,7–10]. Each NB is a stem cell which divides repeatedly to generate a chain of ganglion mother cells. Each ganglion mother cell then divides once more to generate two ganglion cells in a chain of cell doublets that then differentiate into neurones. The 30 NBs in each hemisegment largely generate the ~1,000 neurones in each thoracic hemiganglion and the ~250 neurones in each abdominal hemiganglion; most if not all of these neurones can be uniquely identified according to their characteristic morphology, physiology and biochemistry. The number of neuronal progeny appears to be specific for individual NBs; for example, NB 7–3 produces 6 progeny[10] whereas the MNB produces ~100 progeny[6–8]. Furthermore, the identities of the progeny appear to be specific for individual NBs; the fate of individual neurones is highly correlated with their specific positions in the family trees of particular NBs[6–10].

The progeny of NBs form coherent families of neurones that are inserted into the developing CNS in characteristic positions. The determination of an individual neurone might be due to its position in the NB family tree, or alternatively to its position in the developing ganglion and thus its reproducible interactions with its neighbours. Selective ablation of identified cells with a laser microbeam can help to distinguish between these alternatives. For example, NB 7–3 gives rise to six progeny (Fig. 1). In the abdominal segments (A4–A6), the first two NB 7–3 progeny are called S1 and S2; following their differentiation they can be specifically stained with an anti-serotonin antibody (Fig. 2). They are the only prominent serotonin-immunoreactive neurones in these segments. Furthermore, S1 and S2 can also be individually identified by their distinctive morphologies after intracellular dye injections (Fig. 1)[1]. We ablated NB 7–3 *in ovo* just before it begins its first cell division to test if some other NB could produce neurones with either the biochemical or morphological phenotypes of S1 and S2 (Fig. 2). We also ablated other NBs at the same stage to test if interactions with neighbouring NBs or their progeny were necessary for NB 7–3 to produce neurones S1 and S2.

NBs were identified in a 30%[11] embryo through the dechorionated eggcase under brightfield optics, and ablated with a pumped-dye laser (Fig. 2). Experimental and control embryos were examined at three different stages with three different techniques: at 33% with Nomarski optics to look for NB 7–3; at 50% with intracellular dye injections of Lucifer Yellow to look for cells with the distinctive morphology of neurones S1 and S2; and at 70% with the anti-serotonin antibody to look for cells with the distinctive serotonin-immunoreactivity of neurones S1 and S2.

When NB 7–3 was ablated before it began its first cell division and the embryos were assayed at 33% (the following day) for the presence or absence of the NB, we found that in approximately 80% of the cases ($n > 20$) no regulation took place. When regulation does occur, a new NB 7–3 is present as are all neighbouring NBs. When embryos were assayed at 70%, in 7 of 10 cases no serotonin-immunoreactive neurones were present on the experimental side of the ganglion (Fig. 2). In these embryos, the homologous S1 and S2 neurones from the contralateral NB 7–3 were always present and had the normal morphological and biochemical features. These observations suggest that when a NB is ablated before it begins its first cell division, regulation does not usually take place. In addition, progeny of neighbouring NBs do not differentiate with either the morphological or biochemical properties of neurones S1 or S2. The partial (20–30%) regulation we observe following NB ablation is likely to result from the recruitment of a neighbouring ectodermal cell, as described in the *in vitro* experiments below. In three other cases in which NB 7–3 was ablated, exhaustive intracellular dye injections at 50% of every other cell body in the region where S1 and S2 normally appear revealed no neurones with the distinctive morphology of S1 and S2 on the experimental side; S1 and S2 were easily found on the control side, and did

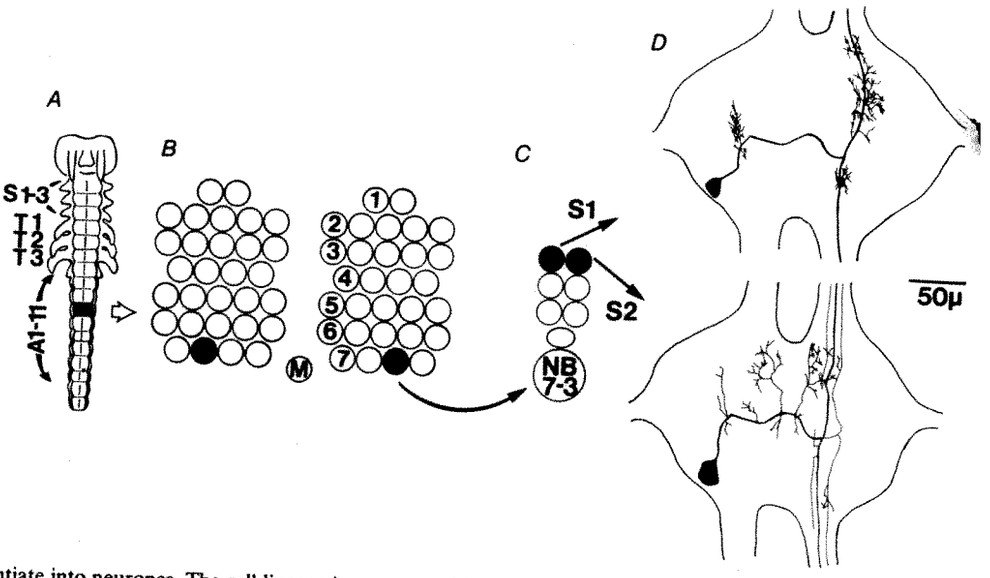

Fig. 1 *A*, Schematic diagram of a 30% grasshopper embryo[11] (hatching occurs at 100%) showing the segmental structure of the ectoderm. The middle of the ectoderm is a longitudinal strip of neuroepithelium which gives rise to the CNS. The location of the neuronal precursor cells for a single segment (A4) are drawn in black. *B*, Pattern of NBs for a single segment (A4) includes two plates of 30 NBs arranged in a precise pattern of seven rows, and one MNB making a total of 61 NBs. *C*, Cell lineage of the two identified serotonin immunoreactive neurones, S1 and S2, from NB 7–3 in segment A4. Cells S1 and S2 arise by an invariant cell lineage from the first division of NB 7–3. NBs generate neuronal progeny by a series of asymmetric cell divisions that produce small, ganglion mother cells. Ganglion mother cells then each divide once more symmetrically to produce two cells that will both differentiate into neurones. The cell lineage is represented here with a ganglion mother cell closest to the NB and older neuronal progeny lying progressively farther away from the NB. *D*, The cell-specific morphologies of neurones S1 (upper) and S2 (lower) in the A4 ganglion at 70% of embryonic development, as revealed by intracellular injection of Lucifer Yellow followed by HRP immunocytochemistry with an anti-Lucifer Yellow antibody[18].

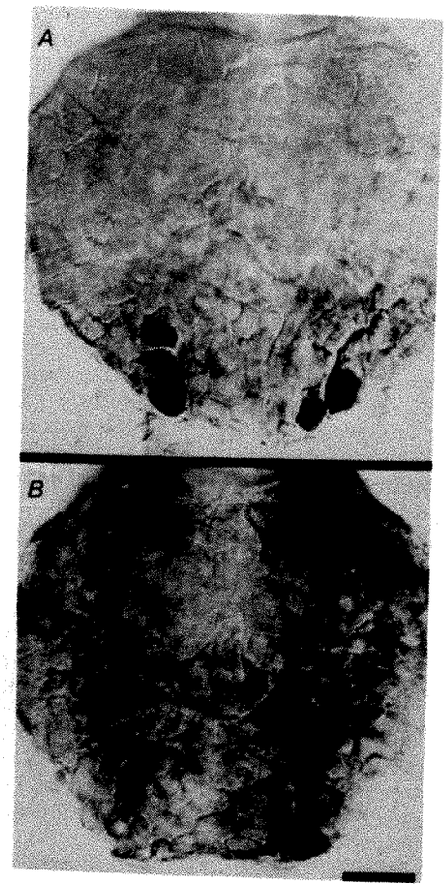

Fig. 2 Laser ablation of NB 7–3 *in ovo* before it began its cycle of cell divisions (30% of development) led to the absence of its identified progeny, neurones S1 and S2, in segment A4. *A*, Photomicrograph of an unoperated control ganglion stained in wholemount with the anti-serotonin antiserum at 70% of embryonic development. Note the bilaterally symmetrical immunoreactive cells, S1 and S2. *B*, Photomicrograph of a similarly stained ganglion in which NB 7–3 had been laser ablated earlier in development. Note the absence of immunoreactive cells on the operated side. Scale bar, 30 μm.

Methods: 30% Embryos were dechorionated in bleach, rinsed in saline and gently flattened with a coverslip to improve visibility of the NBs. NBs were identified through the dechorionated eggcase under brightfield optics with a Zeiss compound microscope using a Leitz 50× water immersion lens. Laser ablations were performed with a Chromaser pumped-dye laser system (Phase-R Corporation) using Coumarin 504 dye. Target cells were selected with a colinear helium-neon laser; 5 to 10 shots at ~250 mJ per shot over 5 to 10 min were used to kill NBs. Condensation of chromatin and subsequent loss of cellular integrity were seen within this time. Eggs were discarded given any sign of damage to neighbouring, non-target cells. Eggs with specific cellular ablations were removed from the slide and incubated. For serotonin immunostaining, the isolated embryonic CNS was fixed in 2% paraformaldehyde in Millonig's buffer and then processed according to the peroxidase–anti-peroxidase method of Sternberger[19]. Tissues were preincubated in 10% normal goat serum, 2% bovine serum albumin (BSA), and 1% Triton X-100 in phosphate-buffered saline (PBS) for 1 h. Tissues were then incubated in anti-serotonin antibody (Immunonuclear) at a 1:500 dilution, 1% normal goat serum, 1% bovine serum albumin and 1% Triton X-100 in PBS overnight at 4 °C. Following incubations in linking antibody and the peroxidase–anti-peroxidase antibody complex for 1 h each at room temperature, the tissues were developed for the horseradish peroxidase reaction product, cleared and examined.

not dye couple (as they normally do) to their homologues on the experimental side.

Not only does regulation not usually take place, but NB 7–3 appears determined to produce a particular family of neurones. Ablation of neighbouring NBs [for example, NB 6–5 ($n = 20$) which produces a small family, and NBs 7–2 and 7–4 ($n = 4$) which produce large families] did not appear to alter the morphological or biochemical differentiation of these first two NB 7–3 progeny as revealed with the anti-serotonin antibody. Furthermore, there was no apparent increase in the size of the NB 7–3 family to compensate for the loss of neighbouring families. Thus, cell lineage does appear to determine some aspects of cell fate in the insect CNS; NBs appear determined to produce particular families of neurones which differentiate with particular phenotypes.

But in what fashion does the precise pattern of identified NBs arise? Do they arise as a consequence of their cell lineage, as occurs for neuronal precursor cells in the nematode[12] and leech[13], or do they arise by cell–cell interactions, as occurs for the sensory neurone precursor cells in the epidermis of insects[14]?

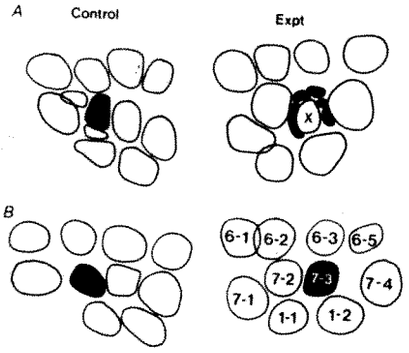

Fig. 3 *In vitro* laser ablation of ectodermal cell enlarging to become NB 7–3. Camera lucida drawings of NB rows 6 and 7 in segment T1, and NB row 1 in adjacent segment T2. *A*, A 26% embryo was removed from its eggcase under sterile conditions and viewed with a Zeiss compound microscope using Nomarksi optics and a Leitz ×50 water immersion lens for cell identifications. At the future position of NB 7–3 on the control side, the enlarging ectodermal cell (shaded) was allowed to develop normally, whereas its contralateral homologue (marked by X) was killed with three shots of the laser microbeam at 200 mJ per shot. This ablation left 5 smaller ectodermal cells (shaded) in the presumptive NB 7–3 position. The embryo was then cultured for 24 h in an RPMI 1640 culture medium containing glutamine (0.29 g l^{-1}), sodium pyruvate (0.11 g l^{-1}), penicillin (50 IU l^{-1}), streptomyocin (50 μg ml^{-1}), sodium biocarbaonate (2 g l^{-1}), horse serum (10%), glycine (6.0 g l^{-1}), bovine insulin (7.6 mg l^{-1}), 20-hydroxyecdysone (15 μg ml^{-1}), and juvenile hormone I (0.5 μg ml^{-1})[5]. Cultures were maintained in a moist incubator in a 5% CO_2 atmosphere at 29 °C. *B*, Camera lucida drawing of the same NB rows as in *A*, but after 24 h in culture. NB 7–3 (shaded) developed on both the control and experimental sides.

In insect embryos, gastrulation leads to an inner layer of mesodermal cells and an outer layer of ectodermal cells. It is from the seemingly uniform sheet of ectodermal cells between the midline and limb buds that the stereotyped pattern of NBs develops. Not all NBs form simultaneously. Initially, NBs arise from ectodermal cells that enlarge and delaminate inwards. Later, NBs arise from ectodermal cells that have delaminated to form clusters of small cells between the older NBs (Fig. 3). Ultimately, only one cell within each cluster enlarges and becomes a NB; the remaining cells either die or form ensheathing cells around the NB and sometimes its progeny. There are between three and six ectodermal cells in the region between NBs 7–2 and 7–4 from which NB 7–3 arises. To distinguish between cell lineage and cell-cell interactions in NB determination, we used a laser microbeam *in vitro* to ablate individual cells within the cluster of ectodermal cells from which NB 7–3 normally arises (Fig. 3)[2].

When we ablated the entire cluster of small cells, one of which would normally form NB 7–3, the NB did not appear ($n = 2$). When we ablated only a portion of the cluster, however, NB 7–3 formed. In particular, when we killed only the cell that was enlarging to become NB 7–3, regulation did take place ($n = 6$); one of the remaining cells became NB 7–3 (Fig. 3)[2]. The new NB 7–3 generated progeny by stereotyped asymmetric divisions, but embryos cultured *in vitro* did not develop far enough to determine the morphological or biochemical identity of these progeny. Apparently NB 7–3 can form from any one of the cells within the cluster, even after one cell has begun enlarging. Thus, cell–cell interactions within the cluster appear to determine which cell becomes the NB.

Our results demonstrate that at early stages no one cell is uniquely determined to be NB 7–3, but rather NB 7–3 develops from a restricted group of cells that share a common potential. Cell–cell interactions appear to assure that only one cell acquires the NB 7–3 fate. We do not know if the specification of individual NBs occurs in one step, or alternatively if an ectodermal cell first acquires a general NB determination and subsequently acquires a unique NB fate. By the time NB 7–3 begins its first cell division, however, it appears uniquely committed to generate a specific family of neurones; no other cell, including ectodermal cells adjacent to the ablated NB, can take its place. The NB 7–3 progeny cannot be replaced by progeny of neighbouring NBs. The final differentiation of each individual neurone depends on its mitotic ancestry and its later cell-specific interactions with other neurones in its environment[4–6].

These results suggest that the mechanisms giving rise to precursors for motoneurones and interneurones in the CNS are similar to those giving rise to precursors for sensory neurones[14] in the periphery of insects. Both types of precursors are derived from the ectoderm. Both undergo stereotyped patterns of cell divisions, the peripheral precursors typically generating four cells, one of which becomes a neurone, while the central precursors each generate 6–100 cells, all of which become neurones. The determination of both types of precursors appears to be based on position and not lineage, and involves cell–cell interactions that lead to an inhibition of surrounding cells from assuming similar fates. The differences are simply in the precision and complexity of the pattern. The central precursors develop in a highly stereotyped array while the peripheral precursors are more sparsely and often less precisely arranged. Moreover, while the peripheral precursors produce only a few different types of lineages (bristle, campaniform sensillum and so on), each central precursor appears to be uniquely determined to produce a specific lineage of neurones, each NB differing from the others in both the number and phenotypes of its neuronal progeny. Thus, the pattern formation in the CNS may involve a more complex form of the same mechanisms underlying pattern formation in the epidermis. Whether making the CNS involves more complex cell–cell interactions, or subdivisions of the ectodermal compartments[15–17] into smaller units than those required to generate the epidermis, remains to be tested.

We thank John Thomas for criticism of the manuscript. This work was supported by a NIH postdoctoral fellowship to P.H.T., NSF predoctoral fellowship to C.Q.D., and a NIH grant and McKnight Scholars Award to C.S.G.

Prostaglandin I_3 is formed *in vivo* in man after dietary eicosapentaenoic acid

Sven Fischer & Peter C. Weber

Medizinische Klinik Innenstadt der Universität München, Ziemssenstraße 1, 8000 München 2, FRG

Greenland Eskimos who live on a traditional marine diet rich in long chain ω3-polyunsaturated fatty acids have a low incidence of cardiovascular disease and myocardial infarction[1–3]. In their plasma and platelet lipids, arachidonic acid, the precursor of dienoic prostanoids, is partly replaced by eicosapentaenoic acid (C20:5, ω3; EPA), the precursor of trienoic prostanoids[4,5]. Studies with an Eskimo diet[6] or a

© 1984 Macmillan Journals Ltd

Western diet supplemented with sea fish or fish oil rich in EPA[7–14] resulted in an 'Eskimo-like' pattern of plasma and platelet lipids. Moreover, less reactive platelets, a reduced *ex vivo* formation of proaggregatory thromboxane A_2 and a blunted circulatory response to pressor hormones were reported. These favourable functional effects may be induced by a shift of prostanoid formation from the dienoic to the trienoic series[14,15]. We show here that the major urinary metabolite of endogenous prostaglandin I_3 is present in subjects that have ingested either cod liver oil (~4 g EPA per day) or mackerel (~10–15 g EPA per day). Our studies provide the first direct evidence for *in vivo* formation of prostaglandin I_3 in man.

In vitro experiments have shown that EPA-derived thromboxane A_3 (TXA_3), in contrast to arachidonic acid (C20:4, ω6; AA)-derived thromboxane A_2 (TXA_2)[16], does not[17,18] or only weakly[19] aggregate platelets, whereas EPA-derived prostaglandin I_3 (PGI_3)[15,18,20] is as antiaggregatory as prostaglandin I_2 (PGI_2)[21]. Consequently, a shift of prostanoid formation from the dienoic to the trienoic series may change the TXA/PGI balance[22] in a favourable way[15] (Table 1).

Previous studies have demonstrated formation of PGI_3 from exogenous EPA or endoperoxide PGH_3 in certain *in vitro* systems including rat arterial tissue[15], bovine and porcine aortic microsomes[18,23] and human umbilical arteries[24]. Tissue formation of trienoic prostaglandins has been found in bovine lung[25] and kidney homogenates from rats fed with fish oil[26]. The physiological significance of these findings has been uncertain because comparative studies using purified cyclooxygenase from sheep vesicular glands and AA and EPA as substrates[27] indicate that a high peroxide level, presumably not present *in vivo*, might be necessary for an appreciable formation of trienoic prostaglandins. Moreover, in other EPA feeding studies in the rat, tissue formation of PGI_3 was not detectable[28].

We addressed three major questions in this study: (1) Is there a substantial formation of PGI_3 *in vivo* in healthy man after a diet rich in EPA and is the intake of EPA associated with a decrease in PGI_2 formation? An analogous alteration has been found in platelet studies where EPA reduced formation of TXA_2 (refs 8, 14, 18). (2) Is there a quantitative relationship between the amount of EPA ingested, the induced changes of fatty acids in plasma phospholipids and the formation of PGI_2/PGI_3? (3) Are there changes in platelet aggregability, formation of TXA_2 and bleeding time after dietary EPA?

In our study we extracted, before and after dietary supply of EPA, dinor metabolites of PGI according to a highly selective method[29] from urine collected over 24-h periods. We used Δ17-2,3-dinor-6-keto-prostaglandin $F_{1\alpha}$ (PGI_3-M) as an index of total body production of PGI_3 in analogy to 2,3-dinor-6-keto-prostaglandin $F_{1\alpha}$ (PGI_2-M), which has been shown to be the major urinary metabolite of PGI_2 (refs 29, 30). A prerequisite for identification and quantification of PGI_3-M by mass spectrometry was its separation from PGI_2-M. This was achieved by using a capillary gas chromatography column with high resolving power. A partial mass spectrum of endogenous PGI_3-M extracted from urine after dietary intake of EPA is shown in Fig. 1. For comparison a partial mass spectrum of PGI_2-M simultaneously extracted from the same urine sample is presented below. The characteristically different fragmentation of PGI_3-M is due to the additional Δ17-double bond in this molecule. Fragments m/z 530 (M^+-69(71)), 440 (M^+-90-69(71)) and 350 (M^+-2×90-69(71)) are common to both metabolites, but are more intense in PGI_3-M, due to preferred allylic cleavage of the methyl side chain (C_{16}–C_{20}). Fragments m/z 584 (M^+-15), 568 (M^+-31), 478 (M^+-90-31) and 388 (M^+-2×90-31) are characteristic of PGI_3-M, but are less intense than fragments 586 (M^+-15), 570 (M^+-31), 480 (M^+-90-31) and 390 (M^+-2×90-31) which are characteristic of PGI_2-M. Some unidentified peaks in the spectra result from biological contaminating compounds in the urinary lipid extract which co-elute from the capillary column.

The multiple ion-selection tracings shown in Fig. 2 illustrate that PGI_3-M elutes from the capillary column about 35 s after

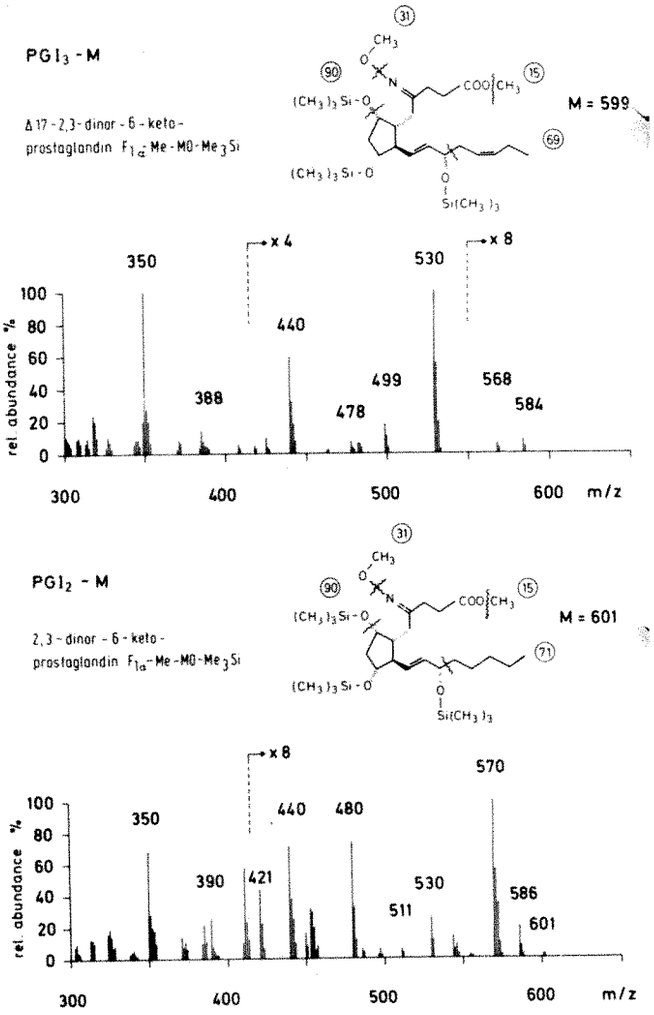

Fig. 1 Partial mass spectra (Me, MO, Me_3Si derivatives) of endogenous Δ17-2,3-dinor-6-keto-$PGF_{1\alpha}$ and 2,3-dinor-6-keto-$PGF_{1\alpha}$, the main urinary metabolites of PGI_3 and PGI_2, respectively. 800 ml of urine, collected after daily ingestion of 750 g mackerel for 3 days, were extracted according to the method of Falardeau *et al.*[29]. This method extracts the dinor metabolites of PGI_2 and PGI_3 highly selectively due to their ability to form γ-lactones in acidic solution. Extracts were methylated with ethereal diazomethane and further purified on silicagel TLC using the solvent system ethylacetate/isooctane/acetic acid/water = 110/50/20/100 (organic phase). The R_F value of authentic methylated 2,3-dinor-6-keto-$PGF_{1\alpha}$ was 0.24. The Me, MO, Me_3Si derivatives for GC-MS were prepared as described previously[29]. Prominent ions in the range above m/z 300 for Δ17-2,3-dinor-6-keto-$PGF_{1\alpha}$-Me,MO,Me_3Si are: 584 (M^+-15), 568 (M^+-31), 530 (M^+-69), 499 (M^+-69-31), 478 (M^+-90-31), 440 (M^+-90-69), 388 (M^+-2×90-31) and 350 (M^+-2×90-69); for 2,3-dinor-6-keto-$PGF_{1\alpha}$-Me,MO,Me_3Si: 601 (M^+), 586 (M^+-15), 570 (M^+-31), 530 (M^+-71), 511 (M^+-90), 480 (M^+-90-31), 440 (M^+-90-71), 421 (M^+-2×90), 390 (M^+-2×90-31) and 350 (M^+-2×90-71). The GC-MS system was a Finnigan MAT 44S equipped with a 50-m fused silica WCOT capillary column (Carbowax CP 51, 0.23 mm internal diameter; Chrompack), separating prostaglandins of the two and three series. Operation conditions of the GC-MS system were: injection port 280 °C; interface 270 °C; ion source 200 °C, electron impact energy 80 eV; current of emission 0.9 mA; electron multiplier voltage 1.8 kV.

PGI_2-M and is detectable only after dietary intake of EPA. Chemical reactions were performed to confirm the structure of PGI_3-M. Derivatization with methoxy-$^2H_3$-amine hydrochloride resulted in an increase of the molecular weight of PGI_2-M and PGI_3-M by 3 mass units and established the presence of one keto group in both molecules. Identity of PGI_3-M was confirmed by catalytic hydrogenation of the urinary extract.

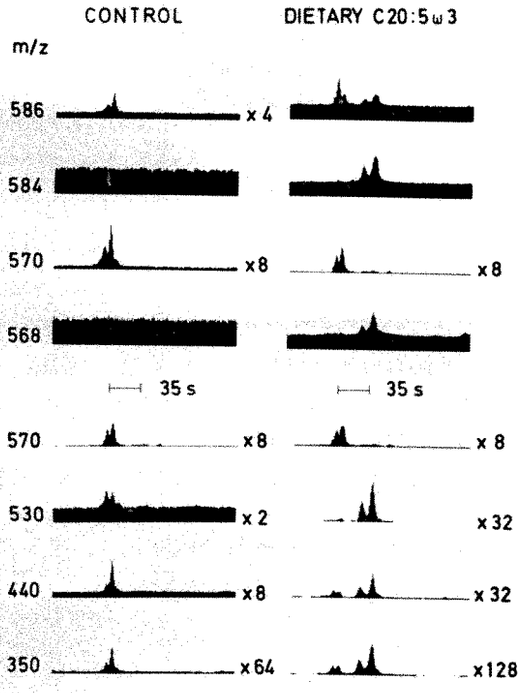

Fig. 2 Multiple ion-selection tracings (Me,MO,Me_3Si derivatives) of PGI_2-M extracted from a control urine (left) and of PGI_2-M and PGI_3-M extracted from a urine collected after daily ingestion of 750 g mackerel for 3 days (right). Qualitatively similar tracings were found after ingestion of cod liver oil. Double peaks are due to *syn*, *anti*-isomers formed by the methoxime group of the derivatives. A time axis indicates the elution time between both metabolites. Sensitivity of the tracings is lowered by the factors indicated and is adjusted to the highest occurring peak. Fragments 586 (M^+-15) and 570 (M^+-31) are specific for PGI_2-M, whereas analogous fragments 584 (M^+-15) and 568 (M^+-31) are specific for PGI_3-M. Fragments m/z 530 (M^+-69(71)), 440 (M^+-90-69(71)) and 350 (M^+-2×90-69(71)) are common to both metabolites. Deuterated internal standard (2,3-dinor-6-keto-19,19′,20,20′-^{2}H-$PGF_{1\alpha}$) for quantification of PGI_2-M has not been added to this sample.

Table 1 Physiological properties of the conversion products of arachidonic acid and eicosapentaenoic acid in vessel wall and platelets

Precursor acid	Arachidonic acid	Eicosapentaenoic acid

Patterns of polyunsaturated fatty acids (% of total fatty acids, mean ±s.d.) in plasma phospholipids and urinary excretion of PGI_2-M and PGI_3-M (ng per 24 h, mean ±s.d.) after intake of cod liver oil (40 ml ≙ 4 g EPA daily for 24 days; unchanged Western diet) or mackerel (750 g ≙ 10–15 g EPA daily for 3 days; no intake of other proteins or lipids). Fatty acids in plasma phospholipids were quantified by gas chromatography as described previously[8]. PGI_2-M and PGI_3-M were extracted simultaneously from urine according to the method of Falardeau *et al.*[29]. PGI_2-M was quantified by GC-MS using 2,3-dinor-6-keto-19,19′,20,20′-^{2}H-$PGF_{1\alpha}$ as the deuterated internal standard and monitoring the ion pair m/z 570/574 (M^+-31). The analysis was based on a standard curve which was shown to be linear in the observed range[34]. Excretion of PGI_3-M could not be quantified by GC-MS via a direct method due to lack of deuterated PGI_3-M or authentic unlabelled material. Quantification using deuterated PGI_2-M was also not possible because fragments suitable for multiple ion-selection represent different percentages of the total ion current of each molecule. Therefore, PGI_3-M excretion was quantified by an indirect method assessing at first the total excretion of PGI_2-M and PGI_3-M. This was achieved after catalytic hydrogenation of the urinary extract containing deuterated PGI_2-M as internal standard by monitoring the ion pair m/z 572/576 (M^+-31) of hydrogenated $PGI_{2,3}$-M and hydrogenated deuterium labelled internal standard (Me, MO, Me_3Si derivatives) which in their hydrogenated form represent compounds with identical fragmentation patterns. Urinary excretion of PGI_3-M was then calculated by subtracting the previously measured amount of PGI_2-M from the total amount of hydrogenated $PGI_{2,3}$-M. The method for quantification of urinary PGI_3-M was validated by a recovery experiment. Increasing amounts of PGI_2-M and a constant amount of deuterated PGI_2-M were added to a urine voided after mackerel ingestion. After hydrogenation of the urinary extract the added PGI_2-M was recovered quantitatively by GC-MS. Cod liver oil was manufactured by Møller A/S. All solvents and silicagel TLC plates were from Merck-Darmstadt. The 2,3-dinor-6-keto-$PGF_{1\alpha}$-lactone and the 2,3-dinor-6-keto-19,19′,20,20′-^{2}H-$PGF_{1\alpha}$ were a gift from Dr J. Pike (Upjohn). Methoxy-$^2H_3$-amine hydrochloride was prepared according to ref. 35. Catalytic hydrogenation was performed in the presence of Rh/charcoal in ethyl acetate.

* $P<0.01$; † $P<0.05$ compared with control values.

A single new compound was formed from PGI_2-M and PGI_3-M with a molecular weight of m/z 603, corresponding to an uptake of 1 and 2 equivalents of hydrogen, respectively. This substance co-chromatographed on capillary gas chromatography with authentic hydrogenated PGI_2-M and exhibited identical fragments with analogous intensities.

Table 2 summarizes the analyses of ω3 and ω6 polyunsaturated plasma phospholipid fatty acids and the urinary excretion rates of PGI_2-M and PGI_3-M after two separate studies with different amounts of dietary EPA. Polyunsaturated plasma phospholipid fatty acids indicated a characteristic change. Whereas EPA increased drastically during both dietary regimens, C22:6, ω3 was elevated significantly only after ingestion of cod liver oil due to the higher content of this fatty acid in cod liver oil as compared with mackerel. AA only decreased slightly after cod liver oil or mackerel ingestion, whereas C18:2, ω6 was strongly reduced after these dietary regimens. The more pronounced decrease of C18:2, ω6 in plasma phospholipids during the mackerel diet probably resulted from the complete substitution of animal and vegetable ω6-fatty acids by ω3-fatty acids of the mackerel. Excretion of PGI_3-M was not detectable in control conditions, but was clearly measurable after intake of cod liver oil and increased with increasing EPA incorporation into plasma phospholipids, reaching levels one-half of those

measured for PGI_2-M. The content of EPA in plasma phospholipids and the urinary excretion rates of PGI_3-M were elevated within 1 day of mackerel ingestion and increased only slightly thereafter. This may indicate that endothelial cells rapidly equilibrate with the plasma lipids and thereby transform EPA to PGI_3, as has been shown for PGI_2 from AA[31]. Our results also show that dietary EPA does not inhibit *in vivo* formation of PGI_2 from AA, confirming similar results from *in vitro* studies using human unbilical vasculature and AA and EPA as substrates[32]. Excretion of PGI_2-M was unchanged (cod liver oil) or even increased (mackerel) under the influence of dietary EPA. The reason for the increase of PGI_2-M excretion after mackerel ingestion is unclear. According to observations in endothelial cell cultures[33], the drastic decline of C18:2, $\omega 6$ in plasma phospholipids after mackerel ingestion may contribute to an increased prostacyclin synthetase activity in endothelial cells.

We have previously shown that platelet aggregation induced by low concentrations of collagen and associated formation of immunoreactive TXB_2 are reduced after a diet of mackerel in healthy subjects[8]. In the present study also, we found that ingestion of cod liver oil (CLO) for 25 days resulted in a reduced platelet aggregation (measured as % light transmission) in platelet rich plasma on stimulation with low doses (0.75 $\mu g\ ml^{-1}$) of collagen (control, $70 \pm 5\%$ (s.d.); CLO, $53 \pm 15\%$; $P < 0.01$). Concomitantly, a reduced formation of immunoreactive TXB_2 in collagen stimulated platelets (control, $40 \pm 13\ ng\ ml^{-1}$; CLO, $15 \pm 2.5\ ng\ ml^{-1}$; $P < 0.01$) and an increase of bleeding time (control, 104 ± 34 s; CLO, 145 ± 52 s; $P < 0.01$) were observed. Furthermore, in recent experiments[36] we have traced by combined gas chromatography–mass spectrometry (GC-MS) *ex vivo* formation of weakly proaggregatory TXA_3 in human platelets after supplementation of the diet with cod liver oil. Thus, the reduced platelet aggregability, increased bleeding time and reduced blood pressure response to pressor hormones[14] after dietary EPA may be due to formation of PGI_3 and TXA_3 associated with a reduced synthesis of TXA_2 and an unchanged or even increased formation of PGI_2.

Our findings with a diet rich in EPA prove that it is possible in man to change the spectrum of biologically highly active prostanoids by nutritional means and alter it in a favourable direction. This may be a mechanism by which EPA-enriched diets induce a less thrombogenic state and hence may be beneficial for the prevention of atherothrombotic disorders.

We thank Drs B. Scherer, R. Lorenz and W. Meister for cooperation, Dr C. von Schacky for performing parts of the fatty acid analyses and U. Katzner for technical assistance. This study was supported by Deutsche Forschungsgemeinschaft.

Reconstitution with syngeneic plus allogeneic or xenogeneic bone marrow leads to specific acceptance of allografts or xenografts

Suzanne T. Ildstad & David H. Sachs

Transplantation Biology Section, Immunology Branch, Cancer Institute, National Institutes of Health, Building 10, Room 4B17 Bethesda, Maryland 20205, USA

Clinical organ transplantation between genetically disparate individuals currently requires the use of chemotherapeutic agents to suppress the rejection reaction. The deleterious side effects of these reagents and their inability to prevent rejection completely has led to a continuing search for methods to induce specific transplantation tolerance in adult recipients. Numerous experimental animal models utilizing irradiation and bone marrow transplantation coincident with organ transplantation have been proposed[1–4]. Bone marrow transplantation, however, has its own major complications, including graft–versus-host reactions and immunoincompetence, probably resulting from a failure of appropriate immune cell interactions in the reconstituted host[5,6]. We have now attempted to overcome these difficulties by reconstituting the irradiated host with T-cell depleted bone marrow containing both host (syngeneic) and donor (allogeneic or xenogeneic) components. This technique leads to long-term survival of the reconstituted animals and specific prolongation of subsequent skin grafts of donor type. Animals reconstituted in this fashion are fully reactive to third-party allografts and xenografts and do not appear to manifest signs of graft–versus-host disease.

Inbred mice of the congenic strains C57BL/10Sn (B10) and B10.D2/nSn (B10.D2) (Jackson Laboratory, Bar Harbor) and rats of strains F344 and Wistar Furth (WF) (Charles River Laboratories) were used. Recipient B10 males were given a single dose of 950 rad from a caesium source. Donor bone marrow was treated with rabbit anti-mouse brain antiserum (RAMB) and guinea pig complement to remove mature T lymphocytes as previously described[7].

Titrations were performed to determine the optimal number of syngeneic and allogeneic or xenogeneic bone marrow cells needed to achieve consistent reconstitution and tolerance. The experiments described here were performed with a dose of 5×10^6 syngeneic cells and either 1.5×10^7 allogeneic B10.D2 bone marrow cells or 4×10^7 xenogeneic F344 rat bone marrow cells. Bone marrow preparations were treated separately *in vitro* with RAMB plus complement and were then washed, counted and mixed just prior to inoculation through the tail vein. Animals were subsequently housed in a specific pathogen-free facility at the National Institutes of Health.

The survival of B10 animals reconstituted with B10 plus B10.D2 bone marrow was 100% at 100 days and 88% at 200 days, which is essentially identical to the survival of B10 animals reconstituted with syngeneic bone marrow (data not shown). All irradiation control animals died within 2 weeks. Cytotoxicity

* % Lysis was that obtained by mouse anti-rat serum plus complement minus complement control.

† % Of cells with fluorescence intensity greater than 300 on log scale following staining with mouse anti-rat serum and fluorescein isothiocyanate conjugated goat $F(ab)_2$ anti-mouse IgG preparation (FITC-GAMIG) minus % staining with FITC-GAMIG alone. Animals were subjected to partial splenectomy, and splenic lymphoid suspensions were stained with mouse anti-rat antiserum and a FITC-GAMIG. NT, not tested.

typing of peripheral blood lymphocytes[8] of reconstituted animals demonstrated persistence of both host- and donor-type lymphoid cells at 60–120 days following reconstitution (Table 1). These animals therefore represent mixed allogeneic chimaeras.

Animals were grafted with full thickness skin grafts from donor and third-party allogeneic strains of mice approximately 12 weeks after reconstitution, using a modification of the method of Billingham[9]. Rejection was considered complete when no clearly viable graft could be detected. Eighty-six per cent of mixed allogeneic chimaeras were tolerant to donor-type skin grafts, showing complete survival of fully viable skin grafts for more than 145 days (Fig. 1). The tolerance was specific, since third-party allogeneic skin grafts were rejected with a median survival time essentially the same as that of unirradiated controls.

B10 recipient mice reconstituted with a mixture of syngeneic and xenogeneic F344 rat bone marrow cells also demonstrated long-term survival similar to that of syngeneically reconstituted animals (86% survival at 100 days). In contrast to the mixed allogeneic chimaeras, peripheral blood lymphocyte typing of mixed xenogeneically reconstituted animals at day 60–70 following reconstitution revealed low numbers, if any, of donor lymphoid cells in the peripheral blood of these animals (Table 2). Further analysis of these animals was performed by flow microfluorometry (FMF) using the fluorescence-activated cell sorter (FACS)[10]. Control experiments showed that 0.5% contaminating rat lymphoid cells could reliably be detected. The number of rat lymphoid cells detectable in spleens of mixed xenogeneically reconstituted mice was very small, ranging from 0–2.26% (Table 2).

Nevertheless, these animals appeared to be specifically hyporeactive to donor-type F344 rat skin grafts (Fig. 2). Fourteen B10 animals reconstituted with mixed syngeneic and xenogeneic F344 rat bone marrow cells were grafted with both F344 and B10.D2 skin grafts 75–85 days following irradiation and reconstitution. Rat skin grafts exhibited signs of inflammation beginning 2–10 weeks following grafting. This inflammation often subsided, but eventually recurred in all animals and led either to late rejection or contraction of the skin graft to a small but viable residual. However, all of the animals showed prolonged survival of the rat skin grafts (median survival time [MST] > 50 days) compared with normal B10 animals, which

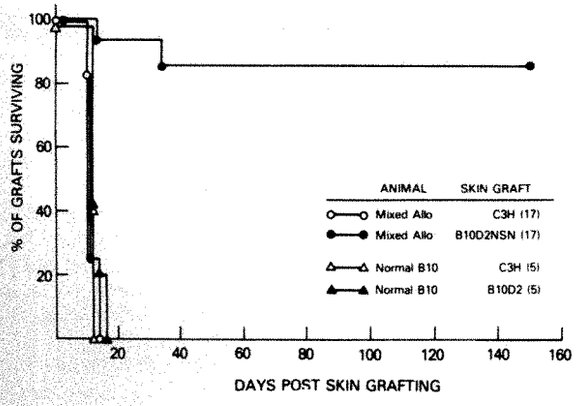

Fig. 1 Survival of B10.D2 and C3H full thickness tail skin grafts on lateral thoracic wall of mixed allogeneic chimaera (B10+B10.D2→B10) and controls calculated by life table method.

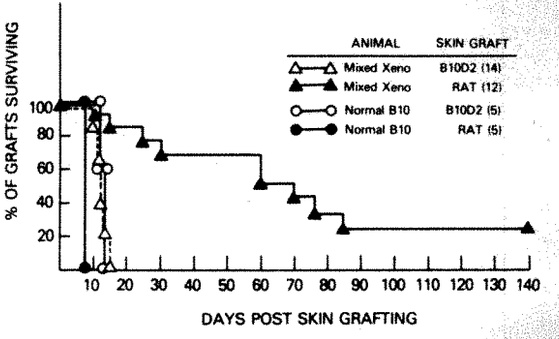

Fig. 2 Survival of F344 rat and B10.D2 full thickness tail skin grafts on lateral thoracic wall of mixed xenogeneic chimaeras (B10+F344 rat→B10) and controls calculated by life table method. Fourteen reconstituted animals were grafted with both rat and B10.D2 skin grafts, but only 12 of the rat skin grafts were technically successful and could be evaluated.

rejected F344 rat skin grafts in less than 9 days. Furthermore, these same animals rejected the third party allogeneic B10.D2 skin grafts with an MST identical to that of normal B10 controls. This result has subsequently been confirmed in two additional groups of mice. In one of these groups, an additional skin graft was performed from a WF rat, a rat strain differing from the F344 at both major and minor histocompatibility loci[11]. The WF skin grafts were all rejected promptly, while the F344 skin grafts again showed the same prolonged survival.

Numerous previous studies[7,12,13] have shown that elimination of mature T cells from donor bone marrow inocula can lead to long-term survival of fully allogeneic bone marrow chimaeras. However, the survival of such animals is generally not as good as that of syngeneically reconstituted controls, and the health of these animals is compromised, probably as the result of partial immunoincompetence[5,6]. The model for fully xenogeneic chimaeras[14] has been less extensively studied than that of allogeneic chimaeras. In our experience, such animals show prolonged survival over irradiation controls, but all succumb within a few weeks following reconstitution. It is not clear whether the death of these animals is due to a chronic graft–versus-host disease, or to infectious complications secondary to partial immunoincompetence.

In contrast, the studies presented here indicate that reconstitution with mixtures of syngeneic bone marrow and either allogeneic or xenogeneic marrow leads to long-term survival of recipients equivalent to that of syngeneically reconstituted animals. The animals have remained healthy and have shown no evidence of infections or of graft–versus-host disease for longer than 3 months.

Typing of mixed allogeneically reconstituted animals at 2–3 months following reconstitution showed them to be truly mixed chimaeras, bearing variable percentages of syngeneic and allogeneic lymphoid cells in their peripheral circulation. Such animals are immunocompetent[13] and specifically tolerant to donor skin grafts. In mice reconstituted with mixed syngeneic and xenogeneic bone marrow, we have found little evidence for persistence of the xenogeneic lymphoid compartment. However, these animals also appear to be specifically hyporeactive to subsequent skin xenografts. They may be more similar to neonatally induced allochimaeras[15], in which only very small numbers of persistent donor-type cells can be found[16]. Since the survival of skin grafts is frequently more difficult to prolong than that of most other foreign tissues[17], it seems likely that animals manifesting this level of hyporeactivity to skin grafts would be highly tolerant to xenografts of kidneys, hearts and other solid organs.

These data therefore indicate that reconstitution of lethally irradiated mice with mixtures of syngeneic and either allogeneic or xenogeneic bone marrow leads to the induction of specific immune unresponsiveness to subsequent donor skin grafts. The mechanism of this specific unresponsiveness may not be the same in these mixed allogeneic and xenogeneic models, and further mechanistic studies both *in vitro* and *in vivo* are presently in progress. Both types of reconstitution offer models which may be directly applicable to organ grafting in other species, including man.

We thank Dr Hugh Auchincloss Jr for helpful discussions, Mr David Stephany for performing the FACS analysis, Ms Judith Jaworek for manuscript preparation, and Ms Susan O. Sharrow and Drs David Tollerud, Richard Hodes and Mark Peskovitz for review of the manuscript.

Genetic evidence of X–Y interchange in a human XX male

Albert de la Chapelle*, Patricia A. Tippett†, Gunilla Wetterstrand‡ & David Page§

* Department of Medical Genetics, University of Helsinki, 00290 Helsinki 29, Finland

Of the hypotheses put forward to explain why occasional individuals with two X chromosomes are nonetheless male, the one that has attracted most attention is the possibility[1] that one of the X chromosomes has obtained a small piece of Y chromosome which is sufficient to produce 'maleness'. This hypothesis was based primarily on the observation that in two families with XX males[2–4] both fathers were Xg(a+) and both probands Xg(a−). (*Xg* shows X-linked dominant inheritance.) This theory holds that an anomalous X–Y interchange at meiosis in the father resulted in the paternal X chromosome's losing the *Xg* gene and acquiring a male-determining gene from the Y chromosome. While, for example, the frequencies of Xg phenotypes among XX males[5,6] and the cytogenetic observation of a structural abnormality in one X[7,8] are compatible with this hypothesis, direct evidence of it is lacking. Here we describe an XX male who expresses his father's allele for 12E7, a Y-linked marker, but fails to express his father's allele for Xg, an X-linked marker. These findings strongly suggest that anomalous X–Y interchange occurred in this case and perhaps in that of many other XX males. We suggest that a male-determining gene on the Y has also been translocated to the X and caused maleness in the proband. These results are discussed in the light of current models of X–Y chromosomal homology.

A boy born in 1980 had slightly dysmorphic facial features but was otherwise normal. He has remained in good health but his physical growth is greatly retarded (at 2 yr and 3 months old, height = 75 cm, weight = 7.4 kg). His height development is well below the 2.5 percentile for boys and even for girls. Clinical and laboratory investigations had failed to disclose anything abnormal to account for the retarded growth until a karyotype showed him to be 46, XX; there was no evidence of mosaicism in the two tissues karyotyped (lymphocytes and skin fibroblasts). The parents (born in 1953) are non-consanguineous. All four grandparents are alive. The proband has a brother born in 1978 and a sister born in 1983. All family members are healthy.

All family members (Fig. 1) were tested for the following blood groups: ABO, MNSs, P_1, Rh, Lu^a, Kell, Lewis, Duffy, Kidd, Dombrock and Co^b. That II-1 is indeed the father of III-2 is supported by the inheritance of these markers (data not shown). Figure 1 shows the segregation of the blood group Xg, the antigen 12E7, and the polymorphic X–Y homologous DNA locus designated *DXYS1* (ref. 9) in the members tested. Both parents, II-1 and II-3, are Xg(a+); the mother is heterozygous Xg^aXg as her father, I-3, is Xg(a−). Both the proband, III-2, and his brother, III-1, are Xg(a−) so they have received the maternal *Xg* gene. All Xg(a+) individuals express high levels

0028–0836/84/020170—02$01.00

© 1984 Macmillan Journals Ltd

of 12E7 (ref. 10). However, in families with Xg(a−) members, the quantitative polymorphism of 12E7 expression shows Y-linked inheritance[11]. For example, 77 Xg(a−) high-level 12E7 males (first tested member of sibship) have 110 Xg(a−) younger (or tested later) brothers of whom 107 have high-level 12E7 and 3 have low-level 12E7 expression; 18 Xg(a−) low-level 12E7 males have 19 Xg(a−) younger brothers of whom 17 have low-level 12E7 and 2 have high-level 12E7 expression. These comparisons give $\chi^2 = 20.51$ and 15.81 respectively if 12E7 were not Y-controlled. The five exceptional brothers could be the result of X–Y interchange, or of difficulties in testing travelled red cells, or of a different father (the father of only one of the exceptions has been tested)[11].

In the family reported here, both the paternal uncle, II-2, and elder brother, III-1, are Xg(a−) and high expressors of 12E7, suggesting that the Y chromosome in the paternal family carries Yg^a. (The Y-linked *12E7* locus has been designated *Yg* on the basis of its hypothesized homology to *Xg*[10]. The allele for high expression of 12E7 has been designated Yg^a.) The maternal grandfather, I-3, is Xg(a−) low 12E7 and, therefore, *XgYg*.

The proband does not carry the paternal Xg^a allele but has received a gene producing high 12E7 expression. As this could not have come from the mother, the most straightforward explanation is an interchange of the *Xg* and *Yg* loci in paternal meiosis. As a consequence of this, the X chromosome of paternal origin has lost its Xg^a but acquired Yg^a. The presence of testes and male differentiation in the proband is probably the consequence of a sex-determining gene having been exchanged as well. Perhaps a male-determining gene normally located in proximity to *Yg* on the Y chromosome has been translocated to the X. Alternatively, an X-borne gene involved in sex determination may have been lost or inactivated.

Our interpretation assumes that one of the proband's X chromosomes is indeed paternal. The *Taq*I restriction fragment length polymorphism at the *DXYS1* locus shows normal segregation of the Y-specific 15-kilobase (kb) fragment with the Y chromosome in the father, II-1, and brother, III-1 (Fig. 1). The proband has a double dose of the X-specific 11-kb allele (one from the father and one from the mother). This is not formal proof of the paternal derivation of one X, as it is also consistent with the proband having two copies of the maternal X carrying the 11-kb allele (and *Xg*). However, the latter possibility is inconsistent with the 12E7 data. The segregation of eight additional X-linked DNA polymorphisms was examined in this family but none of the polymorphisms proved to be informative with respect to a paternal contribution (data not shown).

It has been shown recently that many XX males have one paternal and one maternal X chromosome. When the segregation of the *DXYS1* alleles was tested in six families, four were informative. In each of these four cases the XX male proband was heterozygous[11,12] while the mother was homozygous for one of the alleles and the father hemizygous for the other (D.P. and A. de la C., unpublished results). This supports the notion that one X is paternal in many, if not most, XX males.

The proposed interchange explains three findings (loss of Xg^a, acquisition of Yg^a, maleness) as the consequence of one event. The alternative—non-disjunction at maternal meiosis plus non-disjunction at the first paternal meiotic division or zygotic loss of the Y—does explain the chromosomal and Xg data but fails to explain the level of 12E7 expression and the maleness of the proband. Hence, the interchange mechanism must be considered the most likely one.

At present we do not know what proportion of XX males arises by the type of interchange that occurred in this case. That it may be common is suggested by the fact that at least nine families are known in which the XX male proband apparently did not inherit his father's *Xg* allele[6]. Furthermore, the frequency of Xg phenotypes in XX males is close to that of XY males and is significantly different from that of females (R. Sanger and P.A.T., unpublished observations on 94 northern European XX males).

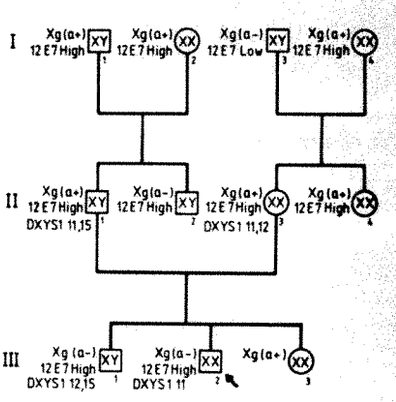

Fig. 1 Pedigree of the family showing the sex chromosome constitution and segregation of the blood group Xg, the antigen 12E7, and the X–Y homologous DNA locus *DXYS1*.

In contrast, at least five families are known in which the XX male proband did inherit his father's *Xg* allele[6]. These cases either arose by another mechanism or the interchange involved different regions of those chromosomes. Light and electron microscopic evidence[12,13] indicates that terminal portions of the short arms of the human X and Y chromosomes normally pair at male meiosis. It has been suggested that crossing-over within this 'pairing region' occurs as a normal event[1,14–16], but there is no genetic evidence for this. Here we have described a clearly anomalous meiotic interchange of normally X-linked and Y-linked markers. Of note is the fact that the *Xg* gene maps to the 'pairing region' on the X[17] while a *12E7* structural gene maps to the euchromatic portion of the Y[18], which includes the pairing region. Thus, the X–Y interchange reported here may be an example of a common event, but one which is abnormally proximal to the centromere.

The aetiology of XX males is probably heterogeneous. The underlying mechanisms may include errors of X-chromosome inactivation, mutations in autosomal or X-chromosomal genes, and X–Y interchange (probably with different breakpoints in different cases). A somewhat analogous finding is that the sex reversal mutation in the mouse (*sxr*) is now known to be due to a complicated Y–X exchange[19,20].

This study was aided by grants from the Sigrid Jusélius Foundation, the Nordisk Insulinfond, the Academy of Finland, the NIH (USA), and the Wills Foundation. We thank Dr Peter Goodfellow for the anti-12E7 antibody and Drs David Botstein and Arlene Wyman for critical reading of the manuscript.

‡ Hospices Civils, 67000 Strasbourg, France

In humans, XX maleness is the best known example of a sex reversal syndrome occurring with an incidence of one XX male among approximately 20,000 to 30,000 newborn boys[1–4]. The karyotypes of the majority of these individuals are apparently normal, with respect to the numbers and structure of the chromosomes, but is in contradiction with the phenotypic sex which they display. XX maleness may be either a non Y-related mechanism triggered by a mutation on another chromosome[3–5] or could be the result of the expression of some cytogenetically undetectable Y chromosome material present in the genome of such individuals. Recently, a number of human Y-specific single copy probes have been isolated[6,7]. In this study, using several of these Y-specific probes we definitively demonstrate the presence of Y-chromosomal material in the genome of some 46,XX human males. These XX males carry only a fraction of the human Y chromosome. In the three positive cases reported here, presence of inclusive overlapping chromosomal fragments has been detected, implying a genetic heterogeneity of these patients.

The 4 cases of XX male analysed are sporadic with no familial incidence of genetic intersexuality. Their clinical and biological features are summarized in Table 1. DNAs from cloned lymphoblastoid cell lines or lymphocytes originating from the four different human XX males have been digested with *Eco*RI, *Hin*dIII or *Taq*I, fractionated and blotted onto DBM-cellulose paper[8]. The DBM papers were successively hybridized to different probes detecting Y-specific DNA fragments. Under stringent hybridization conditions these probes detected single copy DNA fragments whereas under less stringent conditions additional bands are sometimes observed that are not strictly homologous. In order to detect a maximal number of Y-specific bands, low stringency washing conditions have been used in this survey whenever possible. Figure 1 shows the hybridization pattern of two probes 52d and 50f2 to *Taq*I digests. Probe 52d (Fig. 1*A*) detects three Y-specific bands in normal XY DNAs and a small X-located fragment[7] not present in this figure. Two out of the three Y-specific fragments are also present in XX males 1 and 4 indicating the presence of Y chromosomal DNA in some XX males. Since the third Y-specific band does not appear in these cases (1 and 4), we conclude that the Y chromosome is not present as a whole. Confirmation of this result is obtained with probe 50f2 (Fig. 1*B*). This probe detects 1 autosomal band at 12 kilobases (kb), in both male and female DNA, and in addition, four Y-specific fragments. Here again, only 2 out of 4 of the Y specific bands are present in the same patients 1 and 4.

The data on the Y-specific sequences, tested as probes on genomic blots of XX males, are summarized in Table 2. Out of the four individuals, only three reacted with the probes used (case 1, 3 and 4). The three positive cases did not react to the same extent with the probes tested. Although case 1 and 4 reacted with six and five probes respectively, case 3 reacted only with probe 47c. This observation implies that these XX male patients each contain a different amount of Y-chromosomal DNA and thus exhibit a genetic heterogeneity. In all three cases, the same subset of Y-specific bands was detected, implying presence of overlapping chromosomal fragments. The genome

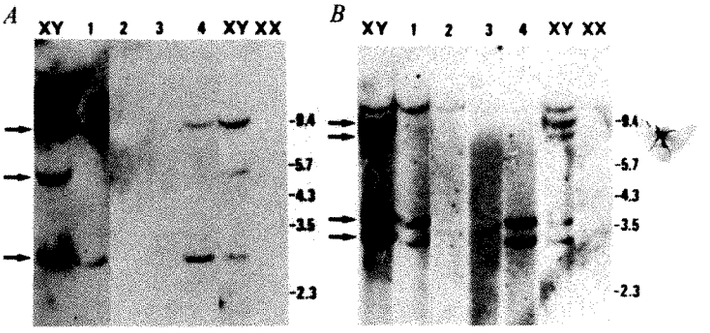

Fig. 1 DNA was extracted as previously described[6,7] from lymphocytes of normal individuals or from cloned lymphoblastoïd cell lines derived by Epstein–Barr virus transformation of lymphocytes from XX males. The probes were derived from a partial Y chromosome library as previously reported[6,7]. The genomic blot used in *A* and *B* was prepared by digesting genomic DNA to completion with *Taq* (Bio Labs) used according to manufacturers' specifications, separating on 1% agarose gels and transferring to DBM paper. Normally 15 μg of DNA was used per lane. The DBM paper blots were hybridized[8] with 30×10^6 c.p.m. per blot of the probes 52d (*A*) or 50f2 (*B*) (10^8 c.p.m. μg^{-1}) and washed under non-stringent conditions (2×SSC; 68 °C; 2×60 min). Exposure of the film was done for various times at −70 °C in the presence of an intensifying screen. XY: normal male; XX: normal female; 1–4: different XX males. The male specific bands are arrowed on the left of the two panels. The size of the markers is indicated in kilobase pair units on the right.

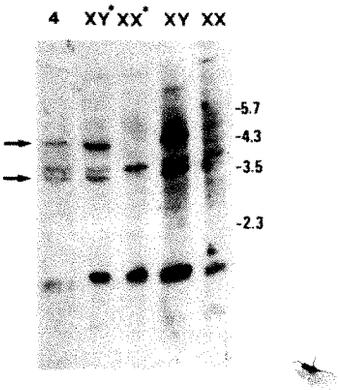

Fig. 2 The experiment was performed as for Fig. 1. The five DNAs were hydrolysed with *Hin*dIII, the genomic blot hybridized with probe 47c and washed under non-stringent conditions. XY* and XX* are the parents of case 4, XY and XX: normal male and female.

of case 1 contains the most numerous Y DNA fragments. These fragments completely overlap with the fragments present in case 4 which themselves overlap with the fragments of case 3. This totally inclusive overlapping could be observed by chance, but it is also consistent with an involvement of one of the telomeric parts of the Y chromosome. If, in addition, one assumes that only a single Y-chromosomal piece is present in the genome of these XX males, blocks of overlaps can be positioned with reference to a common origin and the distance of a DNA fragment from this origin is inversely related to the frequency of this fragment in XX males. This would represent the first attempt to order Y DNA fragments by deletion mapping.

Since the probes described here also hybridize to non-Y material, the possibility exists that the fragments detected in XX males are due to a restriction fragment length polymorphism of this non-Y material. This possibility can be rejected in view of the following arguments: (1) the non-Y bands are still present in the expected amount in the XX males according to hybridization intensity, (2) all the putative Y bands in the XX males appear exactly at the same level as in normal males (Fig. 1) and in different restriction digests (not shown). It is practically impossible that, by chance, restriction length polymorphism could have resulted in numerous bands all of the exact same size as the Y-specific ones.

The parental origin of the Y-specific fragment could be assessed further for case 4. Figure 2 represents a genomic blot

0028-0836/84/020172—02$01.00

Table 1 Clinical and biological summary of the 4XX males analysed

	Case 1	Case 2	Case 3	Case 4
Age (yr)	21	11	22	20
Sterility	Azoospermy	NT	Azoospermy	Azoospermy
Testes	Small	Extremely reduced	Small	Small
Gynaecomasty	Absent	Absent	Absent	Absent
Histopathology of the gonad	NT	Testicular structure without germ cells, with Sertoli cells	Testicular structure without germ cells, with Sertoli cells	Testicular structure without germ cells, with Sertoli cells
FSH level	High	High	High	High
Testosterone level	Low	Very low	Low	Low
Karyotype	XX	XX	XX	XX
H-Y	Present	Present	Present	Present

Karyotype and H-Y determination[15] were performed on lymphoblastoïd cell lines and peripheral lymphocytes. Similar results were obtained with both types of cells. NT, not tested. In all the four cases, at least 200 mitoses were analysed both on peripheral lymphocytes and lymphoblastoïd cell line obtained by Epstein–Barr virus transformation of B lymphocytes. Trypsin band (G banding) and Q banding were performed. No Y material could be detected and both X chromosomes appear of normal size. Familial blood groups, including HLA antigen were performed. No exclusion of paternity was observed. Xg anomalous segregation were found for cases 2 and 3 and will be described elsewhere. For the two other cases, the Xg phenotype was not informative.

of *Hin*dIII restriction enzyme hydrolysis of case 4 along with DNA from his parents (asterisk) and normal male and female DNA. Hybridization to probe 47c reveals an identical pattern between case 4, XY* and XY, and a total absence of male specific bands on the DNA of the mother(XX*). This result excludes maternal inheritance of the Y-chromosomal DNA in this case.

It is generally thought that the mammalian Y chromosome is the bearer of a male sex determining locus[1,2]. It is reasonable to conclude that this putative locus is present in the piece of Y chromosome detected in XX male patients. In case 3 only a single Y specific fragment has been detected. This suggests that only a small part of the Y chromosome is present and that this part is sufficient for controlling essential steps of the male gonadal sex determination.

This study represents the first unambiguous molecular evidence for the presence of Y DNA material in some human XX male genomes. Furthermore, it also proves that only a part of this chromosome is present and this is probably the reason for the absence of its detection by cytogenetical means. These results can be related to the recent explanation of the sex reversal mutation in mouse[9,10]. However, it should be pointed out that in man this syndrome is mainly sporadic, whereas in mouse, the *Sxr* mutation is genetically transmissible by affected XY males[11]. In the aetiology of human XX maleness, the Y chromosome is mainly involved in two hypotheses: translocation of a piece of Y chromosome and hidden mosaïcism. Since the number of mitoses usually examined in karyotyping studies is relatively important, the cytogenetical approaches would certainly remain more sensitive for the detection of a mosaïcism.

The form in which this Y chromosome DNA is present in XX males is at present unknown. The most probable explanation involves a translocation event and as reported elsewhere, the X chromosome is the most likely candidate[12–14]. X–Y interchange can even be suspected in case 3 where an anomalous segregation of the Xg blood marker has been observed (M. Fellous, unpublished results).

One patient (case 2) remained negative in this survey, it is not known if this is related to the fact that this case displayed the most severe hypogonadism. Since it is very difficult to know if all the regions of the Y chromosome are covered by our probe collection, presence of Y material cannot therefore be excluded in negative cases for the moment. In the near future, it should be possible, with the availability of more Y-specific probes, to discriminate unambiguously between putative true XX males and XX males bearing Y DNA material.

We thank Professor P. Tiollais for his support, C. Johnsson and A. Abadie for technical assistance, F. Latron for the karyotyping and H-Y studies; DNA samples and DBM blots have been shared with J. L. Mandel whose help is gratefully acknowledged; we are also very grateful to Professor Roy and Dr Caporal for their help and collaboration; C.E.B. was in receipt of a Joliot-Curie grant. This work was supported by INSERM grant PRC 135012 and CRL 814030, DGRST 870346 and by the Fondation de la Recherche Médicale.

Table 2 Male specific bands in the genome of XX males

Probe	Normal male	XX males 1	3	4
47c	2(T)	2	2	2
50f2	4(T)	2	—	2
52d	3(T)	2	—	2
48	1(H)	1	—	1
118	8(T)	4	—	4
27	1(T)	1	—	—
64a7	1(E)	—	—	—
37c	1(E)	—	—	—
49f	3(T)	—	—	—
12f3	1(T)	—	—	—
Male repetitive* probe	1(E)	—	—	—

DNA, genomic blots and hybridization procedures are as depicted in the legend of figure 1. The results refer to the number of male specific bands present on a *Taq* (T), a *Hin*dIII (H) or an *Eco*RI (E) blot. Following hybridization, a low stringency of washing was used (see Fig. 1) except for probes 64a7, 37c, 49f, and the repetitive probe which were hybridized under high stringency (0.1×SSC instead of 2×SSC).

* Repetitive probe refers to male specific 3.4 kb *Hae*III fragment[16].

The establishment and maintenance of pregnancy using *in vitro* fertilization and embryo donation in a patient with primary ovarian failure

Peter Lutjen, Alan Trounson, John Leeton, Jock Findlay*, Carl Wood & Peter Renou

Department of Obstetrics and Gynaecology, Monash University, Queen Victoria Medical Centre and *Medical Research Centre, Prince Henry's Hospital, Melbourne, Australia 3000

Ovarian steroid replacement therapy in the ovariectomized ewe, given in the correct sequence to mimic endogenous steroid changes in the normal ovulatory cycle, allows the development of embryos transferred *in utero*[1-3]. A similar type of sequential therapy was designed for steroid replacement in women with primary ovarian failure. This produces the histological changes in uterine endometrial morphology and plasma oestradiol and progesterone similar to those observed in the normal ovulatory cycle[4,5]. We now report that in one of these women a donated oocyte[6], fertilized by her husband's spermatozoa[7] and cultured to the two-cell stage *in vitro*, was transferred *in utero*, resulting in a normal pregnancy and the delivery of a healthy child. Oestrogen therapy was withdrawn at 12 weeks and progesterone at 19 weeks gestation. This technique allows the treatment of human infertility due to primary ovarian failure.

The recipient was a 25-year-old married woman complaining of 5 years of amenorrhoea following withdrawal from contraception. Endocrine investigations throughout this period had shown continually depressed urinary oestradiol excretion on 24 separate occasions and continually elevated plasma gonadotropins in the postmenopausal range (follicle stimulating hormone, luteinizing hormone > 30 IU l^{-1}), indicative of primary ovarian failure. Treatment with both human chorionic gonadotropin (β-HCG, 3,000 IU per day for 3 days) and a combination of ethinyloestradiol and progesterone failed to elicit any detectable ovarian response in terms of oestradiol production. The patient presented with characteristic 'hot flushes' and vaginal dryness, indicative of her hypo-oestrogenic state. Secondary sexual development appeared normal and her karyotype (G banded) was normal (46 XX). Both thyroid and adrenal functions were assessed and were normal. Diagnostic laparoscopy at 20 years of age revealed marked ovarian atrophy and complete absence of follicular development. An ovarian biopsy showed an absence of primordial follicles. At 25 years of age the patient commenced ovarian steriod replacement with the intention of receiving a donated embryo.

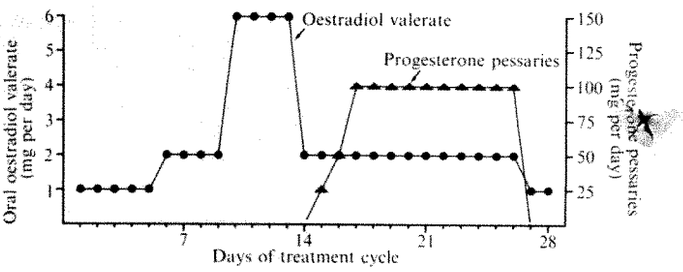

Fig. 1 Dose regime for the cycle replacement of oestrogen and progesterone. Oestradiol valerate was taken orally at 24-h intervals, at doses of 1 and 2 mg per day (days 1–9 and 14–28) or at 8-h intervals at a dose of 6 mg per day (days 10–13). Progesterone was administered as a single 25 or 50 mg intravaginal pessary once a day (days 15–16) or two pessaries introduced separately at 12-h intervals (days 17–26).

The regimen of ovarian steroid replacement with oral oestradiol valerate (Progynova, Schering) and intravaginal progesterone pessaries is given in Fig. 1. The treatment was formulated to mimic as closely as possible the ovarian steroid profile throughout a normal 28-day ovulatory cycle[5]. On the completion of the 28th day of steroid replacement, the patient recommenced therapy at day 1 and repeated this treatment in a cyclic manner.

Peripheral plasma oestradiol and progesterone levels were monitored during the third treatment cycle and on the 16th day a single two-cell embryo was transferred to the patient[8]. Oestrogen and progesterone replacement was continued, as shown in Figs 2 and 3. Following embryo transfer, progesterone pessaries were replaced by intramuscular progesterone injections (Proluton, Schering) for the remaining period of steroid therapy.

Using procedures described previously for embryo donation[6], a single oocyte was inseminated with spermatozoa prepared from a semen sample from the recipient's husband[7]. The donor of the oocyte was a 29-yr-old woman whose infertility was due to bilateral tubal blockage. Five oocytes were obtained from the donor during an *in vitro* fertilization treatment cycle and

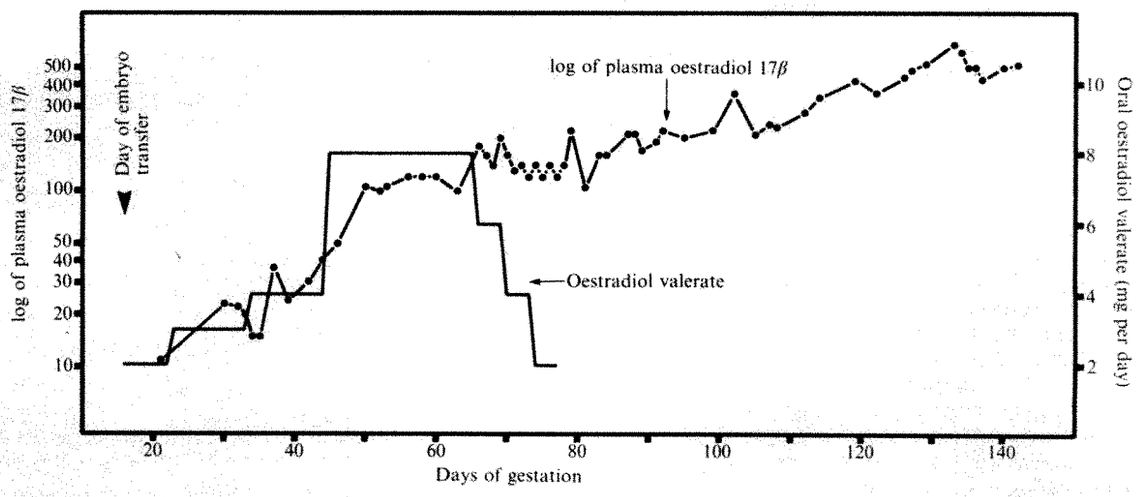

Fig. 2 Oestradiol valerate replacement therapy following embryo transfer and plasma oestradiol-17β levels (●) during pregnancy. Doses of 2 mg per day were taken at 24-h intervals, 3 and 6 mg at 8-h intervals, and 4 and 8 mg per day taken at 6-h intervals.

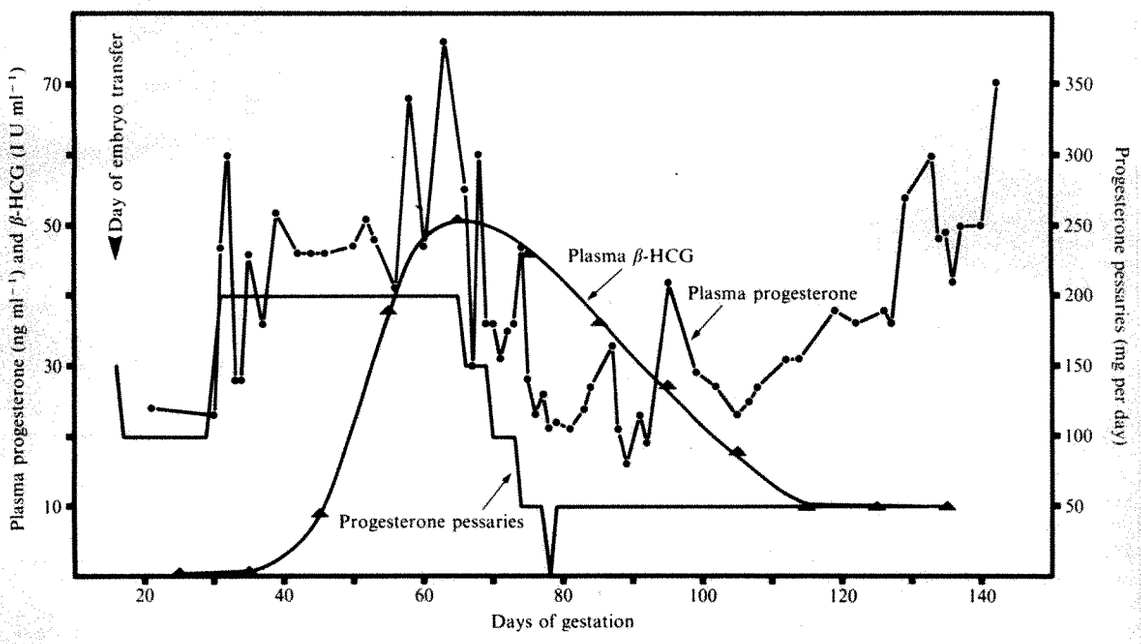

Fig. 3 Intramuscular progesterone (Proluton, Schering) replacement therapy following embryo transfer and plasma progesterone (●) and endogenous β-HCG (▲) levels during pregnancy. Doses of 50 mg per day were given at 24-h intervals, 100 mg per day at 12-h intervals, 150 mg per day of 8-h intervals and 200 mg per day at 6-h intervals.

she and her husband consented to donate one oocyte to the recipient couple. The donor failed to become pregnant on the cycle of IVF treatment after transfer of four of her own two-cell embryos *in utero*.

Pregnancy was confirmed in the recipient by normal changes in β-HCG (Fig. 3). The dosage of oestradiol valerate and progesterone administered was altered to keep the patient's peripheral plasma levels of these hormones in the normal range for pregnancy (Figs 2, 3). Ultrasonic reports on the fetus and placenta at 8, 12, 17 and 28 weeks of gestation were normal. Oestrogen therapy was withdrawn at 12 weeks' gestation. Progesterone therapy was unable to be completely withdrawn until 19 weeks because plasma progesterone levels declined to below the normal levels expected in pregnancy when withdrawal was attempted at 12 weeks.

The pregnancy continued normally until 38 weeks of gestation when a healthy baby boy was delivered by elective caesarean section. HLA-AB typing using peripheral blood lymphocytes in a standard microlymphocytotoxicity assay excluded the recipient as the biological mother and verified the association of the baby with the donor. The establishment and maintenance of pregnancy in the present report confirms our hypothesis[6] that in women with primary ovarian failure, progesterone and oestradiol can be used successfully as replacement therapy for the establishment and maintenance of pregnancy following transfer of donor embryos. In these women, there is no other treatment for their infertility. Prior to this successful case, we had transferred embryos to six patients, given similar or slightly modified steroid hormone treatments without success.

Shortly after the pregnancy was established, the Premier of the state of Victoria requested the cessation of all work involving donated oocytes to allow consideration of the social, ethical and legal issues of gamete donation in IVF by a state government appointed committee. The committee's recommendations in favour of continuing the work were reported in September 1983[9]. However, the state government has not revoked the moratorium and, as a consequence, we have not been able to continue the research programme and repeat the successful procedure described.

During the preparation of this paper a report was published on the establishment and maintenance of pregnancy in ovariectomized monkeys given ovarian steroid implants[10]. Future studies in this area need to determine whether sequential therapy designed to mimic normal endocrine levels in the ovulation cycle is essential for the establishment of pregnancy, as studies in sheep have demonstrated[1-3], or whether a simplified steroid therapy regimen may be used. The use of synthetic progestagens instead of progesterone would also simplify hormone replacement therapy for the patients. Pregnancy may be limited to the synchronous transfer of particular cleavage stage embryos on specific days of the treatment cycle. More flexibility of the timing of oocyte donation and embryo transfer would be achieved by embryo cryopreservation[11]. Legal and ethical difficulties encountered with embryo donation[6] will be satisfied if governments adopt recommendations such as those proposed in Victoria[9].

We thank all the members of the Monash-Epworth Infertility Unit and Department of Obstetrics and Gynaecology for helpful advice and assistance, and Dr Brian Tait of the Royal Melbourne Hospital for HLA typing. Progesterone and Proluton were provided by Schering Ltd.

Similar level of polyteny in bands and interbands of *Drosophila* giant chromosomes

Anne Spierer & Pierre Spierer

Department of Molecular Biology, University of Geneva, 30, quai Ernest-Ansermet, 1211 Geneva 4, Switzerland

The giant polytene chromosomes of *Drosophila melanogaster* have long been of interest to the geneticist because of the visible map of the genome provided by their characteristic banding patterns[1]. An issue in the understanding of the molecular basis of chromosome banding has been whether the chromosomal DNA is replicated to the same extent in bands and interbands. Although various suggestions have been put forward the point has remained controversial[2–5]. We have isolated 315 kilobases (kb) of contiguous *Drosophila* genomic DNA[6] which spans an interval of approximately 13 bands and interbands of the polytene chromosomes[7]. We report here the measurement of the relative level of DNA replication in polytene chromosomes of 84 adjacent restriction fragments of our cloned DNA. We conclude that there are no significant differences in the level of polyteny within the large band and between bands and interbands of this region. This result supports the 'folded fibre' model of polytene chromosome organization[8], rather than models involving disproportionate replication along the banding pattern[2–4].

The 315 kb of chromosomal DNA sequence that we have isolated includes 13 ± 1 chromomeric units (band and adjacent interband) of sizes ranging from about 3 to 160 kb, and 12 recessive lethal complementation groups[7]. To detect any local variation in polyteny we decided to measure the relative DNA replication level in polytene chromosomes of 84 fragments representing this interval by quantitative Southern blot hybridizations[9,10]. Two control experiments checked that this method can quantitate single copy sequences in genomic DNA. A reconstruction experiment demonstrated that the autoradiographic signal is indeed proportional to the relative abundance of a unique restriction fragment in a genomic background (Fig. 1). In a second control, the sensitivity of the method was tested *in vivo*, with a heterozygous deletion ending within the chromosomal walk. Single copy fragments within the deletion produced about half the signal that was seen with wild-type DNA or when compared with probes outside the deletion (Table 1). From these experiments and from tests of reproducibility (not shown), we felt confident that any local change in polyteny larger than twofold from the mean could be detected.

Table 1 Quantitative Southern blot hybridizations distinguish one dose from two doses of a single-copy sequence within genomic DNA

Probe[7]	Fragment size (kb)	Signal ratio (wt/ry^{614})	Mean of ratios
2189	3.1	0.42	0.46
	1.9	0.39	
	1.5	0.56	
2849	1.7	1.0	0.93
	1.4	0.78	
	1.1	1.0	

Wild-type chromosome: 2849 — 2189

Df(3R)ry^{614}/wt

2 μg of wild-type genomic DNA and 4 μg of DNA from the heterozygous deletion Df(3R)ry^{614} (refs 7 and 13) were digested with *Eco*RI, size-separated on agarose gels and transferred to nitrocellulose. Filters were hybridized to the recombinant 2189[6] or 2849[6]. The autoradiographic signals were measured by scanning densitometry. The position of the two probes relative to the deletion breakpoint is shown schematically under the table.

DNA was prepared from polytene tissue (salivary glands from third instar larvae) and from diploid tissues (embryos). Parallel tracks of equal amounts of 'polytene' and 'diploid' DNA digested with restriction enzymes were transferred to nitrocellulose paper and hybridized to a set of probes representing the walk. The signal could thus be expressed for each fragment as a 'polytene/diploid' ratio. A second calibration step was to hybridize all the filters to the same probe, to correct them for unequal loading or differences in transfer efficiency. This probe (2148)[6] was arbitrarily chosen as providing a polytene/diploid ratio of 1.0. The filters were then recycled and re-used with other probes to span the whole chromosomal walk. Figure 2 shows autoradiographs of eight filters hybridized to eight different segments of the walk and to the calibration segment. We also took the precaution not to quantitate fragments larger than 5 kb, for they are frequently under-represented in DNA preparations of salivary glands because of shearing (our unpublished observations). The complete results are shown diagrammatically in Fig. 3. Each of the 84 dots represents the level of replication of a restriction fragment and its position on the walk; an artist's view

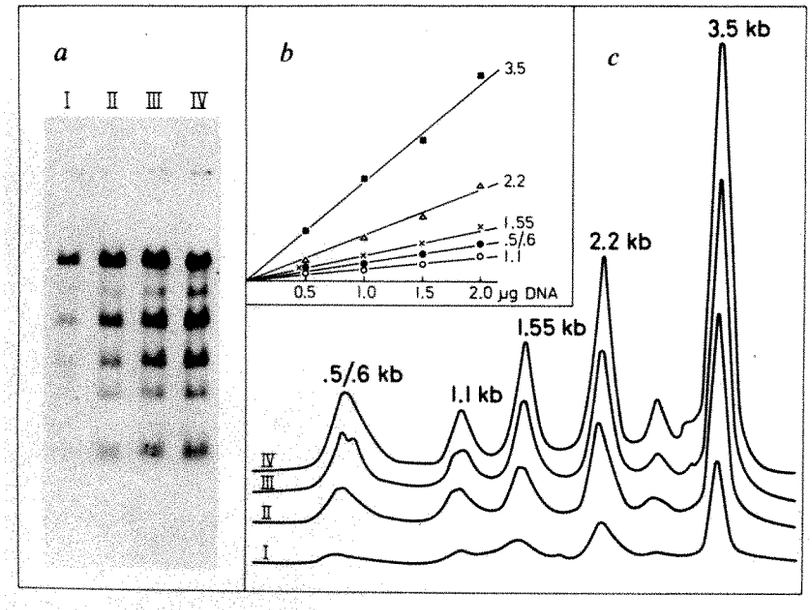

Fig. 1 Densitometry of autoradiographs of genomic Southern blot hybridizations does measure single copy restriction fragments. *a*, 0.5 μg (I), 1.0 μg (II), 1.5 μg (III) and 2.0 μg (IV) of *Drosophila* embryonic DNA brought to 2.0 μg with salmon sperm DNA were digested with *Eco*RI, size separated on 0.9% agarose gels and transferred to nitrocellulose. Filters were hybridized to the nick-translated recombinant 2160[6], which comprises only single copy sequences, and autoradiographed. *b*, Plot of the heights of peaks [cm] obtained by scanning microdensitometry (*c*) of autoradiographs in *a*, as a function of *Drosophila* DNA concentration.

© 1984 Macmillan Journals Ltd

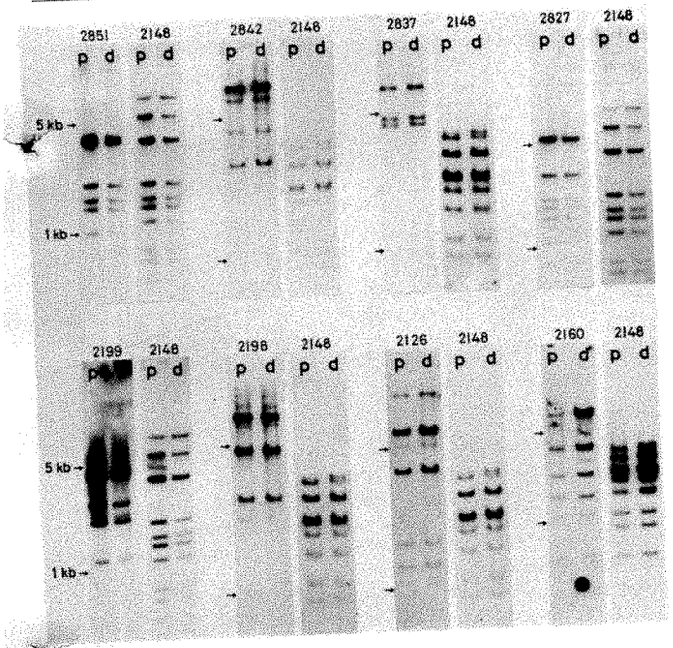

Fig. 2 Autoradiographs of genomic Southern blot hybridizations of polytene and diploid DNA with different segments of the walk. Polytene DNA was prepared from hand-dissected salivary glands of third instar larvae while diploid DNA was from embryos (0–16-h old). DNAs were digested with *Eco*RI (2842, 2837, 2198, 2126, 2160) or with *Bam*HI and *Hin*dIII (2851, 2827, 2199). Polytene (p) and diploid (d) DNAs were size-separated on parallel tracks of agarose gels and transferred to nitrocellulose. Filters were hybridized firstly to 2148[6] for calibration and then to other probes whose positions on the walk are indicated in Fig. 3. The arrows indicate the 5-kb size (top) and 1-kb size (bottom). For each pair of panels, the panel on the right shows the calibration hybridization with 2148[6] (equivalent to 2146 in Fig. 3); the panel on the left is the hybridization of the same filter to one of the segments of the walk. Filters were recycled by soaking in 0.1 M NaOH for 3 min at room temperature. The importance of this calibration is visible in the 2851 measurement: the signal is fainter in the diploid track to the same extent in the 2851 and in the 2148 hybridizations. Intensities and sizes of bands are as expected for unique sequences. Fainter bands are seen when the probe overlaps only partially with the fragment (5-kb and 11-kb fragments in 2126, for example) or in a few cases because of partial digests. Partial digestion, however, represents always less than 10% of the full digest (as seen on scans) and, hence, does not contribute significantly to the results. Heavier than expected bands are due to superposition of fragments of the same size (bands of about 4.5 kb in 2851, and of about 2.3 kb in 2148 digested by *Eco*RI for example).

of the polytene chromosome banding pattern is aligned with the DNA sequence map. The mean of the ratios for the 81 unique fragments is 0.97. The values range from 0.55 to 1.56 with a standard deviation of 0.25.

We see no local change in the level of polytenization, for no value goes beyond the 50% over or under-replication which we would consider significant. The large band 87E1,2 extends over 160 kb in the central part of the walk[7]. The relative abundance of about 35 fragments was measured in this interval, thus showing that there is no significant variation of level of DNA replication across this large band. The left part of the walk covers 9 ± 1 bands and interbands in 85 kb. The resolution at which we can place bands and interbands on the DNA map in this region does not allow us to tell whether particular restriction fragments are made of band or interband DNA[7]. However, cytological measurements of interband length led Beermann[5] to estimate that their average DNA sequence content is about 2 kb. Therefore, the 9 ± 1 interbands of the region spans about 18 out of the 85 kb of sequence and should be largely represented in the set of 26 fragments (mean size 2.6 kb) which were measured. We conclude that there is no large variation of polyteny among bands and interbands, and within a large band in this interval. Finally replication models in which bands and interbands have different levels of replication require that dormant replication forks are aligned at the band/interband boundaries. This should change the appearance of restriction fragments on genomic Southern blots. The genomic restriction pattern, however, was identical in polytene and diploid DNA all along the walk (not shown except the eight examples in Fig. 2).

Our study of a typical segment of the chromosome comprising bands of all sizes suggest that monotonous polyteny along the euchromatic arms of polytene chromosomes is a general feature. This is supported by the recent observation that a set of cloned sequences arising from different chromosomal locations have a similar level of replication in polytene chromosomes[11]. Chromosomal constrictions may, however, be the unavoidable exceptions to the rule. Lyfschitz[11] found that the cluster of histone genes close to or within the constriction at 39D is under-replicated. We have determined that the bithorax complex of homeotic genes[12] which spans the 89DE constriction is also under-replicated in polytene chromosomes (P.S., A.S. and W. Bender, unpublished results).

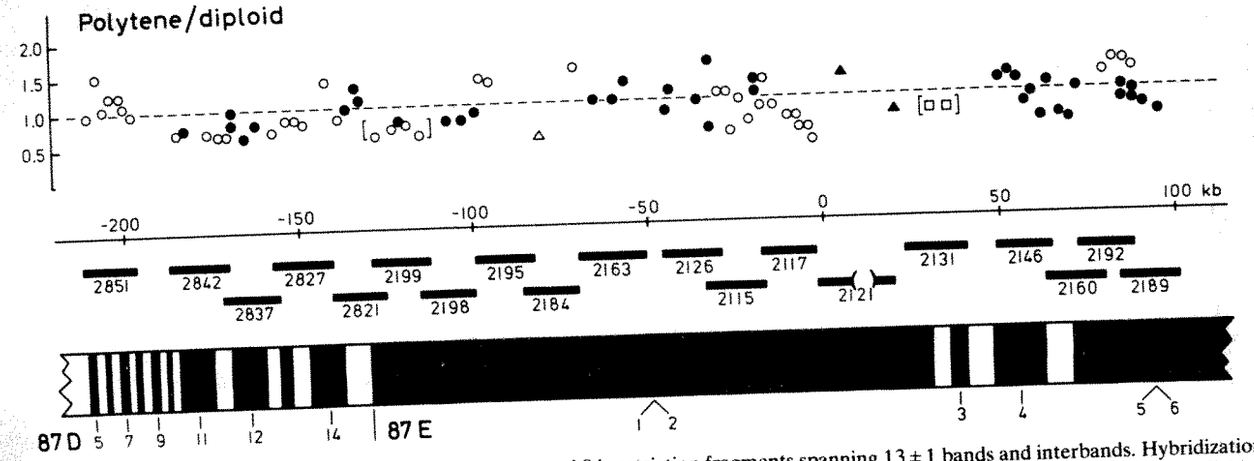

Fig. 3 Relative level of replication in polytene chromosomes of 84 restriction fragments spanning 13 ± 1 bands and interbands. Hybridizations were as in Fig. 2. The position of the probes is indicated with solid bars, and their numbers refer to ref. 6. Polytene/diploid ratios of individual restriction fragments are plotted as a function of their DNA map position. Calibration steps are explained in the text. The banding pattern is schematically aligned with the DNA map as described in ref. 7. ○, Fragments resulting from *Bam*HI and *Hin*dIII combined digestion; ●, fragments from *Eco*RI digestion; △, ▲, fragments larger than 5 kb, digested with *Bam*HI/*Hin*dIII or *Eco*RI respectively, when no smaller fragment could be used; □, fragments from *Bam*HI/*Hin*dIII which may contain moderately repeated sequences (not shown). Order of fragments in parentheses has not been determined. When two fragments co-migrated in gels, they were plotted at their respective positions on the walk with a ratio equal to the ratio of the sum of the signals.

We thank Professor Alfred Tissières for his interest and support, and we acknowledge the help of Mrs M. Vollenweider and Mrs C. H. Tonka in the task of hand-dissecting salivary glands. This work was supported by a grant from the Swiss National Science Foundation.

Human hepatitis B vaccine from recombinant yeast

William J. McAleer, Eugene B. Buynak, Robert Z. Maigetter, D. Eugene Wampler, William J. Miller & Maurice R. Hilleman*

Division of Virus and Cell Biology Research, Merck Institute for Therapeutic Research, Merck Sharp & Dohme Research Laboratories, West Point, Pennsylvania 19486, USA

The worldwide importance of human hepatitis B virus infection and the toll it takes in chronic liver disease, cirrhosis and hepatocarcinoma, make it imperative that a vaccine be developed for worldwide application[1]. Human hepatitis B vaccines[2–6] are presently prepared using hepatitis B surface antigen (HBsAg) that is purified from the plasma of human carriers of hepatitis B virus infection. The preparation of hepatitis B vaccine from a human source is restricted by the available supply of infected human plasma and by the need to apply stringent processes that purify the antigen and render it free of infectious hepatitis B virus and other possible living agents that might be present in the plasma. Joint efforts between our laboratories and those of Drs W. Rutter and B. Hall led to the preparation of vectors carrying the DNA sequence[7,8] for HBsAg and antigen expression in the yeast *Saccharomyces cerevisiae*[9]. Here we describe the development of hepatitis B vaccine of yeast cell origin. HBsAg of subtype adw was produced in recombinant yeast cell culture, and the purified antigen in alum formulation stimulated production of antibody in mice, grivet monkeys and chimpanzees. Vaccinated chimpanzees were totally protected when challenged intravenously with either homologous or heterologous subtype adr and ayw virus of human serum source. This is the first example of a vaccine produced from recombinant cells which is effective against a human viral infection.

Several alternative approaches to a hepatitis B vaccine are being developed. HBsAg has been expressed by several transformed mammalian cell lines, such as the human hepatoma line, PLC/PRF/5 (refs 10, 11), simian virus 40-infected monkey kidney cells[12] and mouse L cells[13]. These sources are of some concern, however, because the cell lines may be neoplastic. Although HBsAg has been cloned in bacteria[7,14], expression was very weak. Other laboratories[15–19] have described the synthesis of oligopeptides that carry antigenic determinants of HBsAg but their potency in animals is low and much work will need to be done to potentiate antigenicity. Smith and collaborators[20] have described the construction of a recombinant vaccinia virus which expresses HBsAg and have proposed its use as a live attenuated vaccine; its antigenic potency has been demonstrated but whether such a vaccine would be safe and effective in man is still unknown.

Table 1 Antigenic potency in mice of HBsAg purified from yeast and from human plasma

Vaccine source	Antigen dose per injection (μg protein)	Anti-HbsAg response after vaccination No. positive/total	GMT
Human plasma (lot 799-2)	10	9/10	563
	2.5	10/10	2,235
	0.625	4/9	32
	0.156	0/10	4
ED_{50}	0.639		
Yeast (lot 81-4)	40	10/10	5,432
	10	10/10	3,400
	2.5	8/10	673
	0.625	8/10	967
ED_{50}	<0.625		

Groups of 10 5-week-old ICR/Ha mice propagated in our laboratories were given a single 1-ml injection intraperitoneally of serial fourfold dilutions of yeast or human plasma vaccine in alum diluent. The mice were bled individually and tested for serum antibody level 4 weeks later. Human plasma vaccine, lot 799-2, was prepared in these laboratories[2–4]. Yeast-derived vaccine, lot 81-4, was purified as described in Fig. 1 legend and adsorbed to alum. GMT, geometric mean titre, expressed in AUSAB units; ED_{50}, dose required to seroconvert 50% of the mice.

Valenzuela *et al.*[9] originally reported that yeast cells are able not only to express the HBsAg gene but also to assemble the polypeptides into particles that have much the same appearance as particles isolated from human plasma and which are immunogenic in mice. Since then, other laboratories[21,22] have shown that HBsAg produced in yeast is antigenic in rabbits and guinea pigs. With such progress, recombinant yeast has become an attractive alternative to human plasma as a source of antigen for hepatitis B vaccine.

For vaccine preparation, the HBsAg used was of subtype adw and was produced in fermentation cultures of *S. cerevisiae* carrying an expression vector using yeast alcohol dehydrogenase I as a promoter. The yeast strain used in these studies was obtained from G. Ammerer (University of Washington) and is similar to the strain described by Valenzuela *et al.*[9] in which the production of HBsAg in yeast was first reported.

Cells were collected by centrifugation and broken by homogenization with glass beads[23]. HBsAg particles were purified from the clarified extract by immune affinity chromatography using goat antibody to human HBsAg. Electron microscopy (Fig. 1) revealed a homogeneous array of particles free of extraneous morphological entities. The UV absorption pattern was the same as for the plasma antigen, with an $E^{1\%}$ of 45. SDS-polyacrylamide gel electrophoresis (Fig. 2) in reducing conditions revealed a major band at molecular weight 23,000 (23K) corresponding to the non-glycosylated polypeptide which is the major polypeptide of the viral envelope. In this respect it differs from the plasma antigen which has, in addition to the 23K polypeptide, a glycosylated derivative which migrates at 27K. The yeast and plasma antigens differ also in their reactivity in the radioimmunoassay (RIA) (AUSRIA II, Abbott). RIA reactivity of purified yeast-derived HBsAg varied from preparation to preparation in the range 20–50% of the reference human antigen.

Because of this reduced radioimmune reactivity, and because the yeast antigen is not glycosylated, it was important to determine whether the antigen was immunogenic. To test both antigenicity and immunogenicity in animals, purified antigen was formulated into a vaccine by adsorbing on alum adjuvant to contain 40 μg HBsAg protein and 0.5 mg aluminium (hydroxide) per 1 ml dose.

Table 2 Antigenic potency in grivet monkeys of HBsAg purified from yeast and from human plasma

Vaccine source	Antigen dose per injection (μg protein)	Anti-HBsAg response after initial vaccine dose (geometric mean titre) Week 4	Week 8	Week 12	Week 52
Human plasma (lot 86016)	10	36	213	170	127
	2.5	343	6,227	17,348	9.924
	0.625	53	4,642	3,164	5,688
	0.156	15	128	83	358
Yeast (lot 81-4)	40	88	1,078	7,103	11,554
	10	184	877	8,489	4,984
	2.5	225	1,168	6,361	10,868
	0.625	109	925	518	313

A group of four initially seronegative grivet monkeys (*Cercopithecus aethiops*), weighing 3–5 kg, were each given two 1-ml intramuscular (i.m.) doses of yeast or human plasma vaccine 4 weeks apart. Dilutions of antigen were made in alum placebo of the same composition as the vaccine. Animals were bled at biweekly intervals for 1 yr and tested for antibody to HBsAg by using a commercial RIA kit (AUSAB, Abbott). Protein was measured by the method of Lowry[29]. Human plasma lot 86016 was prepared in these laboratories[2–4].

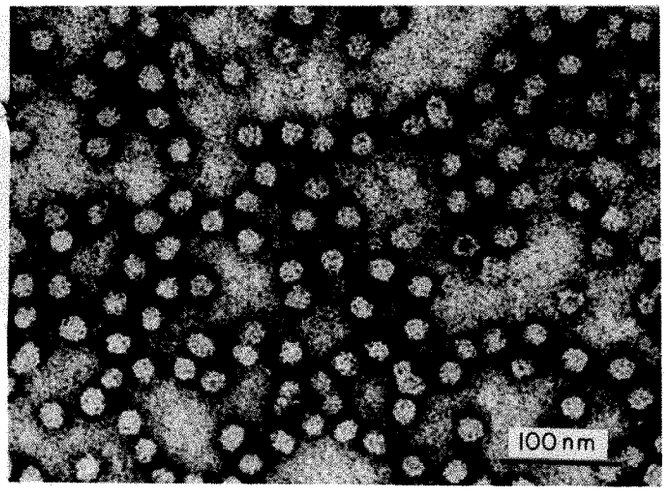

Fig. 1 Electron micrograph of HBsAg particles from recombinant yeast. Cells were grown in a 335-l fermentation vessel, collected by centrifugation, resuspended in an equal volume of 0.01 M sodium phosphate *p*H 7.5, containing 0.01% Triton X-100, and disrupted by rapid stirring with glass beads in a Dyno-Mill (Impandex; see ref. 23). The resulting extract was clarified by centrifugation for 90 min at 10,000*g*. The clarified yeast extract was applied to a column of Sepharose 4B to which had been attached goat antibody to human HBsAg. The column was developed at a flow rate of 2 column vol per h. Extraneous protein was washed away with 5 column vol of buffer A and the HBsAg was eluted with 3 M NH_4SCN. Fractions containing HBsAg were pooled and thiocyanate was removed by dialysis against 0.01 M sodium phosphate *p*H 6.8, containing 0.15 M NaCl. Dialysed antigen was diluted to 40 μg ml^{-1} and visualized by negative staining with 2% phosphotungstic acid.

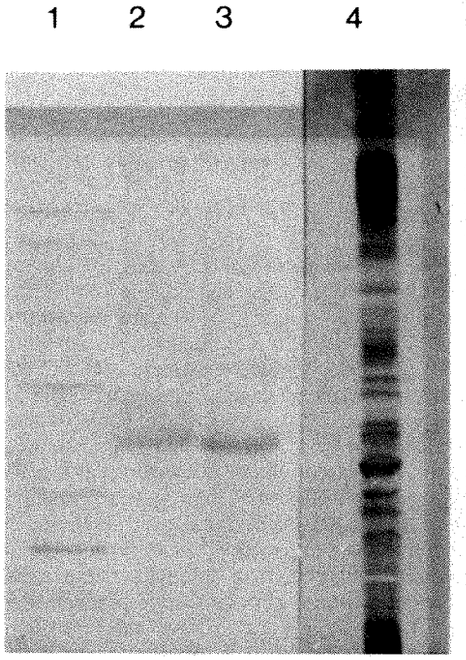

Fig. 2 SDS-polyacrylamide gel electrophoresis of cell culture and yeast-derived HBsAg. All samples were reduced, denatured and electrophoresed as described by Laemmli[30]. After electrophoresis, polypeptides were visualized with Coomassie brilliant blue (lanes 1–3) or with the silver stain procedure described by Morrissey[31] (lane 4). Lane 1, molecular weight standards (3 μg each): phosphorylase *b* (94K), bovine serum albumin (68K), ovalbumin (43K), carbonic anhydrase (30K), soybean trypsin inhibitor (21K) and lysozyme (14.3K). Lane 2, 30 μg of HBsAg from the human hepatoma cell line PLC/PRF/5 (ref. 10), also purified from yeast as described in Fig. 1 legend. Lane 3, 30 μg of HBsAg purified from yeast as described in Fig. 1. Lane 4, 10 μg of clarified yeast extract as described in Fig. 1 legend.

Studies in mice (Table 1) showed the yeast-derived antigen to be at least as antigenic as the antigen purified from human plasma. Grivet monkeys also developed antibody following vaccination with the yeast-derived antigen (Table 2). A single injection of the vaccine at all dose levels resulted in seroconversion of all the animals in both vaccine groups. These results were important as they showed that high antibody titres were maintained for at least a year.

Protective efficacy was tested for by using susceptible chimpanzees. The four chimpanzees that received the recombinant vaccine developed antibody in substantial titre following vaccination (Table 3). Following challenge with infectious human plasma, all four vaccinated animals were protected. By contrast, all four unvaccinated animals developed hepatitis B virus infection with positive antigenaemia, antibody to hepatitis B core antigen (anti-HBcAg), elevation of serum glutamic oxalacetic transaminase (SGOT) and serum glutamic pyruvic transaminase (SGPT), and liver histopathology. It is important to note that the animals were protected against both subtype adr and ayw challenge even though the vaccine is of the adw subtype.

Yeast fermentation technology is well established and we have shown that HBsAg can be isolated from yeast extracts in a highly purified form by a single application of immune affinity chromatography. Vaccine made from this antigen is equally as potent as human plasma-derived vaccine in stimulating antibodies in mice, and is protective in challenge experiments in chimpanzees. Antibodies raised by yeast-derived vaccine persisted for at least a year in monkeys, showing no important deviation from that of the plasma vaccine.

Table 3 Protective efficacy in chimpanzees of HBsAg purified from yeast and from human plasma

Injection	Chimp no.	Before challenge: Anti-HBsAg titre (at 12 weeks)	Before challenge: Antigen subtype	After challenge (week of onset or weeks of duration): HBsAg Onset	HBsAg Duration	Anti-HBcAg Onset	Anti-HBcAg Duration	SGOT elevation Onset	SGOT elevation Duration	SGPT elevation Onset	SGPT elevation Duration	Liver pathology onset
Yeast vaccine (lot 81-4)	110	1,830	adr	–	–	–	–	–	–	–	–	–
	138	540	adr	–	–	–	–	–	–	–	–	–
	103	18,300	ayw	–	–	–	–	–	–	–	–	–
	120	7,200	ayw	–	–	–	–	–	–	–	–	–
Unvaccinated controls	111	<8	adr	10	10	15	9	17	3	17	6	20
	128	<8	adr	8	11	12	12	17	3	16	5	20
	127	<8	ayw	6	14	12	12	13	3	13	7	16
	130	<8	ayw	6	18	10	14	22	1	14	10	24

Eight chimpanzees, each weighing 40–60 kg, were selected for study based on negative findings in tests for HBsAg, anti-HBsAg, anti-HBcAg, elevation in transaminase, liver histopathology and tuberculin reaction. The animals were separated into two groups, four test animals and four controls. Each of the four test animals was given three 40-μg doses of yeast-derived HBsAg vaccine in 1 ml volume i.m. at 4-week intervals. All eight animals were then challenged by intravenous injection of 1,000 chimpanzee infectious doses of subtype adr or ayw virus in 1 ml of human hepatitis B plasma. Antigen and antibody titres were measured by commercial (Abbott) RIA kits (AUSRIA, AUSAB and CORAB for HBsAg, anti-HBsAg and anti-HBcAg, respectively). SGOT and SGPT assays were performed by the Sigma-Frankel (no. 505) and by the UV absorption (Boehringer-Mannheim) procedures, respectively. SGOT titres >40 and SGPT titres >30 were considered elevated. The subtype adr and ayw human plasmas used for challenge were obtained from Drs R. Gerety and E. Tabor of the Office of Biologics, US Food and Drug Administration; they were of measured viral infectiousness for chimpanzees and were subtyped serologically. The animals were bled at weekly intervals during the 36-week period of observation, covering 12 weeks before virus challenge and 24 weeks after. Liver biopsies were taken at 4-week intervals using a Menghini 16T needle. The tissues were fixed in 10% buffered formalin solution and the haematoxylin/eosin-stained sections were prepared by Dr A. Phelps of these laboratories under blind code number. The tests were carried out in animals that were held in isolation in the facilities of Dr William E. Greer at the Gulf South Research Institute, New Iberia, Louisiana. –, All remained negative.

Human HBsAg is composed of a sequence of 226 amino acids of which the a antigen determinant is dominant. Small differences in amino acid sequence may occur at several positions in the polypeptide chain and are responsible for the subtype specificities[24]. In previous studies, chimpanzees that were cross-challenged with heterologous subtypes of hepatitis B virus after recovery from infection or vaccination with human plasma-derived antigens, were solidly protected due to the common group specificity of the dominant a antigen that is present in all HBsAg subtypes[25]. A protective efficacy trial in man of subtype ad vaccine of human plasma origin has shown strong protection against the homologous subtype[26,27] and, most recently, against the heterologous subtype ay[28] in studies carried out on the staffs of renal dialysis centres where subtype ay hepatitis is most common. The positive cross-protection afforded against heterologous subtype ayw virus challenge in chimpanzee immunized with type adw vaccine of yeast origin, indicates that the a antigen remains dominant in the recombinant-produced antigen obtained from human plasma.

We thank Dr C. E. Carty and F. X. Kovach for assistance in fermentation, B. J. Harder, N. Grason and J. Bailey for assistance in antigen purification, Dr B. Wolanski and R. Ziegler for electron microscopy, and H. E. Darmofal, J. T. Deviney, K. I. Guckert, R. R. Roehm and L. W. Stanton for assistance in the animal tests.

Antisera to a synthetic peptide of the *sis* viral oncogene product recognize human platelet-derived growth factor

Henry L. Niman

Department of Molecular Biology, Research Institute of Scripps Clinic, La Jolla, California 92037, USA

It has recently been reported that the sequences of the *sis* oncogene of simian sarcoma virus (SSV) and of human platelet-derived growth factor (PDGF) are very similar[1,2], establishing the most solid link yet between the mitogenic actions of growth factors and the transforming proteins of retroviruses. To investigate molecular mechanisms of transformation I have produced antisera against synthetic peptides corresponding to segments of the protein sequences predicted by the nucleotide sequences of viral oncogenes. Applying this approach to the case of *sis* and PDGF, I report here the results of probing outdated human platelets with an antiserum directed against a synthetic peptide representing residues 139–155 of the predicted sequence of the SSV transforming protein, p28^{sis} (ref. 3). I detected peptides of apparent molecular weights (MWs)

0028–0836/84/020180—04$01.00

© 1984 Macmillan Journals Ltd

30,000 to 31,000 (30–31K) and 16–18K, which correspond to the apparent molecular weights of nonreduced and reduced PDGF[4–8]. In addition, a peptide of MW 21,000 was detected in platelets and a protein of MW 56,000 was detected in SSV-infected marmoset cells.

The *sis* peptide used in this study represents the predicted amino acid residues 139–155 of p28^{sis} (Table 1). If the sequences of PDGF-1 and -2 are colinear with p28^{sis}, these residues would correspond to positions 67–83 and 73–89 of PDGF-1 and -2, respectively. The amino acid sequence of residues 73–80 of PDGF-2 has been determined[1] and all eight amino acids are identical to the first eight amino acids of the synthetic peptide. In addition, the sequence of PDGF corresponding to residues 146–155 of p28^{sis} has been determined[2] and of the nine amino acids which have been identified, all are identical to the corresponding residues in the synthetic peptide. Thus, of the 17 synthesized amino acids which represent the predicted sequence of residues 139–155 of p28^{sis}, 16 have been identified in PDGF and all are identical.

The activities of two sequence-specific antisera are shown in Fig. 1. These antisera were prepared by immunizing mice with synthetic peptides coupled to keyhole limpet haemocyanin (KLH). The anti-*sis* antiserum was made against the peptide shown in Table 1. The anti-*myb* serum was made against a peptide representing residues 2–18 of the predicted sequence of the transforming protein of avian myeloblastosis virus[9]. The anti-*sis* serum reacts with the *sis* synthetic peptide and KLH but not with the *myb* peptide. The anti-*myb* antiserum reacts with the *myb* peptide and KLH but not the *sis* peptide. To test these sera for activity with cognate structures in intact molecules, purified PDGF (given by R. Ross) and an extract of marmoset cells nonproductively infected with SSV (NPV-SSV) were probed with the *sis* and *myb* antisera. Probing the purified PDGF with the anti-*sis* serum readily detected a doublet of MW 16–18K (Fig. 2, lane 1) corresponding to the major reduced forms of PDGF-1 and -2 (refs 4–8). In addition, a major band of 56K was specifically detected by the anti-*sis* serum when probing the cell extract (Fig. 2, lane 2). These activities were blocked by the *sis* conjugate (data not shown). Overexposure of the film also revealed a minor band of 28K (data not shown). The 28K protein corresponds to the predicted size of the SSV-coded transforming protein[3,10] while the 56K protein is the predicted size of the dimer. Although the assay conditions readily reduced the purified PDGF, the major band detected by the anti-*sis* serum in the cell extract was resistant to reduction.

To analyse the size of PDGF in platelets, an extract made from outdated platelets was probed with the anti-*sis* and anti-*myb* antisera. The platelets were treated as described for the first two steps of PDGF purification[4]. This extract was electrophoresed into a polyacrylamide gel and then transferred to nitrocellulose[11]. The extract was then probed with the anti-*sis*

The sequences of p28^{sis}, PDGF-1 and PDGF-2 are from refs 3, 1 and 2, respectively. The presentation of the ref. 2 sequence assumes peptide III originates from PDGF-2, peptide IV originates from PDGF-1, and peptide V originates from both PDGF-1 and PDGF-2. Residues in p28^{sis} that are not identical in all of the sequences determined are underlined. The peptide used in this study is boxed.

* Ref. 1; † ref. 2.

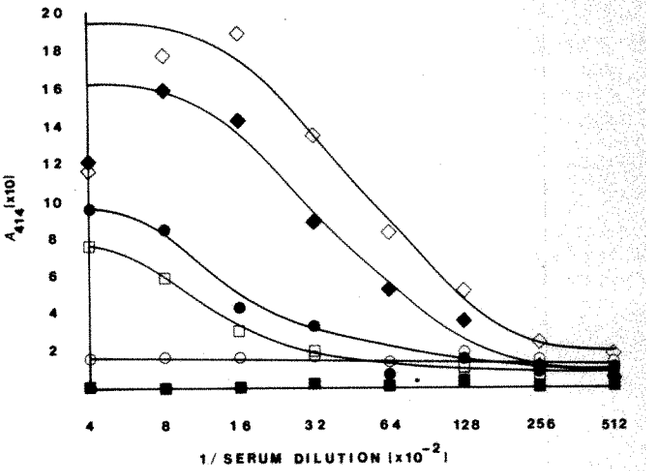

Fig. 1 Immunoreactivities of *sis* and *myb* sequence-specific antisera. The anti-*sis* and anti-*myb* antisera are represented by closed and open symbols, respectively. The antigens are the *sis* peptide (○, ●); the *myb* peptide (□, ■); and KLH (◇, ◆).
Methods: Peptides representing residues 139–155 of the predicted sequence of the SSV transforming protein p28^{sis} (ref. 3) or residues 2–18 of the predicted sequence of the avian myeloblastosis virus[9] were synthesized using solid state methods as described elsewhere[31]. A cysteine was added to the carboxyl end of each sequence for coupling purposes. The amino acid composition of each peptide was determined. For immunization, the peptides were coupled to KLH as described elsewhere[32]. The peptide conjugates were administered at ~50 μg per mouse per injection. On day 0, each conjugate was mixed with an equal volume of Freund's complete adjuvant and injected intraperitoneally (i.p.). On day 19 each conjugate was mixed with a final concentration of 5 mg ml^{-1} alum and injected i.p. For the *sis* conjugate, the final injection, in phosphate-buffered saline (PBS), was given intravenously (i.v.) on day 62 and plasma was taken from blood on day 67 by orbital puncture. For the *myb* conjugate a second alum injection was given on day 41; the final injection was given i.v. on day 143 and the plasma was collected on day 148. To test the specificity of the antisera, 250 ng of unconjugated peptide or 500 ng of KLH were dried onto the bottom of microtitre wells and fixed with methanol as described previously[33]. To prevent nonspecific adsorption, the wells were incubated at 37 °C for 4 h with 3% bovine serum albumin (BSA). 25 μl of serial twofold dilutions of mouse plasma, starting with a 1:400 dilution in tissue culture medium supplemented with 10% fetal calf serum, were incubated with peptide or KLH for 16 h at 25 °C. After washing 10 times with distilled H_2O, 25 μl of rabbit anti-mouse κ (Litton) diluted 1:500 with 1% BSA in PBS were added for 2 h at 37 °C. Then after washing 10 times with distilled H_2O, 25 μl of glucose oxidase-conjugated goat anti-rabbit IgG diluted 1:500 in 1% BSA in PBS were added for 1 h at 37 °C. The amount of glucose oxidase bound was determined by using 50 μl of 100 μg ml^{-1} ABTS dye (Boehringer-Mannheim) in the presence of 1.2% glucose, 10 μg ml^{-1} horseradish peroxidase in 0.1 M phosphate buffer, *p*H 6.0. The optical density at 414 nm was read in a Titertech microscanner.

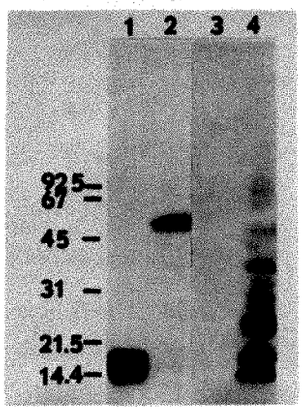

Fig. 2 Immunological detection of purified PDGF and SSV transforming protein on nitrocellulose filters. Approximately 700 ng of purified PDGF with 150 μg carrier BSA (lanes 1, 3) or a lysate of 10^6 SSV-infected cells prepared as described previously[12] (lanes 2, 4) were electrophoresed onto a 7.5–17% polyacrylamide gel and transferred to nitrocellulose as described[11]. After blocking nonspecific binding with 3% BSA and 0.1% Triton X-100 in PBS, 4 ml of mouse anti-*sis* or anti-*myb* sera diluted 1:100 with 3% BSA, 0.1% Triton X-100 were incubated for 16 h at 25 °C. After washing three times with 0.1% Triton X-100 in PBS, 10 ml of rabbit anti-mouse IgG1 (Litton) diluted 1:300 with 3% BSA, 0.1% Triton X-100 in PBS were incubated with the nitrocellulose for 1 h at 37 °C; after washing three times with 0.1% Triton X-100 in PBS, the strips were incubated with 10^7 c.p.m. of ^{125}I-protein A and washed with 0.1% Triton X-100 in PBS. The ^{125}I-labelled lanes were visualized with XRP-1 film (Kodak) and Cronex Hi-plus intensifying screen (Dupont) (−70 °C for 3.5 h). The anti-*sis* serum (lanes 1, 2) was obtained from a mouse immunized using the following protocol. On day 0 the *sis* peptide conjugate was given i.p. at ~50 μg in Freund's complete adjuvant. On days 15 and 31, 50 μg of the conjugate was mixed with 5 mg ml^{-1} alum and injected i.p. The plasma was isolated from blood taken on day 77 by orbital puncture. The anti-*myb* serum (lanes 3, 4) was obtained as described in Fig. 1 legend. The molecular weight standards were lysozyme, soybean trypsin inhibitor, carbonic anhydrase, ovalbumin, BSA and phosphorylase *b*. All of the bonds visualized in lane 4 with the anti-*myb* serum were also seen on longer exposures of lane 2 (probed with the anti-*sis* serum). Only a major band of 56K is seen specifically in lane 2. (Longer exposure revealed a specific 28K protein in lane 2; data not shown.)

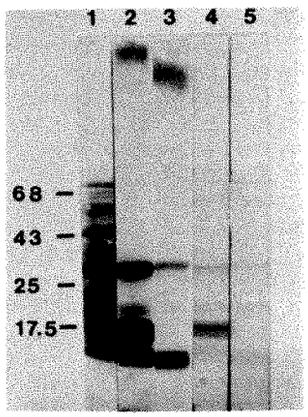

Fig. 3 Immunological detection of nonreduced and reduced PDGF on nitrocellulose filters. Lane 1 is total protein stained with amido-black. Lanes 2 and 3 were developed with ^{125}I; lanes 4 and 5 with dimethoxybenzidine. The platelet extract was probed with the anti-*sis* serum (lanes 2, 4) or the anti-*myb* serum (lanes 3, 5). The molecular weight standards were BSA, ovalbumin, chymotrypsinogen and β-lactoglobulin.

Methods: Using outdated human platelets (16 units; obtained from the San Diego Blood Bank), the first two steps of the PDGF purification were followed[4]. Platelets were collected by centrifugation at 28,000*g* for 20 min at 4 °C, then washed twice by resuspending them in 400 ml of 9-vol 17 mM Tris-HCl *p*H 7.4, 0.15 M NaCl, 0.1% glucose; 1 vol 0.8 g citric acid monohydrate, 2.2 g dextrose (anhydrous), 2.6 g sodium citrate (dihydrate) in 100 ml, and centrifuged at 28,000*g* for 10 min at 4 °C. The washed platelets were resuspended in 16 ml of 0.08 M NaCl, 0.01 M PO_4 *p*H 7.4 and boiled for 10 min. Phenylmethylsulphonyl fluoride and Trasylol were added to a final concentration of 1 mM and 3% respectively. The lysate was mixed with 8 ml CM Sephadex C-50 previously equilibrated with 0.08 M NaCl; 0.01 M PO_4 *p*H 7.4. The platelet pellet was extracted twice with 1 M NaCl for 24 h at 4 °C. After pelleting the insoluble material, the supernatant was dialysed against 0.08 M NaCl, 0.01 M PO_4 *p*H 7.4. PDGF extracted from the pellet was also mixed with 0.5 vol CM Sephadex C-50 equilibrated with 0.08 M NaCl, 0.01 M PO_4 *p*H 7.4. The beads were poured into a 15×1.5 cm column, and washed with 6 column vol of 0.08 M NaCl, 0.01 M PO_4. PDGF was eluted with two column vol of 1 M NaCl. Trasylol was added to a final concentration of 3%, then the eluate was dialysed against 0.08 M NaCl, 0.01 M PO_4 *p*H 7.4. All three extracts were pooled and concentrated with a 10K exclusion filter (Amicon). The extract from ~2.5 units of platelets was adjusted to 0.5% SDS, 5% 2-mercaptoethanol, boiled for 2 min and electrophoresed into a 5–17% polyacrylamide gel. The protein was electrophoretically transferred to nitrocellulose as described[11] and cut into strips. After blocking nonspecific binding with 3% BSA and 0.1% Triton X-100 in PBS, 4 ml of mouse plasma diluted 1:200 were incubated with the nitrocellulose strips. After washing three times with 0.1% Triton X-100 in PBS, the strips were incubated with either 10^7 c.p.m. ^{125}I-labelled protein A or a 1:1,000 dilution of peroxidase-conjugated goat anti-mouse serum (Tago), and washed with 0.1% Triton X-100 in PBS. The ^{125}I-labelled strips were visualized with XRP-1 film (Kodak) and Cronex Hi-plus intensifying screens (Dupont) (−70 °C for 48 h). The peroxidase conjugate was developed with 0.009% H_2O_2, 0.0025% 3,3′-dimethoxybenzidine dihydrochloride (Kodak), 10 mM Tris *p*H 7.4.

and anti-*myb* antisera (Fig. 3): lane 1 is a stain of the total protein bound to nitrocellulose. Although many proteins could be visualized with amido-black staining, PDGF was not present in sufficient quantities to be seen. Figure 3, lanes 2 and 3 show the results of probing with the anti-*sis* and anti-*myb* antisera. Bound antibody was detected with ^{125}I-labelled protein A. The specific bands detected with the anti-*sis* antisera migrated with an apparent MW of ~30K as well as 18–16K. In addition, a minor band of ~21K was detected. Visualization of antibody by benzidine staining[12] of peroxidase-conjugated rabbit anti-mouse IgG (Fig. 3, lanes 4, 5) produced similar results except that the higher molecular weight proteins were resolved as a major band of ~31K and a minor band of 30K. Similarly, the lower bands were resolved as major bands of ~18K and 16K, with protein of a more heterogeneous size migrating between these two bands. In addition, a minor band of ~21K was detected. The specificity of the anti-*sis* antiserum was further tested by preincubation with synthetic peptide conjugates. Incubation of anti-*sis* antiserum with the unrelated *myb* peptide conjugate (Fig. 3, lane 1) did not affect binding to the specific bands seen in Fig. 2, whereas incubation with the *sis* peptide conjugate eliminated detectable binding to all of the specific bands. Only a nonspecific binding (also detected by the anti-*myb* serum, lane 3) which co-migrated with the major protein in the extract was visualized. The mobilities of ~31K and 17K correspond to the unreduced and reduced forms of human PDGF[4–8]. The detection of the ~31 K and 21K bands indicates that the higher molecular weight forms of PDGF in platelets are resistant to reduction.

The data presented immunologically confirm the sequence homology between the SSV oncogene and human PDGF. The factor(s) responsible for the resistance of some of the PDGF and *sis* gene product to reduction is unknown. However, the mitogenic activity of PDGF is associated with the nonreduced forms[6,13,14]. Stimulation of tyrosine-specific kinase activity by PDGF represents the third example of phosphorylation associated with proteins of oncogenes. Members of the *ras* gene family bind GTP and autophosphorylate pp21 (ref. 15). Members of the oncogene family having sequence homology with the carboxyl portion of $pp60^{src}$ phosphorylate IgG *in vitro* and stimulate

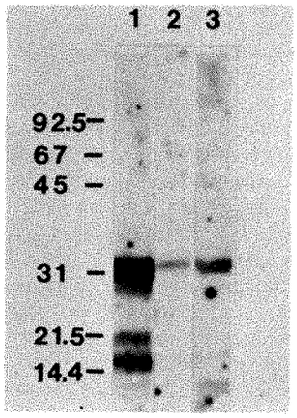

Fig. 4 Immunoreactivity with PDGF is blocked by the synthetic peptide. Platelets were extracted as described in Fig. 3 legend except that Trasylol was added to a final concentration of 1% after elution from the CM Sephadex C-50 column. The extract from ~2.5 units of platelets was adjusted to 0.5% SDS, 5% 2-mercaptoethonal, boiled for 5 min and electrophoresed into a 7.5–17% polyacrylamide gel. Transfer was as described in Fig. 3 legend. The plasma used in lanes 1 and 2 was taken from a mouse immunized as described in Fig. 2 legend except that there was no i.v. injection; instead, the third i.p. injection was in alum and given on day 215 and the plasma was collected on day 223 by orbital puncture. Lane 1, platelet extract probed with anti-*sis* antiserum preincubated with the *myb* conjugate (30 μg for 1 h at 37 °C). Lane 2, anti-*sis* antiserum preincubated with the *sis* conjugate (30 μg for 1 h at 37 °C). Lane 3, extract probed with the anti-*myb* serum. The molecular weight standards were lysozyme, soybean trypsin inhibitor, carbonic anhydrase, ovalbumin, BSA and phosphorylase *b*.

tyrosine phosphorylation in cell extracts[16–23]. Although p28^{sis} does not seem to autophosphorylate or label IgG *in vitro*[10], PDGF stimulation of tyrosine phosphorylation in cell extracts[24–27] suggests that phosphorylation reactions may be involved in numerous pathways important in cell proliferation and transformation.

These pathways can be further characterized using sequence-specific antibodies. This report describes a peptide that readily produces antibodies which recognize the synthetic peptide as well as the cognate structure in the intact molecule. Such peptides can be used for high-frequency isolation of hybridomas secreting useful monoclonal antibodies[12]; these antibodies can be used to map the active site of PDGF. Antibodies which do not block activity can be used to isolate PDGF receptors using immunoaffinity procedures. Monoclonal antibodies will be useful in the characterization of PDGF-related molecules and associated substrates (for example, tumour cells of mesenchymal origin have been shown to express RNA related to v-*sis*[28]). In addition, monoclonal antibodies against sequences unique to each of the PDGF peptides can facilitate their isolation and separation for additional sequencing. Apart from the use of sequence-specific monoclonal antibodies for the characterization of biochemical pathways used in cell proliferation and transformation, selected antibodies should have diagnostic and therapeutic value.

During the preparation of this manuscript, Robbins *et al.* reported[29] the detection of a 56K dimer of the *sis* transforming gene product and the immunological detection of this gene product by an antiserum directed against PDGF. Similarly, Deuel *et al.*[30] showed the reactivity of an anti-PDGF antiserum with a 20K protein in SSV-infected cells.

I thank R. Ross, D. Bowen-Pope and E. Raines for supplying PDGF, R. A. Lerner for discussions, R. A. Houghten for synthesizing and analysing peptides, the San Diego Blood Bank for supplying outdated platelets, R. Naso for supplying SSV-infected marmoset cells, and B. Heilman and D. Schloeder for technical assistance. This work was supported in part by NIH grant CA25803. This is publication no. 3162-MB from the Research Institute of Scripps Clinic.

Primary structure homology between the product of yeast cell division control gene *CDC28* and vertebrate oncogenes

Attila T. Lörincz & Steven I. Reed

Biochemistry and Molecular Biology Section, Department of Biological Sciences, University of California, Santa Barbara, California 93106, USA

In the budding yeast, *Saccharomyces cerevisiae*, division is controlled in response to nutrient limitation[1] and in preparation for conjugation[2]. Cells deprived of an essential nutrient or responding to mating pheromones cease division and become synchronous in the G_1 interval, apparently constrained from completing a critical event. This event has been given the operational designation of 'start'. We have isolated a large number of start mutations which confer on *S. cerevisiae* cells a conditional inability to complete start[3,4] (Fig. 1) presumably because they define genes which must be expressed for the start event to be successfully completed. We have described the isolation on plasmids of one of the start genes, *CDC28*, by genetic complementation[5] and initial characterization of its product[6,7]. We now describe the DNA sequence of the gene *CDC28*.

Comparison of the amino acid sequence encoded by *CDC28* with those of several members of the vertebrate protein kinase family, including a number of viral oncogenes, reveals a significant degree of sequence homology indicating that the latter may have arisen from genes that are essential for cell proliferation and more specifically, for the normal process of cell division control.

The dideoxy method of Sanger *et al.*[8] was used in conjunction with modified M13 phages[9] to sequence a 1.7-kilobase (kb) segment of DNA containing the *CDC28* gene (Fig. 2) and an open reading frame of 298 codons was revealed (Fig. 3). Preliminary nuclease protection experiments[10] indicate that the

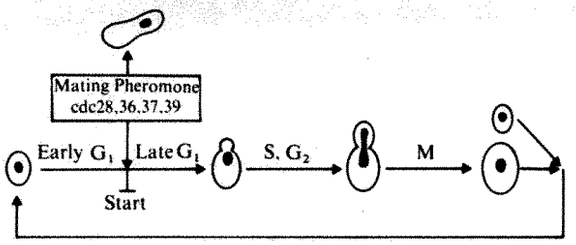

Fig. 1 The yeast cell cycle showing only the relevant details. Execution of start, the controlling event in the cell cycle, depends on both nutritional and pheromonal status. Four genes required for completion of start based on mutational analysis are *CDC28, CDC36, CDC37* and *CDC39* Mutations at these loci produce conditional arrest at start and morphological alterations which cause mutant cells to resemble those responding to mating pheromone. Execution of start signals commitment to completion of the cell division cycle. The cell cycle intervals G_1, S, G_2 and M are shown. The shaded body inside the cell represents the nucleus.

presumptive initiating codon (nucleotide position +1 in Fig. 3) was contained in the *CDC28* mRNA and that the gene contained no introns (data not shown).

The predicted primary structure of the *CDC28* product was subjected to a high resolution computer search which compared it with a large data base of known and predicted protein sequences[11]. As can be seen in Fig. 3, reasonably good homology is detected when the *CDC28* primary structure is compared to those of two distantly related members of the protein kinase family[12]. A 25% identity is obtained when the *CDC28* product is aligned with bovine cyclicAMP-dependent protein kinase[13] and a 22% identity is obtained with v-*mos*, the Moloney murine sarcoma virus oncogene[14]. Furthermore, when subjecting these alignments to the 'jumble test' described by Doolittle[11], the degree of homology was assessed as greater than 6.5 standard

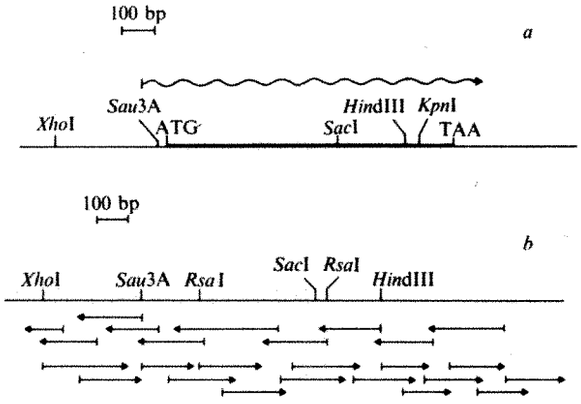

Fig. 2 Sequencing strategy for *CDC28. a*, A region of DNA which had previously been shown to contain the *CDC28* gene[6] with principal restriction sites. The *CDC28* mRNA (wavy line) was oriented[7] and end points determined by S_1 nuclease protection experiments[10]. The open reading frame found by sequence analysis begins approximately 75 nucleotides downstream from the 5′ terminus and ends 90 nucleotides upstream from the 3′ terminus (data not shown). *b*, The directions and limits of the sequencing runs below a map of the region which gives only the restriction sites used as sequencing end points. Part of the gene was sequenced by cloning restriction fragments and *Bal*31 deleted restriction fragments, mobilized using *Eco*RI linkers[7], into M13-derived sequencing vectors[8,9]. However, most of the gene was sequenced by a strategy where M13 clones were subjected to progressive *Bal*31 deletion and sequenced directly. Deletions were initiated at a centrally located unique restriction site and deletion end points were juxtaposed to the sequencing primer site by digestion with a proximal restriction site in the cloning linker segment[9] followed by religation. Deletion end points were aligned by means of restriction mapping so that specific phages could be chosen for sequencing. This approach has the advantages of being extremely rapid and efficient.

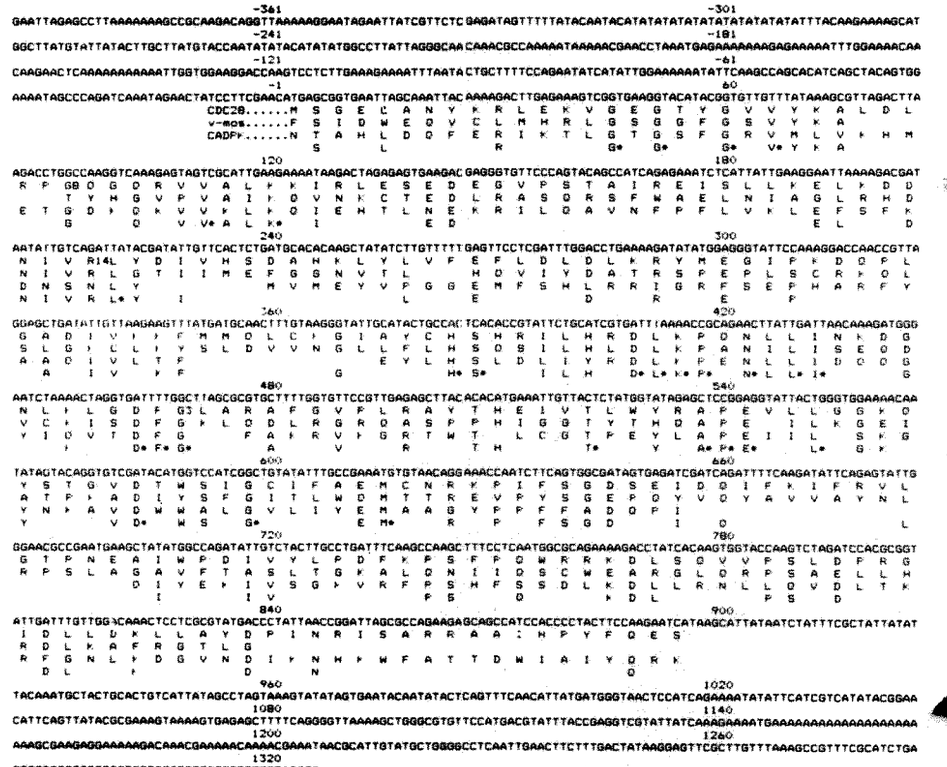

Fig. 3 The nucleotide sequence of the *CDC28* region of the yeast genome and the predicted primary structure of the *CDC28* product. The first nucleotide of the initiating codon (AUG) is given as position +1. Note that the consensus for nucleotides surrounding eukaryotic translational initiation codons is obeyed[18]. The predicted primary structure of the *CDC28* product has been aligned for maximal homology[11] with the predicted primary structure of the oncogene v-*mos* from Moloney murine sarcoma virus[14] (one line down) and the primary structure of cyclicAMP-dependent protein kinase (CADPK) from bovine cardiac muscle[13] (two lines down). This display does not necessarily constitute the maximal homology between the latter two proteins. Where gaps were necessary to obtain optimal alignment, they are indicated by leaving blank spaces (v-*mos* and CADPK sequences) or by inserting the symbol and the number of positions comprising the gap (*CDC28* product sequence). Amino acid homologies observed between the *CDC28* product and either one of the other proteins are indicated (three lines down). Where a homology exists for all three sequences, the amino acid is followed by an asterisk. Homologies observed between v-*mos* and CADPK are not indicated. In addition, both of these sequences have been truncated so that only the region of homology with *CDC28* is displayed. Other noteworthy features of the nucleotide sequence include a stretch of dAT 24 nucleotides long beginning at position −315 and a run of 22 consecutive adenines beginning at position 1146.

deviations above a mean derived by processing a large number of random sequences of identical composition and length via the same algorithm[11]. There is no doubt, then, of the relatedness of the *CDC28* product to these diverse members of the protein kinase family, and good reason to propose that the *CDC28* product is, in fact, a protein kinase itself.

Amino acids common to *CDC28* and either of the two aligned primary structures are indicated in Fig. 3. It is interesting that even though some positions are conserved among all three sequences, many of the relationships hold in one or other of the comparisons but not both. The simplest explanation is that all three sequences are derived from the same ancestral sequence with divergence having occurred early in eukaryotic evolution. Similar matches were obtained with a number of other related viral oncogene product sequences including: Rous sarcoma virus oncogene (*src*; 21% homology), feline sarcoma virus transforming gene (*fes*; 25.5% homology), avian Fujinami sarcoma virus transforming gene (*fps*; 24.5% homology), avian Y73 sarcoma virus transforming gene (*yes*; 25% homology), mouse virus 3611 oncogene (v-*raf*; 24% homology). Most of these have been demonstrated to encode active protein kinases. For a minority, of which v-*mos* is an example, membership in the protein kinase family has been inferred from sequence data, as it has not yet been possible to demonstrate enzymatic activity *in vitro*[15].

Does the sequence homology between the yeast cell cycle gene *CDC28* and viral oncogenes extend to any functional properties? Sequence comparisons between viral oncogenes and their cellular counterparts or proto-oncogenes suggest that the viral forms result from rare transduction events and that their improper expression in the infected host contributes to the transformed state[16] in which normal control of cell division has been lost. An analogous situation in the yeast system is a loss of division control in the fission yeast *Schizosaccharomyces pombe* when carrying the *S. cerevisiae CDC28* gene on a plasmid[17]. Moreover, the *CDC28* gene can complement conditional-lethal *cdc2* mutations in *S. pombe*[17] even though these two organisms are only distantly related and their mode of cell cycle control, at least superficially, dissimilar. Whether the explanation is that the *CDC28* product is unresponsive to normal *S. pombe* control signals or that the plasmid-associated abnormally high gene dosage overwhelms the regulatory capacity of the system, the behaviour of the *S. cerevisiae CDC28* gene in *S. pombe* strikes an interesting parallel with the expression of viral oncogenes in cells of higher eukaryotes and suggests that the gene products in the two yeast species have been highly conserved in the course of evolution. It is probable, then, that underlying division control mechanisms are conserved as well and that, in light of the protein kinase homology, phosphorylation of key target proteins may be involved.

We thank Dr Russell Doolittle for performing the sequence comparisons. This work was funded by NIH grant RO1 GM28005 and NSF grant PCM81-02308 to S.I.R. S.I.R. was supported in part by American Cancer Society Faculty Research Award FRA-248.

Similarity of the *Cin1* repetitive family of *Zea mays* to eukaryotic transposable elements

Nancy S. Shepherd, Zsuzsanna Schwarz-Sommer, Jutta Blumberg vel Spalve, Manju Gupta, Udo Wienand & Heinz Saedler

Max-Planck-Institut für Züchtungsforschung, Egelspfad, D-5000 Köln 30, FRG

It has been suggested that the middle repetitive class of sequences that make up a large proportion of the eukaryotic genome have been amplified and dispersed by DNA transposition[1,2]. Transposition is a phenomenon first postulated by Barbara McClintock on the basis of her genetic analysis of mutants in *Zea mays*[3]. Since then, DNA transposition has been studied genetically in various plant systems[4–6] and is well documented on the molecular level in both prokaryotes and eukaryotes[7]. This has included the isolation of DNA inserts at various loci in several plants[8–15]; however, the prevalence of transposition in plants is not established. We report here DNA nucleotide sequence data which show that some members of the *Cin1* middle repetitive family of maize[16,17] have features characteristic of known transposable elements. One cloned *Cin1* repeat has a 6-base pair (bp) perfect inverted repeat sequence at its ends. The terminal five base pairs (5′ TGTTG ... CAACA 3′) are identical to the termini of *Drosophila copia* transposable elements[18]. Two other *Cin1* alleles are flanked by 5-bp direct repeats. A comparison is made with the long terminal repeat (LTR) of the *copia*–Ty*1*–retrovirus families of moveable genetic elements.

To define the extent of the *Cin1* element we compared the sequence of a given DNA fragment containing the insert with that of the homologous DNA fragment from which the insert is absent, using the NF1 and LC1 recombinant clones isolated from *Z. mays*. NF1 is a 5.7-kilobase (kb) clone from a Northern Flint line of maize which was found to differ from the 5.0-kb LC1 clone of a midwestern maize, line C, by the *Cin1*-001 insert (Fig. 1)[19]. Figure 2*a* shows DNA sequence analysis of the two clones in the region surrounding the *Cin1* insert. The two sequences are quite homologous (90%) except for the *Cin1*-001 insert, the left end of which is shown to be 5′ TGTTGG 3′ while the right end is 5′ CCAACA 3′, thus forming a short, 6-bp perfect inverted repeat at the ends of the element.

Further evidence that the ends of the element are assigned correctly comes from a *Teosinte guerrero* recombinant clone, TG2 (ref. 8). Annual teosintes are thought to be the progenitor of *Z. mays*; however, *T. guerrero* is not one of its closest relatives[20,21]. The TG2 clone is homologous (but not identical) to the LC1 maize clone[8]. There is a strong correlation between the *Teosinte* sequence and that of LC1 (96%) and both show a complete absence of any portion of the sequence which we have assigned to the *Cin1* repeat (Fig. 2*a*).

The final approach used to define the ends of the *Cin1* element was to compare the DNA sequence surrounding the repeat with that found on other recombinant clones containing the *Cin1* repeat. Figure 2*b, c* shows this sequence for two such recombinant clones, LC102 and LC103; the sequences of the *Cin1* elements were clearly similar (87 and 82%, respectively; N.S.S., unpublished data), while the border regions flanking the element were completely different. The ends of the *Cin1* repeat on clone LC102 showed the identical 6-bp inverted repeat as seen for the *Cin1*-001 allelle, but the LC103 clone has one base change, C → T, in this inverted repeat.

From the above analysis we conclude that the *Cin1* element terminates in a 6-bp perfect inverted repeat (5′ TGTTGG ... CCAACA 3′). The presence of short, terminal inverted repeats is a characteristic of most known transposable elements; however, this particular DNA sequence is different from the

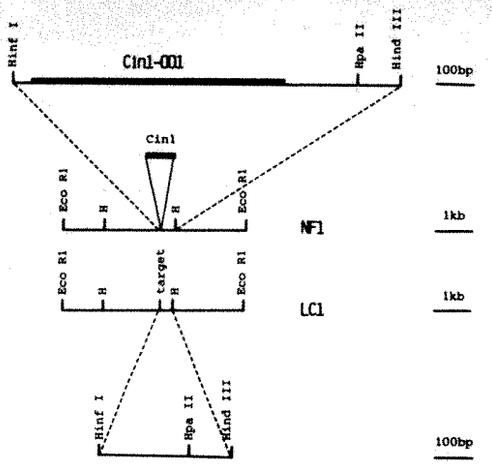

Fig. 1 The *Eco*RI and *Hin*dIII (H) restriction maps of the NF1 and LC1 maize recombinant clones[19]. The two clones were aligned to show their size similarity, except for the *Cin1*-001 sequence (thick bar) which is present on the NF1 clone.

inverted repeat sequence of other known plant DNA inserts[8,12–14]. The terminal 5 base pairs are identical to the termini of the *copia* transposable element of *Drosophila melanogaster*[18], and *Cin1* is the first plant DNA insert examined that contains the TG-CA dinucleotides present at the termini of many eukaryotic transposable elements[7,22].

Another characteristic of transposable elements is the duplication of target site sequence on integration[7]. This criterion is also difficult to analyse for *Cin1* because of the lack of a true target site or an immediate progenitor allele. There is a 5-bp direct repeat flanking the *Cin1* element on both the LC102 and LC103 clones (Fig. 2). The flanking sequence is not identical for the two clones (ATAAT for LC102 and GTTAG for LC103), and their presence is consistent with the notion of the *Cin1* element producing a target site duplication on integration.

Unlike the previously mentioned alleles, the *Cin1*-001 allele on the NF1 clone is not flanked by a 5-bp direct repeat. A direct repeat of 4 bp (CTCG) is present, but displaced from the *Cin1*-001 terminus on one side by two Ts. The significance of this is unknown; however, the presence of an extra base separating a direct repeat from the terminus of an insertion has been observed recently in another system[23].

The fact that the DNA sequence of the *Teosinte* clone shows greater homology with the LC1 sequence than with the NF1 sequence, does not necessarily mean that the LC1 sequence is an older form than that of NF1. *Z. mays* and annual teosintes easily interbreed and are often present in the same field[20,21]. Therefore, it is uncertain whether or not this particular DNA fragment in the *T. guerrero* line has been exchanged with maize during growth of *Teosinte* in the wild. It is just as reasonable to assume that NF1 is the precursor of the others, and that *Cin1* had been excised from the sequence. In this case, the continued presence of the CTCG repeat plus the extra G is reminiscent of recently observed nucleotide alterations of the direct repeat on excision of the *Ds* transposable element of maize[13]. Thus, the DNA sequence of the LC102 and LC103 clones as well as that of the NF1/LC1 set of clones is consistent with the idea of *Cin1* transposition.

It has been mentioned that the TG-CA dinucleotides at the termini of *Cin1* are similar to those of other eukaryotic transposable elements (see above), including several *copia*-like elements of *Drosophila*, the Ty*1* element of yeast, mouse intracisternal A-particle (IAP) genes[24], and the majority of retrovirus proviruses (for reviews see ref. 7). These elements contain a left and a right LTR which form a large direct repeat at the ends of the element and which also end in the dinucleotides TG-CA[7,22,24]. Although the LTR is defined as the terminal direct repeat of a larger element, solo structures which resemble LTRs in size, hybridization or internal sequence organization, have also been found[25–29].

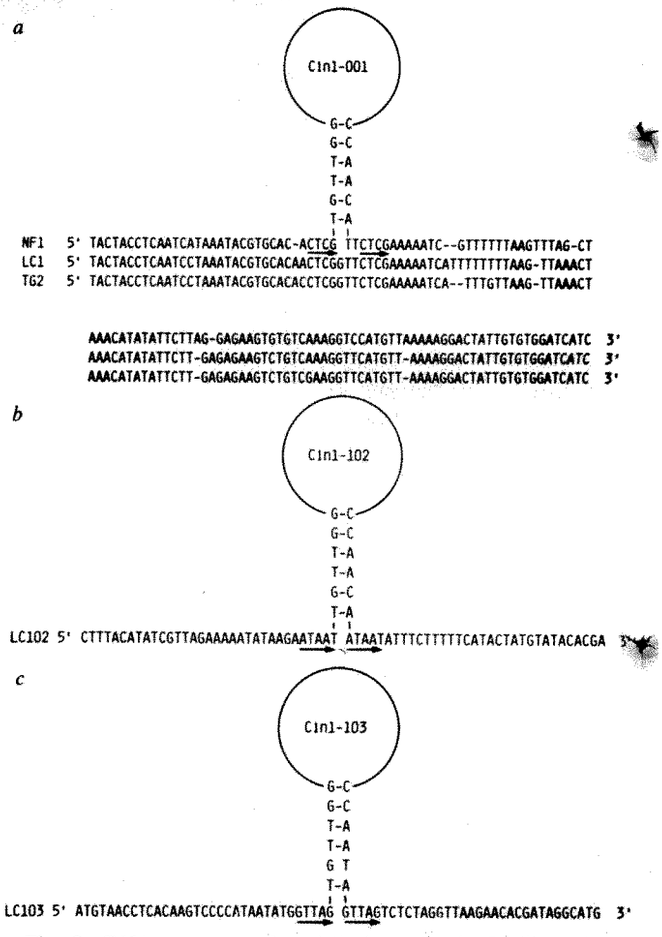

Fig. 2 DNA sequence of regions immediately flanking *Cin1* alleles present on the maize recombinant clones NF1 (*a*), LC102 (*b*), and LC103 (*c*)[16,19]. *Cin1*, as defined in the text, is shown as a stem–loop structure, and direct repeats which flank the element are indicated by arrows. The corresponding homologous DNA sequences of the LC1 and TG2 recombinant clones[8], which do not contain the *Cin1*-001 allele, are also given. The DNA sequences of NF1 (including the *Cin1*-001 sequence of Fig. 3), LC1 and LC1002 were obtained for both DNA strands using standard Maxam and Gilbert sequencing[39] of overlapping restriction fragments. For TG2 and the left side of LC103, only one DNA strand was sequenced, but in both cases the sequence was easily read from a 16 or 8% sequencing gel.

By analogy, the *Cin1* element is similar in size to an LTR, contains the terminal TG-CA dinucleotides, and is found dispersed in the maize genome. The internal structure of the *Cin1*-001 allele is also analogous to that of an LTR[22] (Fig. 3) in that it contains signals for the initiation of RNA transcription[30,31] followed by a poly(A) addition signal[32], and signals thought to be important for the termination of RNA synthesis[33,34]. However, it is unknown whether *Cin1* is transcribed or if it is ever found as the terminal direct repeat of a larger moveable element.

The similarities of *Cin1*-001 to the LTR of retroviruses are striking, but care should be exercised when extending this structural similarity to a mechanistic one. Retroviruses integrate into the animal genome via reverse transcription of the viral RNA genome into DNA[22]. The possibility of reverse transcription in plants has been the subject of many recent articles[35–38] but definitive proof is yet to be provided. Whether or not these sequences are conserved in all *Cin1* alleles is unlikely, for *Cin1* has been shown to be a heterogeneous family[16] and any transposition event may have occurred many years ago, thus allowing mutational drift to occur.

The findings presented here concerning the *Cin1* element of *Z. mays* suggest that it has characteristics typical of a transposable element: it is found in many copies, it has short inverted

Fig. 3 DNA sequence of the *Cin1*-001 allele present on the NF1 recombinant clone. The 6-bp perfect inverted repeat at the ends of the element is marked by a thick arrow. The *Cin1* sequences that are similar to the organization of a retrovirus LTR[22] are as follows. The sequence ACATT (overlined with dashes) is identical to the 'CAT' box[30] found in the LTR of spleen necrosis virus[22]. It is followed 34 bases later by a Goldberg–Hogness 'TATA' box at bases 413–419 (consensus sequence: $TATA^{\hat{A}}_{T}A^{T}_{A}$)[31], a perfect poly(A) addition signal (5′ AATAAA 3′)[32] at 467–472 (overlined), and a CA dinucleotide at position 485 (preferred site for polyadenylation, normally found 10–30 bp downstream from the poly(A) addition signal of eukaryotic genes)[32]. The 15-bp perfect inverted repeat (thin arrows) and the T-rich region (72% T) of the upper strand between bases 516 and 540 (brackets) are both features which may influence termination of RNA transcription[33,34]. The longest open reading frame with an AUG near the 5′ end is located on the lower strand. It begins at position 438 (ATG:*), terminates with the stop codon at position 229 (TAA:*), and possibly encodes a protein of 69 amino acids. A Goldberg–Hogness 'TATA' box is found 85 bp upstream from this open reading frame on the lower strand at bases 572–578. Other 'TATA' boxes and poly(A) addition signals are also present at various, unmarked positions. The total A + T content of *Cin1*-001 is 65%.

repeats at the end which are identical to a known transposable element, and in two cases it was found to be flanked by a 5-bp direct repeat. We conclude, therefore, that DNA transposition has played a part in the dispersion of short repetitive sequences in *Z. mays*.

We thank L. Glahn and R. Berntgen for technical assistance, and Dr Peter Czernilofsky for critical reading of the manuscript.

A large increase in enzyme–substrate affinity by protein engineering

Anthony J. Wilkinson*, Alan R. Fersht*, D. M. Blow†, Paul Carter‡ & Greg Winter‡

* Department of Chemistry and † Department of Physics, Imperial College of Science and Technology, London SW7 2AY, UK
‡ MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

A single point mutation has been engineered in the tyrosyl-tRNA synthetase that improves its affinity (K_M) for its substrate ATP by a factor of 100. In the crystal structure of the tyrosyl tRNA synthetase (of *Bacillus stearothermophilus*), the side-chain hydroxyl of Thr 51 appears to make a weak hydrogen bond with the AMP moiety of the substrate intermediate, tyrosyl adenylate. In the absence of substrate, however, the hydroxyl group should make a strong hydrogen bond with water which would favour dissociation of the enzyme–substrate complex. We have used oligodeoxynucleotide-directed mutagenesis to construct two point mutants at this site: one to remove the hydroxyl group (Thr 51 → Ala 51) and the other, in addition, to distort the local polypeptide backbone (Thr 51 → Pro 51). We report here that both mutants have increased activity (k_{cat}/K_M for ATP) but one mutant (Pro 51) shows a massive 25-fold increase due mainly to a lowered K_M for ATP. This demonstrates dramatically the potential of *in vitro* mutagenesis for improving the affinity of an enzyme for its substrate.

The activities of such bacterial enzymes as β-lactamase[1], 'evolved β-galactosidase'[2,3], amidases[4,5] and ribitol dehydrogenase[6] have been successfully directed towards novel substrates *in vivo* by selecting spontaneous mutations of the enzyme. We are exploring an alternative approach in which we inspect a crystallographic model of the enzyme and attempt to predict the effect of changing a side chain in the active site. We then construct the required mutant by site-directed mutagenesis of the gene, express the enzyme in *Escherichia coli* and measure catalytic activity[7,8].

The tyrosyl-tRNA synthetase (TyrTS) of *B. stearothermophilus* catalyses the aminoacylation of $tRNA^{Tyr}$ in a two-step mechanism in which tyrosine is activated to form enzyme-bound tyrosyl adenylate and then transferred to $tRNA^{Tyr}$. The location of tyrosyl adenylate in the crystal structure indicates that hydrogen bonds are made to the ribose moiety from the side chains of Cys 35, Thr 51 and His 48 (refs 9–11). The Cys 35 interaction has been confirmed by constructing Gly 35 and Ser 35 mutants: these have lowered affinities for ATP resulting either from the complete removal of the hydrogen bond in TyrTS(Gly 35) or from placing the −OH group in TyrTS(Ser 35) slightly too far from the hydrogen bond acceptor on the ATP[7,8]. Interestingly, TyrTS(Ser 35) has a lower affinity for ATP (calculated from k_{cat}/K_M for aminoacylation) than does TyrTS(Gly 35), despite the possibility of a weak hydrogen bond. This probably stems from Ser 35 exchanging a good hydrogen bond with water in the free enzyme for a poor one with ATP on forming the enzyme–substrate complex[8]. As the hydroxyl group of Thr 51 makes a long hydrogen-bonding contact to the ring oxygen (O-1) of the ribose, we predicted that removal of the weak hydrogen bond by constructing an Ala 51 mutant might improve the affinity of the enzyme for ATP.

The Ala 51 mutant was constructed as described previously[7,12] (using a synthetic oligodeoxynucleotide, 5′ AAATGGCGGCCAAGTG 3′) and characterized by dideoxy sequencing[13]. Not only was the Ala 51 lesion confirmed, but also the entire TyrTS gene was sequenced to prove that no other mutations had been introduced inadvertently. For this purpose, a family of five synthetic oligodeoxynucleotide primers staged throughout the TyrTS gene was used (Fig. 1*A*), allowing the complete sequence to be determined on a single salt gradient

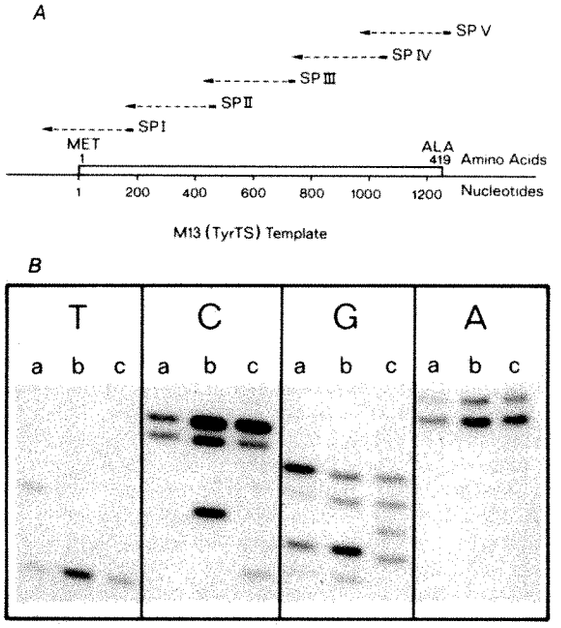

Fig. 1 Sequencing of mutant TyrTS gene. *A*, Oligodeoxynucleotide primers: SPI, 5′ CCCGCCTGCTGGAAGCG 3′; SPII, 5′ TGAACCGACTCTTT 3′; SPIII, 5′ CTCGTACGGCGACGTTT 3′; SPIV, 5′ AAGCGGAACGTCGCCTC 3′; SPV, 5′ TTACTATGCCCAGCGC 3′, complementary to the sequence of the TyrTS gene[15] cloned in M13, were synthesized using phosphotriester chemistry on a polydimethylacrylamide kieselguhr support[16] and purified by ion-exchange HPLC. Templates from the mutants M13TyrTS(Ala 51) and M13TyrTS(Pro 51) were prepared[17] and the genes sequenced by primer extension and the dideoxy chain termination method. As >300 nucleotides from the primer can be read from gradient gels using [α-^{35}S]thio-dATP[14], the complete sequence of each gene may be determined in a single gel. *B*, Sequences of M13TyrTS(Thr 51) (tracks a), M13TyrTS(Ala 51) (tracks b) and M13TyrTS(Pro 51) (tracks c) as determined using the primer SPI. Detection of sequence changes was facilitated by running the T, C, G or A tracks of the three clones in adjacent slots.

gel[14]. By running together the corresponding T, C, G and A tracks of mutant and wild-type clones, sequence changes can be readily detected (Fig. 1*B*).

Mutation of Thr 51 to Ala 51 causes a small change in k_{cat} for both exchange (Table 1) and aminoacylation (Table 2), but decreases K_M for ATP by a factor of two for both reactions. The specificity constant, k_{cat}/K_M, is accordingly increased two-fold, indicating that the enzyme–substrate interaction energy is increased by 0.38 kcal mol^{-1} in the Ala 51 mutant. This is consistent with our prediction that a small increase in enzyme affinity might be engineered by deleting a poor hydrogen bond with the substrate.

Residues 47–61 all have ϕ, ψ angles in the range characteristic of an α-helix (−57°, −48°)[11], but the helix is slightly irregular at the amino-terminus, and the hydrogen bond between Gly 47 (CO) and Thr 51 (NH) may not form. In the homologous *E. coli* enzyme where residue 51 is proline[15], this hydrogen bond could not exist as the nitrogen is locked into the pyrrolidine ring. This must cause a small distortion in the polypeptide backbone around residues 47–51. To examine the effect on the affinity of ATP, we constructed a Pro 51 mutant of the *B. stearothermophilus* enzyme (as above, using the primer 5′ CAAAATCGGGGCCAAGT 3′). The mutation leads to large kinetic changes. In the activation reaction, there is a 15-fold lowering of K_M for ATP and a near doubling of the value of k_{cat}. These combine to give a 25-fold increase in the specificity constant (≡1.9 kcal mol^{-1} of activation energy). In the charging reaction, K_M for ATP is reduced 130-fold for TyrTS(Pro 51), but k_{cat} is also reduced by a factor of 2.6 so that the specificity constant is 50 times higher than that for the wild type (≡2.4 kcal mol^{-1} of activation energy). The detailed stereochemical explanation of this mutation must await further work: for example, it is conceivable that the distortion of the polypeptide backbone introduced by Pro 51 may alter the position of His 48, and increase its interaction with the substrate. However, one factor in the improved affinity must be the removal of the poor hydrogen bond of Thr 51 with ATP.

Table 1 Pyrophosphate exchange activity of tyrosyl-tRNA synthetases

Enzyme	k_{cat}(s^{-1})	K_M (ATP) (mM)	k_{cat}/K_M (s^{-1} M^{-1})
TyrTS	7.6	0.9	8,400
TyrTS(Ala 51)	8.6	0.54	15,900
TyrTS(Pro 51)	12.0	0.058	208,000

Synthetase exchange activity was measured at 25 °C, *p*H 7.8, in 144 mM Tris-HCl, 10 mM $MgCl_2$, 0.1 mM phenylmethane sulphonyl chloride, 10 mM 2-mercaptoethanol, 2 mM pyrophosphate, 50 μM tyrosine, and 100–250 nM enzyme (assayed by active site titration).

Table 2 Aminoacylation activity of tyrosyl-tRNA synthetases

Enzyme	k_{cat} (s^{-1})	K_M (ATP) (mM)	k_{cat}/K_M (s^{-1} M^{-1})
TyrTS	4.7	2.5	1,860
TyrTS(Ala 51)	4.0	1.2	3,200
TyrTS(Pro 51)	1.8	0.019	95,800

The same buffer was used as for Table 1, plus 100 μM ^{14}C-Tyr, 20 μM $tRNA^{Tyr}$ and 25–50 nM enzyme.

Would the mutation to TyrTS(Pro 51) confer a selective advantage on the cell, given its improved K_M with ATP? In addition to any change in other properties of the protein that have as yet not been investigated, such as thermostability, there are clear kinetic disadvantages of TyrTS(Pro 51) *in vivo* because of the high cellular ATP concentration. The intracellular concentration of ATP (2–3 mM) is so high that the wild-type and mutant enzymes are nearly saturated with ATP, thus the reaction rate is controlled by k_{cat} and not k_{cat}/K_M (ref. 8). This confers a slight disadvantage on TyrTS(Ala 51) and a greater disadvantage on TyrTS(Pro 51) in the overall charging reaction (Table 2). However, *in vitro*, TyrTS(Pro 51) is far more active at lower ATP concentration (<2 mM). Also, in the tyrosine activation reaction, TyrTS(Pro 51) is far more active at all concentrations of ATP. (Selective pressure is exerted on the overall aminoacylation reaction rather than on the partial reaction of activation.)

Irrespective of the consequences *in vivo*, the dramatic improvement of K_M for ATP *in vitro* has significant implications for industrial enzymology by demonstrating that it is possible to engineer large improvements in enzyme activity by site-directed mutagenesis.

DON'T TAKE THIS TEST . . .

unless you would like to learn more about publications from the world's largest biological and biomedical information service.

QUESTIONS

1. Where would you look for journal article abstracts in *any* life science field?
   - A. **Biological Abstracts**
   - B. Your local Bookstore
   - C. Library Card Catalogue
2. Which publication provides over 1500 synopses of books in the life sciences each year?
   - A. Reader's Guide to Periodical Literature
   - B. **Biological Abstracts/RRM** (Reports, Reviews, Meetings)
   - C. Scientific American
3. Who publishes **BA** and **BA/RRM**?

ANSWERS

1. **Biological Abstracts (BA),** produced biweekly, provides informative abstracts of current published research from the biological and biomedical journal literature.
2. Rely on **Biological Abstracts/RRM** (also biweekly) to keep up with and select materials for your life science collection. In addition, **BA/RRM** indexes notes, symposia papers, research reports, reviews and meetings.
3. We do. BioSciences Information Service, also known as BIOSIS.

Announcing the new current-awareness journal from Cambridge

New for 1984

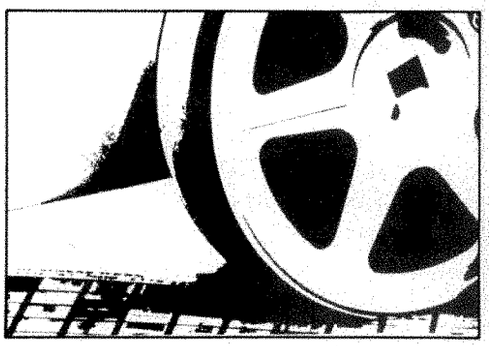
BIO/ESSAYS

Editor-in-chief: **Dr W.J. Whelan** *University of Miami*

Cambridge University Press is pleased to announce this important new monthly which will be launched in July 1984 and published for the ICSU Press, the publishing house of the International Council of Scientific Unions.

BIO/ESSAYS meets the demand for a current-awareness journal devoted to reviews, comment, debate and progress in the frontier areas of molecular, cellular, and developmental biology and their impact on science and society.

Whilst BIO/ESSAYS will concentrate primarily on advances in knowledge from basic research, it will also pay significant attention to actual or potential applications in medicine, industry and agriculture and is of particular interest to those working, or planning a career, in this field. It will debate speculative or controversial aspects of biological research, and disseminate authoritative views and exchanges of views.



Please contact Aileen Askwith, Journals Publicity Controller, for further information.

Leucocyte Typing

Human Leucocyte Differentiation Antigens Detected by Monoclonal Antibodies

Specification - Classification - Nomenclature

Editors: **A. Bernard, L. Boumsell, J. Dausset, C. Milstein, S.F. Schlossman**

1984. 158 figures. 249 tables. Approx. 820 pages.
Cloth DM 124,–; approx. US$48.00
ISBN 3-540-12056-4

Leucocyte Typing comprises the proceedings of the first international collaborative effort to define human leucocyte antigens by monoclonal antibodies. Involving practically all research groups active in the field, this unusually large study was sponsored by INSERM, IUIS and WHO, who will be basing their recommendations with regard to standardization and nomenclature on the workshop results.
The book deals with technical details, surveys the large number of antileucocyte reagents that have been produced, discusses current problems, and draws conclusions concerning the future development of leucocyte typing; as such it is indispensable to the research immunologist. However, it also reviews the progress that has been made and provides a clear guide for the nonspecialist who wishes an up-to-date overview of this new field. The definition of antigens by monoclonal antigens now concerns almost all medical specialties and a study of this kind is essential for present clarity and future progress.

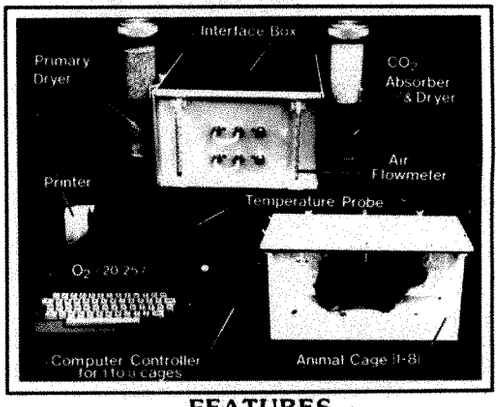
RATS!!!
CARDIAC OUTPUT BY THERMODILUTION

"CARDIOMAX-II-R" is the only computer which can measure cardiac output of rats (also guinea pigs, rabbits, dogs, chickens, horses and humans). For rats, it uses unique Columbus Instruments thermodilution microprobes **1/3 mm in size!** It also measures systolic, diastolic and mean blood pressures and heart rate up to 1000 beats per minute. Stroke volume is also automatically computed.

Why Measure Cardiac Output of Rats?

Development of salt sensitive and salt resistive strains of rats provided inexpensive models for studying hypertension. Dynamics of rat circulatory system is similar to dogs or humans. Studies on rats cost only a fraction of studies using dogs.

Automatic Measurements Without Supervision



All parameters (cardiac output, stroke volume, three blood pressures, blood temperature, heart rate, time of day) can automatically be measured periodically and printed when using **"Cardiomax-II-R"** with Columbus Instruments Automatic Injector and Printer.

O_2-consumption
CO_2-production
Respiration Rate

Simultaneously measured in 1 to 8 animal cages

FEATURES

• One controller for 1 to 8 animal cages • Continuous measurement of O_2, CO_2 and Respiration Rate over a 24 hour period in ml/kg of body weight/hour in STP units. • Printer prints results every four (4) minutes for each of 1 to 8 animals as well as oxygen percent level in each animal cage • System adaptable to small or large animals • Continuous airflow through system with oxygen level measurements at the output and input • High accuracy, >98% of full measuring range e.g. typical error ±30 ml oxygen/kg/hour in 3000 ml oxygen/kg/hour range • User adjustable alarm warns user of possible hypoxia • Reuseable absorbants • Auto reference assures high accuracy, system periodically measures ambient air and corrects itself • Optional RS-232 interface for communication with other computers • Insensitive to temperature variations in the animal cage.

Columbus Instruments also supplies monitors for: Animal Activity, Cardiac Output, Drinking and Feeding, Respiration Rate and Startle Response.

Mathematical pragmatism

Stephen Toulmin

The Nature of Mathematical Knowledge. By Philip Kitcher. *Oxford University Press: 1983. Pp.287. £15, $25.*

IT WAS more than time for a shift of focus in the philosophy of mathematics. With very few exceptions (Henri Poincaré or Hugo Dingler, for example) twentieth-century writers in this field have worked under the shadow of Gottlob Frege; and Frege's classic work, *The Foundations of Arithmetic* (1884), apparently demolished for good the attempt to give mathematics a basis in our empirical experience. In particular, Frege's denunciations of "the genetic fallacy", and of "psychologism", were part of a larger, Platonizing attack on the whole subject, and they have been understood to rule out any hope of introducing historical and mental factors into the analysis of mathematical concepts and propositions.

Since Frege, there have been few truly radical changes in the subject. For all of his originality, Ludwig Wittgenstein's posthumous *Remarks on the Foundations of Mathematics* (1967) never wholly emerged from under Frege's shadow. And although Imre Lakatos's early *Proofs and Refutations* (1963–1964) placed some emphasis on the historical mutability of basic mathematical notions like "validity", "rigour" and "truth", his alliance with Karl Popper led him, later on, to downplay those insights. Instead, he moved toward a more timeless view of the subject matter of mathematics, as part of a distinct "Third World", set apart from all changing physical and mental things.

Although Frege was a contemporary of Ernst Mach, who showed how far the basic concepts of physical theory are the products of human effort over time — so that, as many philosophers of science today would agree, philosophical accounts of scientific concepts need to be *historisch-kritisch dargestellt* — the corresponding insight in the philosophy of mathematics has hitherto made little headway. Nowadays, philosophers rarely focus on the empirical roots of mathematical concepts and procedures, because they have set themselves an oversimplified choice: either, they assume, mathematical truths must be based on empirical experience in the present — the view attributed to John Stuart Mill, which Frege demolished so devastatingly — or, in reaction, they deny to mathematics any empirical basis beyond the self evidence of its axioms and, like Frege himself, treat its claims as transhistorical.

Yet a powerful argument can be presented for thinking that these are not the only options. Must our understanding of the procedures and concepts of mathematics, and even their "meaning", rest solely on observations and experiences that can be pointed to *in the present*? Or do they not depend, equally, on those *past* experiences that led earlier mathematicians to adopt the systems and formalisms they actually did, rather than other systems or formalisms, which were equally consistent and conceivable? This alternative philosophical approach need not, of course, be taken to imply that mathematical statements function as simple reports of past experience. Rather, it asks whether we can fully grasp the intellectual force and scope of mathematical theories and theorems, if we look only at their formal features, in isolation both from the historical contexts in which they took the forms they did, and from the psychological contexts in which children can master them in the present. This richer alternative is one that presses itself on us the more urgently, at a time when philosophers of science have moved so far towards an alliance with historians of scientific thought, and when the developmental studies of L.S. Vygotsky and Jean Piaget have redirected our attention towards the learning of mathematical concepts and procedures.

Philip Kitcher's book, *The Nature of Mathematical Knowledge*, is a pioneer attempt to give a thorough philosophical account of mathematics from this third, and novel, point of view. As is the case with many such enterprises, the book opens up more issues than it can cover to general satisfaction. Still, it has many striking features. It opens with a dozen pages of introduction, which provide a clear and courageous statement of the central programme of the new approach, and this deserves a critical reading by all philosophers interested in the subject, quite aside from the rest of the text. (For instance, the introduction hints at many connections that the author does not pursue further: e.g. at parallels between his view of mathematics and J.J. Gibson's "ecological realism" as a view of sense perception.) Among other good things, subsequent chapters explore helpfully the relations between the "historical–critical" account of change in natural science that has developed in recent years, and the novel picture of historical change in mathematical concepts and procedures that will have to be built up, if the new approach establishes itself as a new research programme for the philosophy of mathematics.

Professor Kitcher's argument falls into three parts. Four chapters clear away philosophical undergrowth, and prepare the ground for the constructive work which occupies the author in Chapters 5 to 9, while a long final chapter is given over to a careful study of the development of "Analysis" as a formal branch of mathematics. (I first wrote "a branch of *pure* mathematics", but struck this out, for Professor Kitcher's approach undermines the traditional contrast between pure and applied mathematics. From his point of view, the only distinctions are ones of degree: based on the comparative distances of different mathematical concepts and theorems from the practical contexts and experiences out of which they initially crystallized.)

Recently, debate within the philosophy of mathematics has become rather specialized and inbred: as a result, those not up in the subject may find the opening part of the book obscure. But such readers are urged to turn to Chapter 5, where much in the constructive exposition of the new position is presented directly and clearly, without reference to current professional controversies. In particular, Professor Kitcher's discussion of the historical character of conceptual change in natural science and mathematics should be read and discussed by many people — working mathematicians and general philosophers, as well as others — who have no particular commitment to one or another of the current rival positions in the philosophy of mathematics.

If this book is in the end somewhat tantalizing, it is for the best of reasons: viz., that the author throws out many more novel ideas and suggestions than he has the space to follow up. Still, at a few points, this gap between promise and achievements affects his argument. To give just one example, his reading of psychology is limited to certain "individualist" traditions: apart from his passing reference to J.J. Gibson, the other main references are (for example) to J.A. Fodor and Noam Chomsky. Hence, for instance, he treats the *warranting* of a belief as a "mental process" in the head of an individual thinker, and ignores the alternative view that treats *warrants* rather as elements within collective procedures of argument that are developed and applied collectively, or "in the public domain".

Minor shortcomings apart, however, this is a valuable and important book. After the careful and thorough criticism of "creationism" in his earlier book, *Abusing Science*, it is a pleasure to see Philip Kitcher making such an original contribution to the philosophy of mathematics, and to general philosophy also. All told, it marks him as having one of the freshest and most versatile minds at work in Anglo-American philosophy today. □

Stephen Toulmin is a member of the Committee on Social Thought at the University of Chicago. His most recent book is The Return to Cosmology: Postmodern Science and the Theology of Nature *(University of California Press, 1983).*

All the way through mammalian skin

Sam Shuster

Mammal Skin.
By V.E. Sokolov.
University of California Press: 1983. Pp.695. £61.50, $72.50.

AFTER many dark years, the academic wilderness of the outer cover has been blown and biomedical scientists are coming out of the warmth of internal prying to the rewarding uncertainties of the cold surface. The spate of cutaneous publishing is part of the celebration and in that sense it may be churlish to ask for sober assessment rather than whoopee.

As might have been expected from a field in which the drive has mostly been pragmatic (disease, fur and pelt production), some topics have been dealt with rather more than others. As might also be expected of an organ whose great complexity is the unique issue of a commune rather than a marriage of other tissues, expertise can easily be maintained in one aspect side by side with the deepest oblivion of neighbourhood experts working on a different topic not a μ or two away. From this it follows that most large skin texts are multi-author jobs and they, and we, all suffer from it. The thrust of this over-long welcome to this singular book must by now be apparent: we have for the first time in the English language a notably unique and personal account of the comparative structure of the mammalian skin.

There is a short general introduction on structure followed by a systematic description covering the entire immense range of mammalian skin, the book ending with a section on adaptive changes. The whole is so exhaustive that you can follow your pet themes right through their evolutionary vicissitudes, and, if you've the stamina left, crack your equally pet theories against reality: you will not travel far without finding some extraordinary and interesting new facts which, at very least, will give you a clutch of new experiments for students. This then is an old-fashioned work of scholarship the like of which is all too rarely seen.

Nonetheless there are some serious defects. The thinking, information and methodology are essentially of the 1960s and earlier, although the original 1974 Russian edition is said to have been updated (in compensation it is salutary to be reminded how well simple methods work — for instance the evidence for the thermo-regulatory function of the fins of certain aquatic mammals); some of the data is thin; and there are some surprising omissions — coat colour and pattern is an opportunity lost. Yet despite the many flaws, including a rudimentary index and indescribably bad photomicrographs, this is an outstanding contribution to the literature. But I do hope that next time round the book gets a thorough revision to bring it into the 1980s; it certainly deserves it. □

Sam Shuster is Professor of Dermatology at the University of Newcastle upon Tyne.

Superficial science

J.E. Inglesfield

Surface Physics, 2nd Edn.
By M. Prutton.
Clarendon: 1983. Pp.138. Hbk £12.50; pbk £6.95.

EVEN before starting to study the chemisorption of carbon monoxide on nickel, a fledgling surface scientist (unless he is a theoretician) will have to be familiar with vacuum techniques, Auger spectroscopy and the theory of low-energy electron diffraction. Professor Prutton's *Surface Physics* is an ideal guide for such a student in his first few terms, introducing him to the techniques used for surface analysis and structure determination, and the main concepts in surface electronic structure, thermal motion of surface atoms and adsorption. Detail is eschewed, but the account is commendably clear and there is an up-to-date list of references.

One of the remarkable features of surface science is the variety of techniques which are routinely used to unravel surface structure. This, quite justifiably, is the topic of the longest chapter in the book, and brief but lucid accounts are given of low-energy electron diffraction (LEED), reflection high-energy electron diffraction (RHEED), field ion microscopy (FIM), ion scattering, photoelectron diffraction and surface-extended X-ray absorption fine structure (SEXAFS). These techniques are based on a whole range of physics, from solving the electronic Schrödinger equation in LEED and SEXAFS to following the classical trajectories of Ar^+ ions with kilovolt energies in ion scattering — the physics of the techniques is briefly but clearly explained. We can expect more techniques (and more confounded acronyms) in the third edition — surely on the way are grazing incidence X-ray diffraction, low-energy atom diffraction and most impressive of all, the scanning tunnelling microscope.

The drawback of a book such as this is that it is inevitably bitty. This makes me less sure about its use by undergraduates. An excellent final-year undergraduate course can certainly be based on surface science, as it provides so many examples of physical principles — particularly quantum mechanics — in action. For example, the electron beam in a LEED experiment will be completely reflected by the surface when its energy coincides with a forbidden energy gap in the bulk band structure, because at such an energy electrons cannot propagate inside the solid. The concept of energy gaps leads to surface states — wavefunctions localized at the surface because their energies lie in a bulk gap below the vacuum zero of energy — of which the dangling bonds on a semiconductor surface provide one example. In the space available Professor Prutton can only touch on topics such as surface states, and the unifying role of surface electronic structure has to be neglected. Undergraduates *will* find the book useful when they want to find out how surface states have been found experimentally.

Anyone beginning a career in a surface science lab will find this little book invaluable. Theoreticians can survive a bit longer than experimentalists without knowing what an ultra-high vacuum is, or what a LEED apparatus looks like, but they cannot get by indefinitely and they too ought to read this book when they begin research. One of the real delights of surface science is that it is still possible to understand most of what's going on, and this book provides an excellent piece of elementary education in the subject. □

J.E. Inglesfield is Head of the Theory and Computational Science Division at the Science and Engineering Research Council's Daresbury Laboratory, Warrington.

Meeting of lizards and ecologists

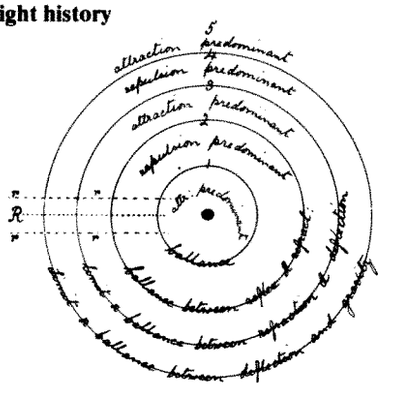
Mark Williamson

Lizard Ecology: Studies of a Model Organism.
Edited by Raymond B. Huey, Eric R. Pianka and Thomas W. Schoener.
Harvard University Press: 1983. Pp.501. $35, £29.75.

FRASER Darling used to advise that the way to start writing is to put a semi-colon in the middle of a blank page. A similar technique has been used in this survey. Most of the chapters started as papers given at a symposium in December 1980, and these have been topped and tailed with introductions to the three main sections and to the book as a whole, and a final overview. The intention is to cover not all but several aspects of lizard ecology, evaluating progress in the past fifteen years.

Much of modern ecological theory stems from the study of birds, particularly from the work of David Lack and Robert MacArthur. The title, and some of the comments, suggests that lizards could be equivalent to birds as model organisms for understanding ecology. They are certainly different, less diverse but far from uniform. The major difference is that lizards are low-energy animals, with the advantages of being easy to observe and capture, hardy in captivity, and many species, particularly in the American west, are abundant. But although the low-energy theme recurs through the papers it is a muted refrain; most authors expound their subject for its own sake, and only by inference compare their subject with the high-energy birds and mammals.

The three sections cover the main aspects of modern ecology. The first quarter of the book is on physiological ecology, an overview and four weakly co-ordinated chapters in different styles. Of the three chapters concerned with energy, one is a long and experimentally sophisticated field study of one species (*Uta stansburiana*), one a short survey of locomotion and metabolism in the laboratory, the third a not very successful attempt to understand distributional limits from the effect of temperature on activity. The other chapter in this section is on the physiological consequences of lizard malaria; this disease causes roughly a 20% decrease in physiological performance, but it may not affect population density. The rest of the book is similar in style, a mixture of detailed studies, broad surveys and loose ends.



The second section, another quarter of the book, is on behavioural ecology and is much concerned with the slippery topic of home range, in *Uta* again, and in relation to sex dimorphism. A short chapter by Regal on adaptive zone and behaviour does address the question of how lizards differ from birds and mammals, the physiological and anatomical limitations of ecological performance, and the diversity of life styles in lizards. Other chapters are less successful.

That leaves half the book for population and community ecology, which is certainly not unreasonable in relation to the excitement of work in those fields in the past couple of decades. The section starts with a sound and helpful overview by Thomas Schoener, and ends with a personal, and more amusing, conclusion by the ornithologist Peter Grant. In between, half the space is taken by *Anolis* in the West Indies. On the Greater Antilles this genus has had a most interesting adaptive radiation, and Ernest Williams extends his previous study on Puerto Rico to encompass Hispaniola and Jamaica, around fifty species in all. In contrast, on the Lesser Antilles there are never more than two species on any one island, and Roughgarden, Heckel and Fuentes consider whether there has been co-evolution of competing populations. Their empirical evidence is reasonably convincing, their mathematical modelling less so. But certainly studies on *Anolis* are important for all ecologists, evolutionists and biogeographers. Chapters by Dunham, by Huey and Pianka, and by Case are also concerned with the measurement of competition, and whether niche overlap is a quantifiable concept. This is an active and controversial field, and the papers here make a useful contribution.

Overall this volume is as patchy as most reports on symposia; the attempts at cohesion are rather flimsy. For instance, the references are grouped at the end, but arranged by chapter and not unified. Lizards have much to tell ecologists, but for the moment those outside the field will have to make their own assessment of the extent to which knowledge of lizard ecology bears on their interests. □

Mark Williamson is Professor of Biology at the University of York.

Light history

William Herschel's diagram of 1780, showing his conception of the force field surrounding a particle of matter. The illustration is taken from *Optics after Newton*, by Geoffrey Cantor, recently published by Manchester University Press. Price is £20.

More or less belief in reproduction

John Habgood

The Biology of Religion.
By V. Reynolds and R.E.S. Tanner.
Longman: 1983. Pp.332. £14.95, $30.

THOSE who enjoy out-of-the-way information will find plenty to entertain them in this fascinating book. Where else could one lay one's hand on comparative figures for obesity among Trappist and Benedictine monks? Or on the Tibetan custom of drinking tea out of a cauldron which has just held a corpse? Or find a discussion of the relationship between wet-nursing, infant mortality and Christian beliefs about sexuality in seventeenth-century France? There are paragraphs here on everything from Islamic divorce to religious massacres. The hugely varied religious beliefs and practices of mankind have been combed for anything which might be thought to have a bearing on the health, survival and reproductive potential of those who profess them. The result is a book which is a delight to read, or to browse in, and which assembles an uncommonly comprehensive range of scientific studies on religious practice across the world.

The bulk of the material is arranged in terms of the human life-cycle, and the religious rituals and moral attitudes associated with each stage in human development in different religious cultures are assessed in terms of their reproductive consequences. There is a somewhat shorter section which tackles specifically the relationship between religion and disease. The results are not always what the protagonists of different religions might wish to believe. There is an uncomfortable suggestion, for instance, that the Flagellants, whose response to the Black Death in the fourteenth century was to go around the countryside flogging themselves to demonstrate their penitence, were actually instrumental in spreading infection.

The layout of the book, with its wide margins and numerous line-drawings, might give the impression that it is designed more for the coffee table than as a serious scientific study. But although the authors hope that general readers will be interested, as surely they will, their main purpose is to expound and test a hypothesis about cultural evolution, using religion as a convenient cultural indicator. It is on this level, therefore, and not as an entertaining compendium, that the work must ultimately be judged.

In the authors' own words, the hypothesis is

that the more unpredictable the total environment is perceived to be, the more people will

want to create and support ideas favouring high levels of reproduction. They will accept the loss of some of their children as inevitable. Conversely, the less unpredictable the environment is perceived to be, the more people will develop ideas favouring low levels of reproduction.

The hypothesis is tested, in the particular case of religion, by classifying different religious strategies as reproductively negative or positive, and then looking for correlation between broad religious traditions and such indicators of environmental stability as energy consumption and gross national product. Not surprisingly, Protestant Christians turn out to be wealthy energy-consumers with inhibited attitudes towards sex, whereas Hindus are just the opposite.

Such a bald summary does not do justice to the considerable subtlety often exercised in the interpretation of religious ideas — the perceptive discussion of celibacy is a case in point — nor to the sensitive exploration of ways in which cultural and physical evolution might in practice interrelate. I welcomed also the frank recognition that there is vastly more to religion than the biologically adaptive dimension on which the authors concentrate. But even within its own terms the main hypothesis seems to me to be thin and unconvincing. I was surprised, for example, to find no mention of the widely canvassed view that Protestant Christianity, far from being a response to an environment perceived as stable, has been a major factor in helping to bring that environment under control. In other words, it is not only the relationships between causes and effects which are uncertain in this immensely complicated field; there is also the question of which is which. □

John Habgood is Archbishop of York. Earlier in his career he was a physiologist and pharmacologist at the University of Cambridge.

Hoyle: comparative excellence

P.N.R. Usherwood

Muscles and their Neural Control.
By Graham Hoyle.
Wiley: 1983. Pp.688.
£61.30, $85.85.

GRAHAM Hoyle's monograph, *Comparative Physiology of the Nervous Control of Muscular Contraction,* was required reading in the late 1950s and early 1960s when comparative neurobiology was still a fledgling undergraduate subject. At that time "according to Hoyle", took on an entirely new meaning. After almost 30 years, the revised version, *Muscles and their Neural Control,* has appeared. It is well written, beautifully illustrated and conveys a most comprehensive, if at times birds-eye view of muscle structure and function across the animal kingdom. It is a remarkable achievement, but hardly a surprising one as the author stands out amongst neurobiologists for the breadth of his research and the length of his bench career. Representing as it does a distillation of his life's work, it commemorates an era which is now sadly slipping away from us.

The book is intended for undergraduates and is at its best when describing those muscle preparations which formed the stepping stones of the author's career — there are numerous references to published and unpublished work of Hoyle and his students — but the style falters when less familiar territory is encountered. His description of muscle fine structure is closely linked to cogent functional correlates and, together with a detailed phylogenetic survey of muscle innervation, this provides a successful approach for those seeking a comparative perspective of muscle.

This account of contemporary knowledge and ideas in nerve-muscle physiology is laced with words of caution from a scientist who clearly resents the oft pejorative interpretation of the term comparative. He is also unhappy about current views on the molecular mechanisms of contraction which have emanated mainly from studies of vertebrate muscle. Past challenges to the cross-bridge hypothesis fashioned from his discovery, or rediscovery, of ultrathin filaments in some muscles have met "a very sceptical, unreceptive audience bent solely upon tracking down the nature of X-bridges". Unfortunately, whilst demanding recognition for our own discoveries we often pay scant regard to other "still small voices" crying in the wilderness of contemporary science. Admittedly authors of undergraduate texts have no choice but to clarify their messages by reducing the surrounding noise of science debate and controversy. Hoyle is no exception in this respect, but I doubt whether dissenters from the vesicle hypothesis for synaptic transmission will appreciate his unquestioning acceptance of this proposal.

In the 1950s it was still possible to pursue a successful career as a comparative physiologist; although it was a struggle to keep abreast of the literature and relevant technological development. It is no longer possible to be a "Jack of all Phyla", as a comparison between Hoyle's original monograph and this new book will clearly show. Despite this, I feel *Muscles and their Neural Control* will be as successful as its predecessor and will, in time, become a classical work. □

P.N.R. Usherwood is Professor and Head of the Department of Zoology, University of Nottingham.

Towards a new phase in physics?

Louis Lyons

Quark Matter Formation and Heavy Ion Collisions.
Edited by M. Jacob and H. Satz.
World Scientific (distributed by Wiley): 1983. Pp.586. £49, $70.

PROTONS and neutrons, the constituents of nuclei, are themselves composed of quarks, bound together by gluons. Richard Feynman is quoted as once saying that the chance of discovering anything fundamental in proton–proton collisions is about the same as that of learning about how balance wheels and mainsprings operate by hurling one watch at another. If that is so, what use can there be in attempting to study the collisions of heavy nuclei with each other?

The hope is that, with a large enough number of protons and neutrons (or equivalently, quarks and gluons), a thermodynamic approach may be possible. Furthermore, it is even conceivable that, at high enough energies, the resulting nuclear matter may become so compressed that new phenomena, not accessible in collisions of just a pair of protons, may occur. In particular, increasing attention has been given to the idea that at high densities the quarks and gluons, rather than being confined inside a single proton or neutron, could wander around freely in a quark–gluon plasma extending over the volume of the two nuclei involved in the collision. Such a phase may have existed during the first millisecond of the Universe.

Several crucial questions in this field immediately come to mind. Does such a phase transition in fact exist, and if so under what conditions? Would we expect the new phase to be attainable in heavy ion collisions (and preferably with accelerators already existing)? What would be the best experimental signatures for deducing whether such a quark–gluon plasma had been created?

Such questions were all addressed at length during a workshop held in Bielefeld in May 1982. These published proceedings give a comprehensive view of both experimental and theoretical facets of the subject at the time. They are clearly required reading for nuclear or elementary particle physicists interested in working in this field (although they would have to update their information from material presented at the subsequent conference at Brookhaven in September 1983). The rest of the scientific community, however, can probably safely wait for a few years until some of the basic questions can be answered by the experiments which are now being planned. □

Louis Lyons is a Lecturer in the Department of Nuclear Physics, University of Oxford.

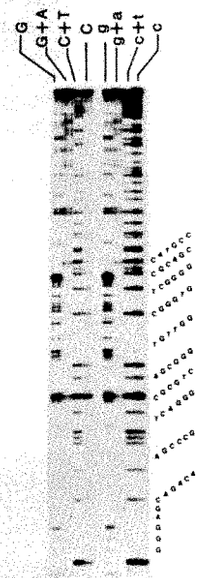
Automatic DNA sequencing

Akiyoshi Wada describes a system that takes the grind out of DNA sequencing

DNA SEQUENCING analysis is of fundamental importance today in pure and applied molecular biology. But the current procedure for analysing DNA sequences is both tedious and time-consuming. In the case of the Maxam-Gilbert scheme, more than thirty steps of microchemical manipulation are involved and these can only be carried out manually by a skilled chemist.

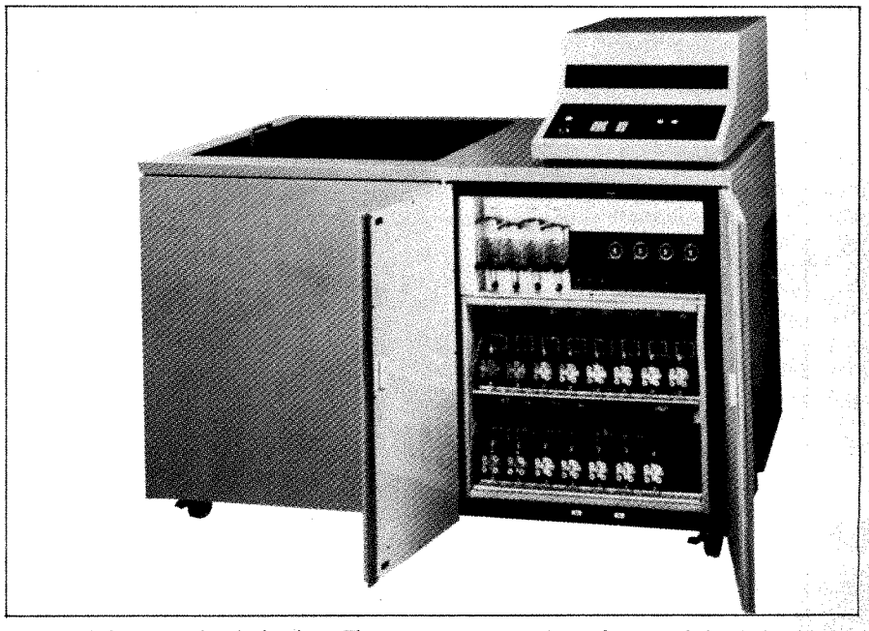
However, even using manual procedures the world-wide rate of analysis may exceed 10^6 bases per year soon, judging by the current rate of additions to the DNA database. But this seemingly high rate of input is far below what is needed to meet the expected demands of sequence analysis in the future. There are many genomes still to be sequenced and even a single human genome has 3×10^9 bases.

An automated DNA sequencer recently developed by Seiko Instruments and Electronics of Tokyo, Japan, should take some of the drudgery out of DNA sequencing and speed up data production. The instrument is a microchemical robot that can carry out the fragmentations of 16 DNA solutions — that is it can test for the four bases (A,G,C and T) in each of four different DNA solutions. It performs the fragmentation in four to five hours, following the Maxam-Gilbert protocol. In addition, it can carry out two sets of operations sequentially so that 10 hours after the start button is pushed, 32 solutions are prepared for electrophoresis. The analysis may be started in the evening as the laboratory closes and then processed material can be collected the next morning.



The fully automatic chemical operations performed by this Seiko robotic instrument include the quantitative addition of reagents, mixing by vortexing, centrifugal separation, draining, vacuum drying, and the heating and cooling of solutions under treatment. The volume of solutions to be handled can be varied from 1 μl to 1 ml. The time schedule and conditions of reaction steps in a series of operations are controlled by a microcomputer command which is input by the operator before the start of the sequencing process. Programmable functions extend this microchemical robot's range of performance to include any of a series of complex chemical reactions of microliter order[1].

The instrument automates just one aspect of the DNA sequencing procedure and will earn a niche in the market by virtue of its labour-saving capacity rather than by any change in the speed or economy of sequencing. The time it takes to determine a sequence is only a little less than that needed to complete a sequence manually, the sequencer runs the same number of solutions as would a skilled technician and it does not save on reagents. But its designers believe that because it can run for 10 hours when the laboratory is effectively closed and because it frees the chemist to carry out other aspects of the sequencing procedure, it will be commercially viable. Tests have shown that the instrument can perform chemical reactions at the same level of efficiency and reliability as a skilled technician. What is more, the automatic sequencer requires no training and works steadily for 24 hours a day without complaining — something which should make it very attractive to the potential buyer!



The machine should be commercially available later this year, although details of the instrument's price and its exact date of launch have not yet been released.

Akiyoshi Wada is professor of biophysics in the Department of Physics, University of Tokyo and the chairman of the project 'DNA extraction, analysis and synthesis'. The DNA sequencer was developed as part of this project under the auspices of the Science and Technology Council of Japan.

1. Wada, A., Yamamoto, M. and Soeda, E. *Rev. Sci. Instr.* (in the press).

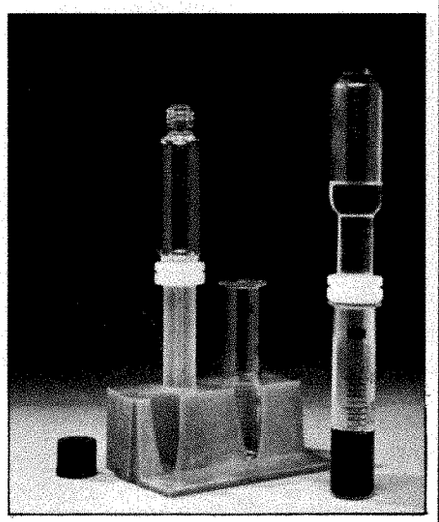
Comparison of sequencing patterns prepared manually (left) and prepared with the sequencer (right).

View of the microchemical robot. The computer system is at the top of the desk and the temperature control dial, stock solutions and pump systems, which are normally under cover, can be seen inside.

General laboratory equipment

● A range of products for use in the DNA laboratory is available from Pharmacia. The products include a centrifugation medium which can be used to separate nucleic acids and proteins. This medium, called CSTFA, allows all types of RNA to be separated by isopycnic centrifugation. Cedium chloride is also available for the preparation of density gradients to purify DNA, and dextran sulphate can be provided to increase the rate of hybridization of nucleic acid molecules. Pharmacia also produces Sephacryl S-1000 which may be used for the removal of low molecular weight material from DNA preparations and in the purification of bacterial plasmid DNA.
Circle No. 100 on Reader Service Card.

● The Schleicher & Schuell Selectasol system is a desk-top chamber for thin layer chromatography (TLC) solvent selection. The Selectasol system is based on the circular development technique. It can be used with TLC ready plates and foils as well as with chromatography papers of between 5 × 10 cm and 20 × 20 cm. Up to 16 different solvent systems can be tested on a standard 20 × 20 cm TLC plate. All the chromatograms develop under the same temperature and relative humidity conditions.
Circle No. 101 on Reader Service Card.



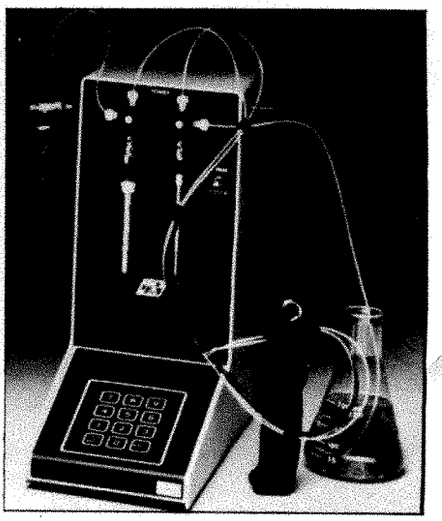
● Two new automatic sample changers are now available from Bioscan. These instruments, the Auto Changer 1000 and 3000, are both compatible with Bioscan's line of radioisotope imaging scanners. Designed to hold from one to three 20-cm thin layer chromatography plates, both instruments provide a system of optical tabs permitting the user to mark up to 60 chromatographic lanes for automated analysis.
Circle No. 102 on Reader Service Card.

● Wheaton Instruments has introduced a new automatic diluter/dispenser which allows samples to be dispensed either manually, semi-automatically or automatically. To accommodate liquids of varying viscosities, the Wheaton diluter/dispenser has an adjustable syringe plunger speed control and an adjustable delay control. Each model is equipped with an interchangeable syringe kit consisting of a sample with a plunger, a reagent syringe with a plunger and a valve assembly. This kit may be removed and autoclaved.
Circle No. 103 on Reader Service Card.

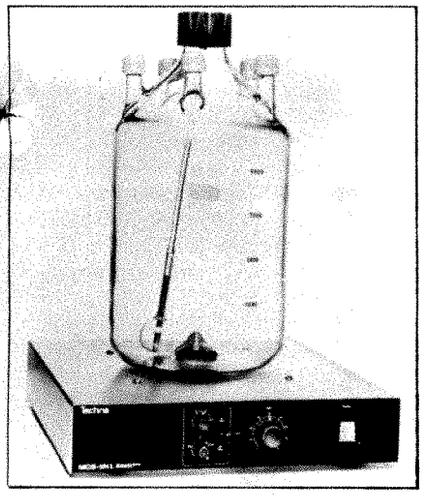
To mark the DNA Winter Symposium taking place in Miami, Florida from 16 to 20 January 1984, this week's selection features products for the molecular biology laboratory. These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

● A new solvent extraction system, designed to replace the separating funnel, is now available from Associated Biolabs. This new Mixxor stirs up the sample and the extraction solvent and then allows them to settle spontaneously into an upper and lower phase. The upper phase can then be decanted without the risk of contaminating it with the lower phase. The Mixxor consists of a glass mixer-reservoir and a glass mixer-separator with a ground glass piston. When fitted together, these can be used in a pumping action. On the 'down' stroke the sample and solvent are forced through a narrow axial channel in the piston into the separator. This produces intimate mixing and leads to very efficient mass transfer. Five strokes of the pumping action produce the same mixing as shaking a separating funnel 40 times. After mixing, the phases are allowed to separate spontaneously. The piston is then adjusted, with the help of a holder-spacer, so that the lower phase is at the very top of the axial channel. The upper phase can then be decanted while the lower phase remains in place. Mixxors are available in four sizes (2, 5, 10 and 20 ml) and are supplied with their own special interlocking racks. These allow an unobscured view of the phase separation.
Circle No. 104 on Reader Service Card.

● An illustrated brochure now available from Beckman Instruments describes the company's system 1 DNA synthesizer. System 1 uses the phosphoramadite chemistry, which means that its cycle times are short and side reactions are minimal. The brochure also describes the system 1+, which includes the DNA synthesizer and a matched HPLC purification system available as a single package of instruments. Both system 1 and system 1+ can be obtained through Beckman's Base-Pak plan.
Circle No. 105 on Reader Service Card.



The Mixxor from Associated Biolabs

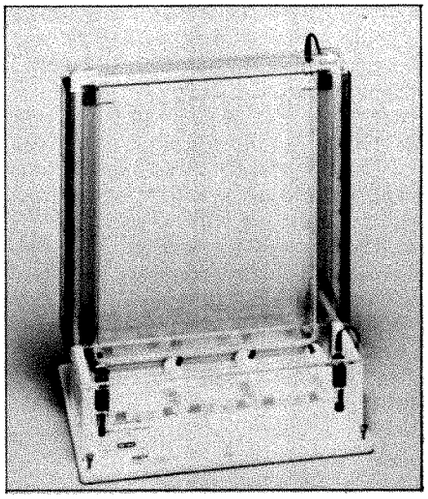


● A new digital syringe diluter/dispenser has been introduced by Dynatech Laboratories. The model 110 is a pipettor/diluter that has a separate dispenser. It has a microprocessor-controlled stepping motor drive and a separate synchronous motor to power the valves. The model 110 can achieve an accuracy of ± 1% at total syringe volume. Volumes to be dispensed are programmed in microlitres into the diluter's memory through a 12-key membrane-type keypad which has a four-digit LED display and eight back-lit legends. Stroke rates can also be programmed. Up to 14 programs can be stored in the diluter's memory and are retained even when power is cut off.
Circle No. 106 on Reader Service Card.

● A line of test tube shakers and rotators has been introduced by Labindustries. The Labquake rotator models provide a constant rotation at 8 r.p.m. Two models are offered which have different capacities and can handle tubes from 10–19 mm diameter to tubes of 27–37 cm diameter, and up to 180 cm long. The Labquake shaker models feature two removable trays. They hold tubes of any diameter up to 162 cm long, and up to 800 g in weight. Speeds may vary from 22 reversals per minute to 70 reversals per minute. Tubes are added and removed while the motor is running. All the shakers and rotators operate on standard 110 V a.c., 50–60 Hz, or 220–240 V a.c., 50–60 Hz. The shakers and rotators are also available in combination models which are supplied with clip bars and interchangeable dual trays.
Circle No. 107 on Reader Service Card.

● A line of sample-handling vials and accessories is available from Kontes. These Microflex vials have a conical cavity which makes it easier to retrieve contents with a syringe needle. Five sizes are available — 0,1, 0.3, 1.0, 2.0, 3.0 and 5.0 ml. Optional closures and finishes are available.
Circle No. 108 on Reader Service Card.

Dynatech Laboratories' diluter/dispenser



One of Techne's microcarrier stirrers

● A range of Techne's microcarrier stirrers is now available from Gallenkamp. These stirrers have been designed to increase cell yields by up to 60%. The stirring system is made from borosilicate glass, siliconized in order to inhibit cell growth on the glass surface. A special 'softstart' prevents turbulence on start-up and the subsequent uniform motion of the stirrer rod aids cell growth. Continuous stirring from 0 to 80 r.p.m. or interval stirring from 6 seconds to 5 minutes 'on' and 2 minutes to 2 hours 'off' is possible. The culture vessels are sealed to prevent contamination. The stirrers can be used with an incubator. Four models are included in the range.
Circle No. 109 on Reader Service Card.

● A series of 5cm × 5mm internal diameter mini-columns has been released by HPLC Technology. The columns are packed with the Techsphere, Spherisorb and Hypersil phases and are guaranteed to produce efficiences of 5,000 theoretical plates per 5 cm column. The 3 μm Techsphere, Spherisorb and Hypersil ranges include the Silica, C 1, C8, C18 (ODS), C18 (ion pair), CN (cyano), NH_2 (amino), phenyl and diol phases).
Circle No. 110 on Reader Service Card.

● The AE100 balance has been added to Mettler's AE line of electronic analytical balances. The AE100 has a weighing range of 0 to 109 g. The weighing chamber is accessible from both sides and from the top. A data output option makes it possible to transfer weights to a printer, calculator or computer.
Circle No. 111 on Reader Service Card.

● A range of regulated power supplies from 500 to 4,000 V has been produced by Fotodyne for electrophoresis, DNA sequencing and electrofocusing. The Fotodyne 4,000 V power supply offers constant power, constant current and constant voltage regulation with automatic crossover capability between all modes.
Circle No. 112 on Reader Service Card.

The model 1800 from Bio-Rad

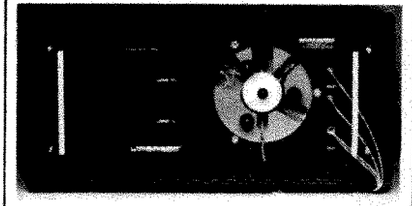
● The new model 1800 DNA sequencing cell from Bio-Rad is designed to reduce the 'smile' effect found when gels are run. The design maintains an even temperature over the gel during electrophoresis. The upper buffer is in contact both with the top of the gel sandwich and with the entire area across one side, so that heat dissipates evenly. Both the upper and lower buffer chambers are incorporated into a single stand that also serves to support the glass sandwich. The sandwich itself is clamped against leakproof seals so that it forms one wall of the extended upper buffer chamber and is in direct contact with the buffer.
Circle No. 113 on Reader Service Card.

● The Drummond Scientific Company has recently added several new dispensing manifold styles to accommodate both 96-well and 24-well microtest plates. For 96-well plates, four-position, eight-position and 12-position manifolds are available. For 24-well microtest plates, 2-position and 6-position manifolds have been added. When attached to the Drummond model 590 digital micro-dispenser, these manifolds can deliver precise aliquots of sample to several positions simultaneously. The manifolds are made of stainless steel.
Circle No. 114 on Reader Service Card.

● A new catalogue detailing BDH calibration kits for gel filtration and gel electrophoresis, SDS polyacrylamide gel electrophoresis and RNA electrophoresis is now available from BDH Chemicals.
Circle No. 115 on Reader Service Card.

● A fluorescence accessory is now available from Beckman Instruments that converts a UV/visible spectrophotometer into a fluorimeter. The accessory can be used with the DU-6 or DU-7 or DU-8B UV/visible spectrophotometer. In using the accessory, the exciting wavelength is first determined by the monochromator setting. The emitted wavelength is then selected with optional filters.
Circle No. 116 on Reader Service Card.

● Tri-Continent Scientific has added an ultra-micropipettor to its line of positive displacement micropipettors. The new pipettor has flexible Teflon tips to facilitate delivery to fragile surfaces, such as those used in electrophoresis, radial immunodiffusion and thin layer chromatography. The pipettor, the Ultra-Micro Absoluter, comes in two models — the 0.5–5μl version and the 2–10 μl version. The capillary tip is reusable.
Circle No. 117 on Reader Service Card.



● Linear Instruments has developed the model 1210 recorder designed for use in liquid or gas chromatography. The model 1210 features a recessed zero adjustment and front-mounted, push button control of power, chart drive and full scale spans. It has an advance/rewind knob for positioning the chart. Chart drive speed is 1 cm min^{-1}, but speeds of 0.25, 0.5, 2 or 4 cm min^{-1} can be achieved through gear changes. The 1210 is a flatbed model which uses 200-mm paper, but it can be wall mounted.
Circle No. 118 on Reader Service Card.

● Heraeus has extended its range of sterile tissue culture vessels by the introduction of Flexiperm. The Flexiperm silicone vessels have an adhesive lower side that sticks to all smooth surfaces to form chambers suitable for culturing cells. The Flexiperm-Slide is used in combination with a standard microscope slide of 75 × 26 mm. The Flexiperm-Disc is intended for use with a Petriperm tissue culture dish, but it may also be placed in a petri dish of polystyrene or glass.
Circle No. 119 on Reader Service Card.

● Wheaton Instruments has introduced the new Step-Pette repetitive syringe dispenser. This delivers pre-set volumes of aliquots from a single draft of fluid. Autoclavable plastic syringes, supplied with the Step-Pette, permit volumes of 10 to 1,000 μl to be pipetted each time the thumb knob is depressed. Once the syringe is primed, 10 to 58 dispensings can be performed depending on the volume of the syringe and adjustment setting selected.

Biologicals

● *Sau* 1 and *Stu* 1 are the latest introductions to Boehringer Mannheim's programme of restriction enzymes. *Sau* 1 recognizes and cleaves the sequence CC/TAGG producing 5′ overlapping ends. It is an isoschizomer of *Cyn* 1 and *Mst* II, and therefore useful in the diagnosis of sickle cell anaemia. *Stu* 1 recognizes and cleaves the sequence AGG/CCT, producing blunt ends. It is an isoschizomer of *Aat* I and *Gdi* I.
Circle No. 121 on Reader Service Card.

● 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside for the visual detection of β galactosidase positive *Escherichia coli* colonies or phage plaques is available from BCL. It comes in pack sizes ranging from 25 mg to 2.5 g. Solutions of X gal at 40 mg ml^{-1} in *N, N*′-dimethylformamide are stable for at least 2 weeks when stored at 4°C.
Circle No. 122 on Reader Service Card.

● New England Nuclear has introduced a new reverse transcriptase system (^{32}P). This should increase yields of double-stranded cDNA (ds-cDNA) from mRNA templates and eliminate unnecessary steps. The system includes all enzymes necessary to make ds-cDNA as a final product. The enzymes, avian myeloblastosis virus (AMV) reverse transcriptase, S_1 nuclease, and DNA polymerase I, are purified and their activities are optimized for the reverse transcriptase system. The system also includes deoxycytidine 5′-triphosphate, (α-^{32}P)- for labelling reaction products, ribonuclease A inhibitor, standardized buffer solutions and distilled water. All components are supplied ready-for-use.
Circle No. 123 on Reader Service Card.

● Reverse transcriptase that has been purified from avian myeloblastosis virus is now available in the UK from Anglian Biotechnology in conjunction with Dr G.E. Houts. Dr Houts has been providing the product for the National Cancer Institute of America. The transcriptase is allegedly free from contaminating RNase activity.

● New England Nuclear has introduced a new nick translation system (^{35}S) that complements its tritium- and ^{35}P-labelled systems. This pre-tested system optimizes preparation of DNA probes labelled with dATPαS, (^{35}S) which are suitable for *in situ* hybridization and Southern transfers. For *in situ* hybridizations, autoradiography exposure times are reduced using the ^{35}S label in place of the tritiated analogue, while the resolution necessary for silver grain counting at the light microscope level is maintained. The system is sufficient for 20 reactions and includes deoxyadenosine 5′ (α-thio)-triphosphate (^{35}S)-, DNA polymerase I, deoxynucleoside triphosphate mixture, DNase 1 and control plasmid DNA.
Circle No. 127 on Reader Service Card.

● Kor Biochemicals has listed details of its 30 growth factors, cell attachment factors, hormones, transport factors and other related biochemicals.
Circle No. 128 on Reader Service Card.

● Promega Biotec is now manufacturing an *in vitro* translation system. The system is composed principally of New Zealand white rabbit reticulocyte lysate preparation. Other components that are added to the lysate include an enzymatic energy generating system, a mixture of tRNAs and haemin. This means that the two translation-qualified amino acid mixtures, one of which lacks leucine and the other of which lacks methionine, and a control sample of brome mosaic virus mRNA must be added to the solution before use. These items are provided in separate vials. The treated rabbit reticulocyte lysate is provided in 200-μl aliquots. This eliminates the need for thawing and refreezing. Promega also manufactures and sells RNasin ribonuclease inhibitor, Packagene single extract lambda DNA packing system, GammaPrep labelled nucleotide synthesis systems and restriction endonucleases, including *Sin*I, *Sca*I, and *Dpn*I, as well as DNA and RNA modifying enzymes.
Circle No. 129 on Reader Service Card.

● Bethesda Research Laboratories (BRL) has introduced Nacs Prepac, a prepacked system for nucleic acid purification. Nacs is BRL's family of ion-exchange resins for use in nucleic acid applications and column chromatography. Filled with Nacs 52, a gravity flow resin, Nacs Prepac can be used in plasmid purification and clone screening, removing unincorporated nucleotides from labelling reactions, and recovering nucleic acids from electrophoresis gels. It is available in two forms — the convertible, for use as a mini-column or pipette tip and the cartridge, for use with a syringe. Both the cartridge and convertible are compatible with a variety of common loading and elution accessories. A Prepac contains enough resin to bind up to 40 μg of A_{260} material.
Circle No. 130 on Reader Service Card.

● Schleicher & Schuell has introduced the S&S Quick-Blot kit. This is a quantitative method for purifying and immobilizing mRNA directly from whole cells or viruses onto nitrocellulose. The new Quick-Blot kit permits selective immobilization of multiple samples of mRNA using dot-blotting techniques in conjunction with the S&S Minifold, a 96-well microsample filtration manifold. The kit can be used to immobilize mRNA from polyribosomes, chromatin, mitochondria, bacteria, yeasts or viruses. Because no baking is required, the mRNA remains biologically active on the nitrocellulose and can be easily translated into polypeptide, reverse-transcribed into cDNA, or released for further manipulation. Each Quick-Blot kit provides sufficient materials to test 120 samples and consists of four basic ingredients: detergents that help rupture the plasma membrane; sodium iodide solutions to promote interaction between mRNA and mRNC and solubilize whole cells at room temperature; NaI-Plus reagent, which furthers the removal of contaminating DNA and protein; and mRNC membrane, an RNA grade nitrocellulose.
Circle No. 131 on Reader Service Card.

● Three new products have been produced by New England BioLabs. The first is a restriction endonuclease, *Hin*P_1I which is derived from *Haemophilus influenzae* P_1. The second is a range of pBR322 *Pst* clockwise site primers for dideoxynucleotide sequencing of DNA. These are specific for the sequence 5′ . .GCTAGAGTAAGTAGTT. .3′. The third new product is a series of dephosphorylated pBR322 cloning vectors which includes *Bam*H1 cleaved and dephosphorylated pBR322, *Hin*d III cleaved and dephosphorylated pBR322, *Eco*R I cleaved and dephosphorylated pBR322 and *Pst* I cleaved and dephosphorylated pBR322.
Circle No. 132 on Reader Service Card.

● Enzo Biochem has added viral specific Patho-Gene kits to the Enzo Bio-Probe system. These kits detect the presence of a virus in fixed cells and tissue preparations. The Patho-Gene kits available contain biotinylated probe DNAs specific for herpes simplex virus I and II, cytomegalovirus, hepatitis B and Epstein Barr virus. The DNA is hybridized and then visualized by a colorimetric enzyme assay for biotin. The Patho-Gene kits are provided with Detek I-hrp, a streptavidin horseradish peroxidase complex.
Circle No. 133 on Reader Service Card.

● Hydroxylapatite, which is used to characterize DNA hybrids and to study reassociation kinetics, is now available from Bio-Rad. It comes in bottles that show the conditions for optimal separation of single and double-stranded DNA on the label.

MOLECULAR BIOLOGY

The Department of Biological Sciences at Dartmouth College seeks candidates for a senior faculty position in the area of molecular biology. The person selected will be expected to pursue an active research program, participate in departmental courses in his or her area of biological interest, and on behalf of the department take the lead in developing an interdepartmental, institution-wide program in molecular genetics. A tenure appointment will be made at the level of Professor, to begin 1 July 1984. We urge all who wish to be considered for the position to submit a current résumé, copies of their most important publications and names of four references.

The search committee will begin reviewing the applicant pool on 15 February 1984. Applications and nominations should be sent to: Secretary, Search Committee, Department of Biological Sciences, Dartmouth College, Hanover, NH 03755. Affirmative Action/Equal Opportunity Employer.

(NW184)A

BIRKBECK COLLEGE (University of London) POSTDOCTORAL RESEARCH ASSISTANT Analysis and Prediction of Protein Structure

Applications are invited for a SERC funded post to work with Dr M Sternberg on the analysis and prediction of protein structure with the aim of obtaining rules to guide protein engineering. This is a theoretical project in the Department of Crystallography which has a colour Evans & Sutherland graphics system and access to the Cray 1-S at ULCC. Experience of computing and macromolecular structure is desirable. The appointment is for three years starting between 1st April and 1st October 1984. Initial salary, according to age and experience, will be between £8,376 and £9,266 pa including London Allowance.

Applications including curriculum vitae and names of two referees should be sent to the Assistant Secretary (Personnel), Birkbeck College, Malet Street, London WC1E 7HX, England. (986)A

UNIVERSITY OF EDINBURGH FACULTY OF MEDICINE

SENIOR LECTURER IN PHYSIOLOGY

Applications are invited from graduates with considerable experience of teaching physiology, a higher degree in medicine or science, experience of supervising post-graduate research assistants, and a capacity to maintain an independent research programme. The successful candidate will be required to contribute to teaching in the department's undergraduate courses and to participate in their co-ordination. The salary is in the range £13,515 to £16,925.

Further particulars are available from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications (8 copies), including names and addresses of three referees, should be lodged not later than 10th February, 1984. Please Quote Reference No. 525. (957)A

UNIVERSITY OF PENNSYLVANIA SCHOOL OF VETERINARY MEDICINE

DEPARTMENT OF PATHOBIOLOGY

PARASITOLOGY FACULTY POSITION

is inviting applications for a tenure probationary faculty position of Assistant or Associate Professor in the Laboratory of Parasitology, with a starting date of 1 July 1984. Applicants are expected to have a DVM and/or a PhD degree. A demonstrated ability and interest in research and teaching in parasitology is essential.

Candidates are requested to submit curriculum vitae and the names of at least three references to: Dr Mark Haskins, Department of Pathobiology, School of Veterinary Medicine, University of Pennsylvania, 3800 Spruce Street, Philadelphia, PA 19104. Application deadline is 1 March, 1984, or thereafter until the position is filled.

The University of Pennsylvania is an Equal Opportunity/Affirmative Action Employer. (NW194)A

Head of Drug Metabolism

Bombay

The Boots Company (India) Ltd., is seeking for its recently established Research Centre in Bombay, a Biochemist who will be in charge of the Drug Metabolism laboratory.

The successful candidate will be involved in the establishment of the unit and will be responsible for designing and conducting drug metabolism and pharmacokinetic studies.

Candidates must have a PhD in Biochemistry with at least five years of postdoctoral/industrial experience in drug metabolism, pharmacokinetics and bioavailability studies. Preference will be given to candidates with experience in:

* instrumental methods of analysis including HPLC
* handling radiolabelled compounds
* dealing with regulatory issues related to all aspects of human studies of drug development and pharmacokinetics.

The position offers an attractive remuneration, support for relocation and good future prospects.

A curriculum vitae along with the names of three referees should be sent to: T. W. Flower, Employment Manager (Technical), The Boots Company PLC, Station Street, Nottingham, NG2 3AA.

The Boots Company PLC

(950)A

Advanced Drug Delivery Research

Our client is recognised as one of the largest and most respected pharmaceutical companies in the world. In line with its policy to lead the field in technological innovation, significant investment has been allocated to set up a new research unit to specialise in advanced drug delivery research. The unit will have approximately 45 staff, and aims to be pre-eminent in its field by the late 1980's.

Opportunities now exist for

SENIOR SCIENTISTS

to help initiate research programmes and to develop multi-disciplinary teams within the unit.
You will combine an impressive academic or industrial background with a proven record of resourceful and, ideally, creative research experience in the fields of cell biology, immunology, virology, bio-chemistry or pharmacy.
The unit is based in Southern England, and the benefits and relocation package is geared to attract the best.
In the first instance write with full CV regarding project number L3102 to:
The Caldwell Partners, 24 Buckingham Gate, London SW1E 6LB.

The Caldwell Partners International
Toronto / Montreal / Calgary / Vancouver / Houston / London

(954)A

CSIRO

Microbiologist

$A24,344 – $A35,806
Division of Plant Industry
Canberra ACT Australia

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Forest Research is a member of the Institute of Biological Resources.

The CSIRO Division of Plant Industry conducts research on problems fundamental to plant biology and agricultural production. As a contribution to improved utilization of renewable energy resources, the Division has a program of research into possible uses of cellulosic crop residues as energy sources for the biological fixation of atmospheric nitrogen.

Duties: To conduct laboratory and field experiments into biological nitrogen fixation associated with microbial populations growing on decomposing wheat stubble, and possibly other crop residues. The research will concentrate in the first instance on definition of ecological aspects and quantification of nitrogen fixation, to be followed by participation in laboratory studies to improve natural systems, and the development of improved practical applications.

Qualifications: Applicants should hold a PhD in relevant aspects of microbiology, or equivalent qualifications, followed by experience in field measurements of biological nitrogen fixation and proven ability to conduct independent research. They should also be prepared to participate actively in collaborative research and in the development of practical applications.

Tenure: Indefinite with Australian Government superannuation benefits available.

Applications: Stating full personal and professional details, names of at least two referees and quoting reference No. A4633, should be directed to:

The Chief,
CSIRO Division of Plant Industry,
GPO Box 1600,
CANBERRA ACT 2601.
AUSTRALIA.
By February 10, 1984.

(W645)A

Division of Cancer Cause and Prevention
National Cancer Institute
National Institutes of Health
Public Health Service
Department of Health and Human Services

ASSOCIATE DIRECTOR FOR CHEMICAL AND PHYSICAL CARCINOGENESIS

The National Cancer Institute (NCI) develops the overall national strategy against cancer, coordinates Federal Government and non-Federal Government cancer programs, and supports international programs of cancer research. The Division of Cancer Cause and Prevention directs the NCI's major research effort related to determining the cause of cancer as well as basic research on possible means of cancer prevention. The Associate Director for Chemical and Physical Carcinogenesis plans, directs, and conducts a basic and applied research program in which agents known or suspected to have carcinogenic and/or tumor promoting activity are evaluated from the standpoint of mechanism of action, metabolism, interactions with biologically important macromolecules, and related areas. The incumbent's responsibilities will also include basic research involving the development of effective agents to prevent or reverse the process of carcinogenesis. The Associate Director will be responsible for the management of both intramural and extramural research programs in chemical and physical carcinogenesis. The chemical and physical carcinogenesis program activities represent a budget of approximately $70 million, eight in-house laboratories, approximately 189 full-time equivalent positions, as well as an extramural component which administers a $49 million grant and contract program.

This is a Civil Service position in the Senior Executive Service (SES) with a salary range from $56,945 to $63,800 per annum. In addition, M.D. candidates may be eligible for a Physician's Comparability Allowance up to $10,000 per year. (Alternately, candidates may be eligible for appointment in the Commissioned Corps of the U.S. Public Health Service.) The individual selected, if not presently in SES, must serve a one year probationary period.

Candidates must meet established mandatory professional/technical and managerial/executive requirements. Candidates will be further evaluated on the extent they exceed the minimum requirements and on additional factors including scientific reputation/peer recognition, training and education and honors and awards. A copy of the requirements may be obtained by contacting Mr. Sherman Hatchett, Personnel Management Branch NCI (301) 496-6864.

Applications (Personal Qualifications Statement SF-171) are to be sent to the above individual at: The National Cancer Institute, Building 31, Room 3A23, Bethesda, Maryland 20205, postmarked no later than February 29, 1984. A current curriculum vitae and bibliography must accompany all applications. Applications from women and/or minority group members are especially solicited.

The National Institutes of Health is an EQUAL OPPORTUNITY EMPLOYER.

(NW188)A

ICRISAT

INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS (ICRISAT) near Hyderabad, India needs the following personnel

PULSE AGRONOMIST

(To be based at ICRISAT Center, Hyderabad, India)

To lead programs of research involving both agronomy and microbiology in relation to N fixation, and to work on chickpea and pigeonpea in a multi-disciplinary program also involving plant breeding, entomology, pathology, and biochemistry. The agronomic work will include studies on varietal response to chemical inputs, response to environmental factors controlling yield such as photoperiod, light, and temperature, and studies on limiting factors including drought, high salt concentration, and high soil pH. The microbiology program will emphasize the development of suitable strains of rhizobia for inoculants and selection criteria for legume host genotypes for breeding programs. Research on legume inoculant production will also be an important activity. *Qualifications:* PhD in Agronomy, Physiology or Microbiology. Significant research experience in crop production and in relation to N uptake or fixation by legumes. Experience in organizing, guiding and coordinating research and in working with a team of research scientists. A minimum of 10 years experience is desirable.

AGRONOMIST — FARMING SYSTEMS RESEARCH PROGRAM

(To be based at ICRISAT Center, Hyderabad, India)

To conduct research both at the research center and at selected on-farm locations. His specific responsibility will be to lead a research team in the development and evaluation of cropping system components of farming systems technologies, working in close collaboration with principal scientists in the farming systems and crop improvement programs. The objectives of ICRISAT's Farming Systems Research Program are to identify more productive farming systems for defined agroclimatic regions. The technologies developed must recognize the resource base of farmers in the rainfed seasonally dry semi-arid tropics, and meet the special needs of small farm holders of limited means. *Qualifications:* PhD in Agronomy (crop production, soil management) or Crop Physiology. Several years of relevant experience and a solid record of scientific achievement with evidence of a systematic approach to the solution of agronomic problems are essential. Should be able to work with scientists from other disciplines to identify and solve crop production problems and with scientists from a wide range of cultures and professional levels in an international team of scientists. Research and/or teaching/extension experience in a developing country is desirable.

CROPPING SYSTEMS AGRONOMIST

(At ICRISAT Sahelian Center, Niamey, Niger)

To work in close coordination with other farming systems research staff in West Africa and at the ICRISAT headquarters. He will work in a team whose work is focused on evolving, evaluating, and testing more productive millet and groundnut based cropping systems for sub-sahelian agroclimatic region. The technologies developed must recognize the resource base of the small farmers and be acceptable to small farm holders of limited means. Research conducted by the agronomist will involve both on-station and on-farm research. For the latter, farmers participate in testing new soil management and cropping systems. *Qualifications:* PhD in Agronomy (crop production, soil management) or Crop Physiology with relevant field experience in crop production. Several years of post-doctoral experience working with scientists of other disciplines on research to identify and solve crop production problems is required; applicant also must be able to work with scientists from a range of cultures and professional levels in an international team of scientists. Agronomic research and/or teaching/extension experience in a developing country and a working knowledge of French desirable.

Salary is at principal staff level, according to qualifications and experience, with attractive fringe benefits.

Send résumé and names of three referees by 15 March 1984 to Director General, ICRISAT Patancheru PO 502 324, A.P., India.

(W658)A

In keeping with our historic interest in reproductive biology and our strong commitment to cell biology, the Worcester Foundation is seeking faculty candidates at all levels with expertise in

Cellular and Molecular Aspects of Reproduction

The Worcester Foundation offers excellent facilities and a highly interdisciplinary and interactive environment for independent researchers. The Foundation's campus is located in the pleasant New England town of Shrewsbury, Massachusetts, 38 miles west of Boston. Interested candidates should send a curriculum vitae with statement of research interests and names of three references to: **David E. Wolf, PH.D., C/O PERSONNEL OFFICE, Worcester Foundation for Experimental Biology, 222 Maple Avenue, Shrewsbury, Massachusetts 01545, USA**

AN EQUAL OPPORTUNITY/AFFIRMATIVE ACTION EMPLOYER M/F/H

WORCESTER FOUNDATION FOR EXPERIMENTAL BIOLOGY

(NW107)A

UNIVERSITY OF SYDNEY LECTURERSHIP/SENIOR LECTURESHIP IN PATHOLOGY

Applications are invited from graduates with registrable medical qualifications and suitable postgraduate training to teach and conduct research in Pathology. Preference will be given to those with higher degrees in a field related to pathology. The Department conducts courses for students in the Faculties of Medicine, Dentistry and Science.

Salary range: Lecturer $A23,394 — $A30,734 pa Senior Lecturer $A31,390 — $36,585 pa Paraclinical loading $A5,848 pa.

Appointments to Lectureships/ Senior Lecturerships are usually probationary for three years and the University reserves the right not to proceed with any appointment for financial or other reasons.

Applications including curriculum vitae, list of publications and names of three referees by 3 February 1984 to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information is available. Enquiries about teaching and research should be directed to Professor D A Cameron, Head of the Department of Pathology.

Equal employment opportunity is University policy.

Further general information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W659)A

HAMPSTEAD HEALTH AUTHORITY

HEAD OF MEDICAL PHYSICS

Salary: £16,090 — £19,117 plus £1,042 London Weighting Allowance

Applications are invited from appropriately qualified and experienced physicists for the above post following the retirement of Mr. H. S. Williams.

The person appointed will be required to advise the District Management Team of developments in Medical Physics.

The department has a staff of 20 and is engaged upon routine clinical services and research and development. The main areas of activity are in radiotherapy physics, nuclear medicine and radiation protection. There is also a substantial commitment to scientific computing and the department has its own electronics work shop.

Informal preliminary interview visits are encouraged and may be arranged by contacting Mr. J. Agnew, Acting Head of Medical Physics on 01-794 0500 ext 3208. Application and job description may be obtained from the Personnel Department, The Royal Free Hospital, Pond Street, Hampstead, NW3 2QG. Telephone 01-794 0500 ext 4286.

Closing date for completed applications 31 January 1984.

(969)A

HAMPSTEAD HEALTH AUTHORITY

SENIOR TOXICOLOGIST

The Rohm and Haas Company, a leading multinational chemical company, has an opening for a Senior Toxicologist at our corporate research headquarters located in Spring House, PA, an attractive suburb of Philadelphia.

The position is for an experienced toxicologist to provide liaison between toxicology and the industrial chemical business of the Rohm and Haas Company worldwide. The individual will be responsible for planning toxicology programs for existing and new industrial chemicals as well as for U.S. premanufacturing notices and EEC premarketing notices. Liaison with Regulatory Agencies in the U.S. and in Europe will be required.

A successful candidate will need a strong background in chemistry and a minimum of 3-5 years industrial toxicology experience, with an M.D., D.V.M. or Ph.D. degree or equivalent in a health-related discipline. The individual must be multilingual, e.g. English, French, and German, and must be willing to travel. Relocation in 2-3 years to Europe may be required.

We offer an excellent salary and benefits program, including relocation assistance, and an environment conducive to professional advancement. Please send a detailed resume, in confidence, to:

Recruiting and Placement #484

PHILADELPHIA, PA. 19105

(NW189)A

An equal opportunity employer M/F.

National Institutes of Health Public Health Service

SENIOR INVESTIGATOR

The Laboratory of Biochemistry, Division of Cancer Biology and Diagnosis, National Cancer Institute, seeks a senior investigator who will conduct a strong independent research program. Applicant's interests should be in the molecular biology/genetics of prokaryotes or lower eukaryotes; they should have an outstanding record of original and independent research accomplishments. The position will be classified as GS 14-15 with a salary range of $42,722 to $65,327 per year depending on qualifications.

Send CV, bibliography, and a short statement of current research interests to Maxine Singer, Chief, Laboratory of Biochemistry, Building 37, Room 4E-28, National Institutes of Health, Bethesda, MD 20205 by February 1, 1984. (Telephone Number (301) 496-5957) U.S. citizenship and an M.D. or Ph.D. or equivalent in experience and training required. NIH is an Equal Opportunity Employer.

(NW217)A

Division of Cancer Cause and Prevention
National Cancer Institute
National Institutes of Health
Public Health Service
Department of Health and Human Services

ASSOCIATE DIRECTOR FOR BIOLOGICAL CARCINOGENESIS

The National Cancer Institute (NCI) develops the overall national strategy against cancer, coordinates Federal Government and non-Federal Government cancer programs, and supports international programs of cancer research. The Division of Cancer Cause and Prevention directs the NCI's major research effort related to determining the cause of cancer as well as basic research on possible means of cancer prevention. The Associate Director for Biological Carcinogenesis plans, directs, and conducts a basic research program in which the role of biological agents, genetic sequences, viral genes, and combinations of viral and cellular genes in carcinogenesis is investigated. This research, which emphasizes molecular biology, includes isolation and analysis of proteins responsible for transformation and identification of the genetic sequences that code the proteins, in addition to the role of RNA- and DNA-containing viruses in certain forms of cancer. The incumbent will be responsible for management of five intramural laboratories and an extramural component which administers a $51 million a year grant and contract program comprising the biological carcinogenesis activities of the DCCP. These activities are supported by a budget of approximately $70 million and approximately 181 full-time equivalent positions.

This is a Civil Service position in the Senior Executive Service (SES) with a salary range from $56,945 to $63,800 per annum. In addition, M.D. candidates may be eligible for a Physicians' Comparability Allowance up to $10,000 per year. (Alternately, candidates may be eligible for appointment in the Commissioned Corps of the U.S. Public Health Service.) The individual selected, if not presently in SES, must serve a one year probationary period.

Candidates must meet established mandatory professional/technical and managerial/executive requirements. Candidates will be further evaluated on the extent they exceed the minimum requirements and on additional factors including scientific reputation/peer recognition, training and education and honors and awards. A copy of the requirements may be obtained by contacting Ms. Patricia Rados, in the Personnel Management Branch, NCI on (301) 496-6864.

Applications (Personal Qualifications Statement SF-171) are to be sent to the above individual at: The National Cancer Institute, Building 31, Room 3A23, Bethesda, Maryland 20205, postmarked no later than February 29, 1984. A current curriculum vitae and bibliography must accompany all applications. Applications from women and/or minority group members are especially solicited.

The National Institutes of Health is an EQUAL OPPORTUNITY EMPLOYER.

(NW191)A

CSIRO

Plant Physiologist

$A24,344 – $A35,806
Division of Forest Research
Mount Gambier SA
Australia

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Forest Research is a member of the Institute of biological Resources.

General: The Division of Forest Research has important programmes in Mount Gambier, South Australia concerned with root growth and functions, nutrient supply to and uptake by trees, nutrient transiocation within trees, and water use by trees. Since these processes are strongly affected by soil water content and the water status of the trees, it is important to initiate work on whole plant water relations, the effects of tissue water status on growth and the interactions between water and nutrition.

The Mount Gambier Station has a total staff of fourteen. The Officer-in-Charge is responsible for integration of the regional programmes and for administration. The appointee will report to him on a day to day basis. General scientific direction comes from the Chief and the Program Leaders in Canberra although most operational aspects of the research will be the responsibility of the appointee. He/she will be in the Soils and Nutrition Program (Leader Dr. T. Talsma) and will be expected to work closely with the Officer-in-Charge at Mt Gambier, Dr. E. K. S. Nambiar. Collaboration with scientists in the ecophysiology program (Leader Dr. S. Linder) will be encouraged.

Duties: The appointee will undertake research into plant water use and the effects of soil-plant water relations on nutrient uptake and movement, and on short and long-term growth patterns.

Qualifications: Applicants should have a PhD degree or equivalent qualifications, supported by proven research activity in a relevant field. Some knowledge and background in environmental physics, as well as plant physiology, is essential.

Tenure: Appointment is for a three year term, with the possibility of a further term not exceeding two years. Australian Government superannuation benefits are available.

Applications: Stating full personal and professional details with the names of at least two referees and quoting reference No. A2872, should be directed to:

The Chief,
CSIRO Division of Forest Research,
PO Box 4008,
QUEEN VICTORIA TERRACE ACT 2600.
AUSTRALIA.
By February 10, 1984.

For further details about the Regional Station contact: Dr E. K. S. Nambiar (087) 25 5555. (NW646)A

DIRECTOR, CENTER FOR ENVIRONMENTAL MANAGEMENT

Tufts University is developing a National Center for Environmental Technology, Health & Policy Research, focusing on issues of hazardous waste. The Director will be responsible for all aspects of the planning and management of the Center. Initial tasks include articulation of the scientific program with Tufts faculty, the sponsoring agency and other public and private sector groups; recruitment, with Tufts faculty, of key scientific personnel; facility planning; and development of the scientific and administrative procedures of the Center. The successful candidate will be an accomplished researcher and administrator, with an advanced degree (e.g., Ph.D., J.D., M.D.) in an appropriate discipline; skill in management of a complex organization; and significant experience in hazardous waste management/research/regulation. The Director will be eligible for professorial appointment in the appropriate Tufts department. Inquiries or resumes (deadline April 1, 1984) should be directed to: Dr. Sol Gittleman, Provost, Chairman, Search Committee, Tufts University, Medford, MA 02155. An Affirmative Action/Equal Opportunity Employer.

(NW205)A

Biotechnology Careers

Challenging career opportunities currently exist in the expanding Biotechnology Section of the Celanese Research Company. The following research positions are available:

BIOCHEMICAL ENGINEER

The successful candidate will join our professional team of dedicated scientists engaged in developing biotechnological processes for the production of a variety of chemicals. The primary responsibility of this R&D position will be to provide effective interfacing between teams of research biologists and chemical engineers towards the successful commercialization of current industrial research programs. In addition to a Ph.D. in Biochemical Engineering or Microbiology applicants must possess a minimum of 2 years in-depth experience in fermentation with an emphasis on bioprocess control and development. Good communication skills and the ability to relate to people on all levels is essential.

MOLECULAR GENETICIST

The primary responsibility of this R&D position will be the application of state-of-the-art genetic and recombinant DNA technology to the development of microorganisms and processes for the production of a variety of chemicals. In addition to a Ph.D. in Bacterial Genetics or Molecular Biology the ideal candidate should have proven expertise in the manipulation of bacteria (preferably gram-negatives) using classic genetic technology in addition to expertise in the manipulation of microorganisms using recombinant DNA technology.

BIOCHEMIST/ PHYSIOLOGIST

This position requires a Ph.D. in Biochemistry or Microbial Physiology, preferably with at least 2 years postdoctoral experience in the area of microbial metabolism and/or the genetic manipulation of microorganisms. The successful candidate will be required to participate in on-going research programs in addition to initiating his/her own programs.

Located at our corporate research center in Summit, New Jersey, these positions offer salary commensurate with credentials and a comprehensive benefits package in addition to a professionally stimulating and rewarding environment.

To be considered for one of these exceptional opportunities please forward a resume with salary history in confidence to **Employee Relations, Dept. SB4, Celanese Research Company, 86 Morris Ave., Summit, New Jersey 07901.**

CELANESE SUMMIT TECHNICAL CENTER

An equal opportunity employer M/F/H/V

SCOTTISH HEALTH SERVICE COMMON SERVICES AGENCY SCOTTISH NATIONAL BLOOD TRANSFUSION SERVICE

DIRECTOR: PROTEIN FRACTIONATION CENTRE

(Re-advertisement)

Salary £22,856 — £26,639

Applications are invited for the above post which is a senior management position within the Scottish National Blood Transfusion Service. The successful applicant, who will be expected to take up the appointment on 1 April 1984, will be responsible to the Management Committee of the Common Services Agency for the processing of all plasma received by the Protein Fractionation Centre and its conversion to therapeutic blood products.

Previous experience in the manufacture of biologicals in the industrial setting and in plasma fractionation would be an advantage.

Whitley Council Terms and Conditions of Service apply. Appropriate information and application forms are available from the Appointments Section, Scottish Health Service, Common Services Agency, Trinity Park House, South Trinity Road, Edinburgh to whom applications should be returned by 2 February 1984. Further particulars and any clarification may be obtained by telephoning 031 664 2317 (ext 259). Please quote reference number U564/N. (947)A

UNIVERSITY OF ALBERTA

DEPARTMENT OF ZOOLOGY

The Department will make one tenurable appointment at the rank of

ASSISTANT PROFESSOR

(minimum $29,720 per annum, 1983-84 scale) on July 1, 1984

This appointment is subject to the availability of funds. Applications are requested from candidates with a PhD degree or equivalent, preferably with postdoctoral experience. The Department is interested in an individual with training and research experience in the field of regulation and/or modelling of freshwater fish populations. The successful candidate will be expected to establish a vigorous research program in this field, in addition to sharing in the teaching program in the areas of vertebrate biology, ecology and fisheries management.

Interested candidates should send a curriculum vitae, a brief statement of research objectives, a list of publications and reprints, and the names and addresses of three referees to: Dr R E Peter, Acting Chairman, Department of Zoology, University of Alberta, Edmonton, Alberta T6G 2E9, Canada. The deadline for receiving applications is March 7, 1984.

The University of Alberta is an equal opportunity employer but, in accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada. (NW202)A

UNIVERSITY OF ALBERTA

DEPARTMENT OF ZOOLOGY

The Department of Zoology, University of Alberta invites applications from individuals who would qualify for support as a Research Scholar at the rank of non-tenured Assistant Professor (1983-84 salary $29,720 to $41,820/annum) or non-tenured Associate Professor (1983-84 salary $37,420 to $53,658). The Department is interested in an individual with training and research experience in the field of vertebrate developmental neurobiology, at the cell or molecular level. Applicants should minimally have a PhD degree or equivalent and postdoctoral experience, and must be highly qualified investigators capable of a vigorous independent biomedical research program. This position will be long-term and will be funded by an external agency such as the Alberta Heritage Foundation for Medical Research but the incumbent will enjoy the privileges of the University academic rank at which the appointment is made. Scholars normally receive extensive support to initiate a research program.

Applicants should forward their curriculum vitae with names of three referees and selected reprints to: Dr R E Peter, Acting Chairman, Department of Zoology, University of Alberta, Edmonton, Alberta T6G 2E9, Canada by March 7, 1984.

The University is an equal opportunity employer, but in accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada. (NW204)A

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF CHILD HEALTH

A POST-DOCTORAL RESEARCH FELLOW

is required for a project investigating the underlying causes of Respiratory Distress in premature infants. The work will include the use of cultured type II alveolar cells from fetal lung as a model system for the development of the capacity for surfactant production. It is intended to study the hormonal regulation and induction of the enzymes of lecithin biosynthesis and of surfactant-associated proteins in these cultures. Experience of protein purification, immunological or tissue culture techniques would be an asset.

The appointment will be for three years starting as soon as possible. The starting salary will be between £7,190 — £8,530 per annum on the Grade IA scale for Research and Analogous Staff.

Further information may be obtained from Dr A D Postle, Department of Child Health, Southampton General Hospital, Southampton (0703) 777222 ext 4336.

Applications (2 copies) giving date of birth, full curriculum vitae, together with the names and addresses of two referees should be sent to Mr A J Small, Staffing Department, The University, Southampton, Hampshire SO9 5NH, as soon as possible. Please quote ref: 1271/R/N. (976)A

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
DEPARTMENT OF PHYSICS
IMAGE ANALYSIS GROUP

APPOINTMENT OF TWO POSTDOCTORAL RESEARCH ASSISTANTS

Two posts for Research Assistants are available, to be filled as soon as possible, for work on the interpretation of images taken using synthetic aperture radar (SAR). The appointments are funded by Ministry of Defence and are tenable each for two years, with possible extension to a third and final year depending on progress.

Both Research Assistants should have doctorate degrees or a similar level of research experience. One post will be primarily theoretical and the other primarily computational/numerical analysis of large image data sets. The theoretical work concerns eg scattering from rough surfaces and image resolution enhancement incorporating the use of external constraints.

Candidates for the theoretical post should have experience in the general area of scattering theory (eg as in optical physics or particle physics), computational image analysis or applications of "fuzzy knowledge". Candidates for the computational post should be competent Fortran computer programmers and might have experience of the use of unitary transforms in physics — ideally, experience of the algorithms and transforms used in image processing. A DEC VAX 11/780 computer system is available in this Department.

The starting salary of one post will be £8,080. The starting salary for the second post is £8,975 pa. London Allowance of £1,186 pa is paid in addition to each salary. Further details can be obtained from Professor R E Burge, Physics Department, Queen Elizabeth College.

Applications with the referees should be sent by 1st February 1984 to Mrs J Staight, Assistant College Secretary, Queen Elizabeth College, Campden Hill Road, Kensington, London W8 7AH. (994)A

UNIVERSITY OF OXFORD
UNIVERSITY LECTURESHIP IN BIOCHEMISTRY AND TUTORIAL FELLOWSHIP AT ST ANNE'S COLLEGE

Applications are invited for a lectureship to be held in the Department of Biochemistry in the field of Enzymology. Stipend according to age on the scale of £7,190 — £15,085. The successful candidate may be offered a stipendiary Tutorial Fellowship at St Anne's College. Details of the post from Professor J Mandelstam, Department of Biochemistry, South Parks Road, Oxford OX1 3QU, to whom completed applications (8 typed copies, two from overseas candidates) and the names of two referees should be sent by 25 February 1984. (973)A

RESEARCH SCIENTIST/PRINCIPAL INVESTIGATOR

Biomedical Application of NMR and Stable Isotopes
Los Alamos National Laboratory

Applications are being accepted for an established research scientist to lead an active biochemistry/NMR program in the Isotope and Nuclear Chemistry Division. This position requires serving as the Principal Investigator for two component programs: "A National Stable Isotope Resource at Los Alamos," supported by the Division of Research Resources of the National Institutes of Health (NIH), and a related Department of Energy (DOE) sponsored program, "Carbon-13 NMR and Metabolism." Direction of the Stable Isotopes Resource will include the supervision of a basic research program to develop new biosynthetic approaches for the synthesis of compounds selectively labeled with stable isotopes of carbon, nitrogen, and oxygen. The DOE program activities include the design and execution of **in vivo** NMR studies of the metabolism of isotopically labeled compounds. The latter program will be carried out in collaboration with the University of New Mexico/Los Alamos Center for Non-Invasive Diagnosis by NMR spectroscopy.

A demonstrated record of accomplishment in the area of high resolution NMR spectroscopy is required. Additional experience in the areas of microbiology, biosynthesis, and analysis of metabolism by NMR techniques is also highly desirable. U.S. citizenship is required. This position provides a unique opportunity for the development of biomedical applications of the stable carbon, nitrogen, and oxygen isotopes produced at Los Alamos.

The Laboratory is operated by the University of California for the Department of Energy. We offer competitive salaries and a full range of employee benefits. Our beautiful mountain location in northern New Mexico has exceptional recreational activities. The school system is excellent and the community provides a casual, relaxed lifestyle.

For further information call Basil I. Swanson, Chairman, Search Committee, Isotope and Structural Chemistry Group, at 505-667-6045.

To apply, please submit resume and letters of recommendation in confidence to:

UNIVERSITY OF LONDON
INSTITUTE OF PSYCHIATRY
DEPARTMENT OF NEUROLOGY
RESEARCH ASSISTANT 1A

Required a postdoctoral research assistant to work on a project involving the electron microscopy of epileptic brain damage. Applicants must have experience in the electron microscopy of the CNS and have a minimum of three years experience of working in a university or hospital in the UK. The project is funded for two years from the Wellcome Trust.

Salary on the Research Staff 1A scale within the range £7,190 — £8,975 pa plus £1,186 pa London Allowance.

For further information contact Dr B Meldrum (Tel: 01-703 5411). For application form send stamped addressed envelope to the Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF (quoting Ref BM/N). Closing date for applications: 2 February 1984. (984)A

THE UNIVERSITY OF CALGARY
Research in Biochemistry

The University Biochemistry Group which comprises members of the Faculties of Medicine and Science offers an interdisciplinary environment for graduate and post-doctoral research in Biochemistry, Molecular Biology and Biotechnology. Highly qualified students with training in biochemistry, chemistry, biology or related disciplines may be admitted to programs leading to the MSc and PhD degrees.

Research/teaching assistantships ($8,775.00 to $11,700.00/yr) are available from the University. Studentships ($11,400.00/yr plus $2,500.00 research allowance) and post-doctoral fellowships ($20,760.00/yr plus $5,000.00 research allowance) are available from the Alberta Heritage Foundation for Medical Research and may be applied for via The University of Calgary. Interested individuals should send a curriculum vitae which includes courses taken and grades obtained and a statement of research interests to:

Dr Barry Lesser, Chairman
Graduate Studies Committee
University Biochemistry Group
The University of Calgary
2500 University Drive N.W.
Calgary, Alberta, Canada T2N 1N4.

(NW29)A

Neuropharmacologist

From £8650 p.a. gross *Ware, Herts*

Glaxo Group Research is Britain's leading pharmaceutical research organisation, with a distinguished reputation for developing safe and effective medicines.

Our Neuropharmacology Department is primarily concerned with the identification of novel and improved medicines for the treatment of diseases of the central nervous system, pain and diseases of the gastrointestinal tract.

Applications are invited from neuropharmacologists, who have recently obtained a PhD degree, to join one of our CNS project teams, This position offers considerable scope for innovative basic research and interaction with other neuroscientists in a multidisciplinary environment.

The starting salary will be related to experience. Our generous benefits package includes non-contributory pension and life assurance, participation in Glaxo Group profitability and, where appropriate, generous assistance with relocation to this attractive area of Hertfordshire.

Please apply to: Dr. D. J. Humphreys, Senior Personnel Officer, Glaxo Group Research Limited, Ware, Herts. SG12 0DJ. Tel: Ware (0920) 3993.

Glaxo Group Research Ltd.

Recombinant

DNA Research

As part of its continuing commitment to innovatory research, Beecham Pharmaceuticals is currently engaged in the use of recombinant DNA technology as a means of obtaining human proteins of clinical utility.

We now have a permanent position for a post-doctoral molecular biologist within a group dedicated to cloning, characterisation and expression of human genes. Candidates should have at least two to three years relevant experience in recombinant DNA techniques. Experience of gene expression, though not essential, would be advantageous.

We offer a competitive salary and an extremely pleasant working environment on a 26 acre research site near Epsom Downs. Other benefits include free life assurance, a non-contributory pension scheme, a subsidised staff restaurant and flexible working hours. Furthermore, you will be working for a highly successful British company of international standing. Relocation costs may be paid where appropriate.

For an application form please write to or telephone the Site Personnel Manager, Beecham Pharmaceuticals Research Division, Biosciences Research Centre, Great Burgh, Yew Tree Bottom Road, Epsom, Surrey. Telephone: Burgh Heath 53344 (ext 2207). Closing date: 9th February 1984. (981)A

Beecham Pharmaceuticals

DIAGNON CORPORATION

IMMUNOBIOCHEMIST

Diagnon Corporation, a developer and marketer of diagnostic reagents for clinical laboratories, has an immediate need for an energetic, versatile and creative PhD to serve as Group Leader of our Immunobiochemistry R&D program. Directing an initial staff of 5 technicians, the primary responsibility of the Group Leader is to develop state-of-the-art non-isotopic immunodiagnostic reagent systems utilizing monoclonal antibodies. In addition, the Group Leader will supervise, in the near term, technicians responsible for production of Diagnon's current RIA-based anemia diagnostic products.

The ideal candidate will have a PhD in protein biochemistry with strong training in immunology and a minimum of 5 years R&D experience, including but not limited to, ELISA, IRMA and/or FIA immunoassay development. Significant hybridoma expertise a definite plus.

Diagnon is prepared to offer a very attractive compensation package to the successful candidate for this challenging position with considerable growth potential that reports to the Vice President R&D. If you have an outstanding record of growth and accomplishment in immunobiochemistry R&D, we strongly encourage you to submit your résumé in complete confidence to

Diagnon Corporation
PO Box 960 Dept. 200
Laurel, MD 20707. (NW196)A

CSIRO

Research Fellow

$A24,344 – $A35,806

Division of Entomology
Darwin NT Australia

Field: Biological control of Northern Territory weeds.

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Entomology is a member of the Institute of Biological Resources.

General: The Division is the main centre in Australia for entomological research, which includes programs concerned with pest management. There is an ongoing program in biological and chemical control of Northern Territory weeds in collaboration with NT Department of Primary Production and the Australian Centre for International Agriculture Research. With the financial support of the NT Department of Primary Production, this program is being extended to include studies of week biology and population dynamics.

Duties: To undertake research on the biology and population dynamics of *Mimosa pigra, Sida spp.* and *Hyptis suaveolens* in the Northern Territory. The appointee will be a member of a research team which includes CSIRO and Department of Primary Production staff and will participate in developing strategies for control of these weeds. The research will be integrated with that of other staff working primarily on biological and chemical control. A significant involvement in field studies is anticipated.

Qualifications: A PhD degree in science with emphasis on ecology and population dynamics, or equivalent qualification, together with experience in the field of population dynamics.

Tenure: A term of two years and six months. Australian Government superannuation benefits are available.

Applications: Stating full personal and professional details, the names of at least two referees and quoting reference No M8009 should be directed to:

The Officer-in-Charge,
CSIRO Division of Entomology,
Private Bag No 3,
INDOOROOPILLY QLD 4068.
AUSTRALIA.
By February 10, 1984. (W643)A

Agriculture Research

The Northern Regional Research Center, US Department of Agriculture (USDA) is seeking skilled and imaginative scientists for the programs listed below.

1) Genetic engineering of rumen microorganisms. This research will focus on understanding and using the fermentative and biosynthetic properties of genetically modified obligate anaerobes for improved energy and protein metabolism and fermentation technology. Positions are open for a geneticist, a biochemist, and a microbiologist.

2) Control of Fusaria growth and mycotoxin production. The main emphasis will be on Fusaria and their trichothecene toxins employing genetic and biochemical techniques to define the primary metabolic events that trigger toxin production. Positions are open for biochemists, a plant pathologist and a geneticist.

3) Biochemistry of seed development and maturation in corn. The research will focus on the dynamics and mechanism of partitioning carbon and nitrogen into the biosynthetic pathways that result in protein, lipid, and polysaccharide. Positions are open for plant physiologists and plant biochemists.

This Center employs about 150 scientists engaged in diverse programs of basic and applied research. Benefits include a stimulating professional environment and relocation expense assistance. Salary is based on qualifications and experience, GS-11/12, $25,366 to $30,402. US citizenship is required.

Send curriculum vitaes for position in 1) to Dr. R. J. Bothast; 2) to Dr. R. W. Detroy and 3) to Dr. C. G. Crawford, Northern Regional Research Center, USDA, ARS, 1815 North University Street, Peoria, IL 61604 (309) 685-4011. The USDA is an Equal Opportunity Affirmative Action Employer. (NW197)A

University of Groningen, The Netherlands

junior-level tenured position in the area of biological structures

(vac.nr. 840101)

at the **Department of Chemistry**

Applicants are solicited for a position in the Laboratory of Chemical Physics. Candidates must be capable of developing a research programme employing X-ray crystallographic approaches to address fundamental biological problems.

The succesfull candidate will also be responsible for the computer program package as it is developed and used by staff and students for the determination and the study of large biological structures. Duties will further include some teaching in chemistry.

The Chemistry Department offers a stimulating environment in the area of molecular biology. The Laboratory of Chemical Physics is excellently equipped with rotating anode tubes, diffractometers and camera's, an Evans & Sutherland Picture System 2 with an Enraf Nonius TV-detector/diffractometer to be added soon. A Cyber 170/760 is available at the University Computing Centre.

Preference will be given to candidates under 35 years of age who have completed a PhD.

The salary offered will be between Dutch fl. 3300 - 6500 monthly, before deductions. The position will be available immediately.

Applications:
Applications with curriculum vitae and list of publications should be sent within 6 weeks of the publications of this issue of Nature to:the Chairman of the Personal Department of the University, P.B. 72, 9700 AB Groningen, the Netherlands. (W648)A

elf aquitaine

Research center ELF BIO RECHERCHES Toulouse Labège (south France)

To reinforce one of our young and enthusiastic research teams in biotechnology, we wish to recruit:

1) a **BACTERIAL GENETIST** *réf. N 106*

2) a **MOLECULAR BIOLOGIST** *réf. N 107*

with extensive experience in gene cloning technology,

3) a **BIOCHEMICAL ENGINEER** *réf. N 108*

with industrial experience in animal cell fermentation.

Positions 1) and 2) are senior appointments for which several years post doctoral research experience are required.
Successful candidates will assume full responsibility for their contribution to our multidisciplinary research projects and will be expected to maintain their high scientific level.
Knowledge of french would be an advantage, but is not essential.
Our new, well equipped research laboratories and pilot plants are situated in TOULOUSE near university and government research laboratories. Toulouse has an international airport and is within easy reach of the Mediterranean Coast.and the Pyrenees.

Full curriculum vitae together with a hand-written letter of application should be sent quoting selected reference to:

J. Palmier Elf Bio Recherches BP62 F. 31320 Castanet Tolosan France. (W657)A

MLM Conseil

SENIOR ORGANIC GEOCHEMIST

Division Head Required for Interdisciplinary Exploration Team

Woodward-Clyde Oceaneering, an expanding International Geological consulting firm based in Aberdeen, invites applications from individuals with a PhD Degree and a minimum of five years experience in Petroleum Geochemistry. Responsibilities will include developing and managing geochemical hydrocarbon exploration programmes in frontier basins, both terrestrial and marine, utilising current theories in organic geochemistry. Knowledge of a variety of instrumental methods such as GC, GC/MS, Fluorescence, Pyrolysis and Isotope Ratio/MS is desirable.

This position provides the opportunity of working with a multi-disciplinary exploration team consisting of Geologists, Geophysicists and Engineers. Résumés will be treated confidentially. Please state availability. The successful candidate would be expected to assume duties in March/April 1984.

Salary will be negotiated within the range of £15,000 to £22,500, to be commensurate with experience. Interviews will be scheduled in London and Aberdeen during the week of 30 February 1984. Reply to Box No 925 c/o Nature, 4 Little Essex Street, London WC2R 3LF. (925)A

UNIVERSITY OF GUELPH
ONTARIO VETERINARY COLLEGE
DEPARTMENT OF VETERINARY MICROBIOLOGY AND IMMUNOLOGY

CHAIRMAN

Applications and nominations are invited for the above position which will become vacant on July 1, 1984.

The Department embraces the disciplines of Veterinary Microbiology, Immunology, Epidemiology, and Public Health.

Candidates should possess the D.V.M. degree or equivalent and advanced training to the PhD level in one of the above disciplines.

The ability to administer and lead a dynamic department is essential.

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

Applicants should submit a curriculum vitae, a list of their publications, and the names of three referees.

Applications will be accepted until March 15, 1984 or until the position is filled, and should be submitted to: Dean, Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada N1G 2W1.

Position subject to final budgetary approval. Applications accepted until March 15, 1984. (NW200)A

RHODES UNIVERSITY INSTITUTE FOR FRESHWATER STUDIES

LIMNOLOGIST

Required for a three year contract project on eutrophication and limnology of turbid reservoirs, with the likelihood of extension by two years. The project entails the characterization of nutrient loading rates and the development of limnological management options for the reservoirs.

Appointment from 1 June 1984 or as soon as possible thereafter will be as a Research Officer (R12,657 × 780 — R16,557 × 936 — R22,173 per annum) or Senior Research Officer (R16,557 × 936 — R24,045 per annum) depending upon qualifications and experience, with additional service benefits and assistance with relocation. In addition, a 12 per cent pensionable allowance is payable. Applicants will preferably possess a PhD, and a proven independent research capability. The project will entail regular travel.

Applications with curriculum vitae, representative reprints of publications and names of three referees should be sent to Professor R. C. Hart, Institute for Freshwater Studies, Rhodes University, Grahamstown, South Africa, by 24 February 1984. (W651)A

CSIRO

Senior Oceanographers

$A31,092 — $A42,210
(2 positions)
Division of Oceanography
Marine Laboratories
Hobart TAS Australia

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Oceanography is a member of the Institute of Physical Sciences.

General: The CSIRO Marine Laboratories, which include the Division of Oceanography and the Division of Fisheries Research is Australia's principal marine research institution, employing over 200 scientists and support staff investigating the physical, chemical and biological features, including fisheries, of the oceans around Australia.

Two chartered vessels (53m and 43m) are used for research and a modern oceanographic vessel is being built to replace the 43m vessel. The Marine Laboratories have a VAX 11/750 computer, and on-line access to a Cyber 76 computer is available.

New Laboratories are nearing completion in Hobart.

Duties: The appointees will initiate and conduct research into the dynamics of the ocean, and will be expected to develop interest in processes and phenomena relevant or applicable to the Australian regional oceans, seas, straits, or continental shelves. Depending upon suitability, appointees may be invited to lead groups and develop new research initiatives within Divisional programmes. One appointee may be expected to direct particular interest to the Australian Northwest Shelf region.

Qualifications: A PhD degree or equivalent qualifications with extensive experience and substantial evidence of original research achievement in the field of physical oceanography, or a closely related geophysical descipline. Applicants should desirably have had substantial experience and success in the design and conduct of offshore oceanographic experiments, and the interpretation of their results in relation to available theory and applications; and/or substantial success in the development and verification of theoretical models of ocean or atmosphere dynamics, and a combination of analytical and numberical expertise.

Tenure: Indefinite with Australian Government superannuation benefits available.

Applications: Stating full personal and professional details, the names of at least two referees, and quoting reference Nos A6814 and A6815, should be directed to:

The Chief,
CSIRO Division of Oceanography,
GPO Box 1538,
HOBART TAS 7001.
AUSTRALIA.
By February 10, 1984. (W644)A

ACADEMIC APPOINTMENT IN IMMUNOLOGY

The position is within the Immunology Research Center. The successful candidate will be expected to conduct an independent research program in fundamental or applied Immunology. Opportunities exist as well to participate in research programs already underway in the Center or at the Institut, to supervise and train graduate students, to become involved in production activities and/or to assume administrative duties.

QUALIFICATIONS: A candidate must have obtained a PhD or the equivalent from an accredited university in Canada or elsewere and must have a training in Immunology. Preference will be given to candidates with post-doctoral or other experience indicating that the candidate can pursue his or her research autonomously. Priority will be given to Canadian citizens and permanent residents of Canada. The candidate is expected to possess or to be willing to acquire a working knowledge of French.

LEVEL OF APPOINTMENT: Rank will be determined on the basis of the qualifications and experience and the salary will be according to the scale presently in effect at Institute Armand-Frappier (University of Quebec).

TO APPLY: Send your *curriculum vitae* including a list of publications, 3 letters of recommendation and any other pertinent information before February 29, 1984, to: Service des ressources humaines, Institut Armand-Frappier, 531 boulevard des Prairies, Case postale 100, Laval-des-Rapides, Laval, Québec H7N 4Z3. (NW208)A

THE MACAULAY INSTITUTE FOR SOIL RESEARCH
DEPARTMENT OF MICROBIOLOGY

HIGHER SCIENTIFIC OFFICER/ SENIOR SCIENTIFIC OFFICER

Applications are invited for the post of Higher Scientific Officer/ Senior Scientific Officer to study the microbial transformations of sulphur and trace elements in soil and the availability of these nutrients to plant roots. Candidates should possess a First or Upper Second Class Honours Degree in Microbiology or Plant Science and have a minimum of two years relevant post-graduate experience for appointment at HSO, and a minimum of 4 years at SSO or a post-graduate degree in Microbiology.

Experience in either soil microbiology, plant nutrition, mathematical modelling or with radio isotopes would be advantageous.

Salary £7,149 — £9,561 (Higher Scientific Officer), £8,970 — £11,476 (Senior Scientific Officer), per annum, according to qualifications and experience. Non-contributory superannuation scheme operates.

Forms of application and further particulars of the post may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ, to whom they should be returned by 3 February 1984. Quote Ref. 83/ 17. (966)A

UNIVERSITY OF STOCKHOLM
DEPARTMENT OF ZOOLOGY
Ethologist

Applications are invited for a position as "eo docent" (roughly equivalent to US assistant professor). The position is primarily intended for a person with several years of post-doctoral research experience.

The position is advertised for a period of three years, but is usually renewed for another three year period. Starting salary L 18 (Swedish crowns 113.556 per annum = roughly 9.798 £ or 14.070 US$).

The position is a research and teaching position, and requires a minimum of 75 hours of lecturing per annum and supervision of graduate student research, some administrative duties, and a vigorous research programme. Applicants are selected primarily on the basis of their scientific publications, but teaching experience is also required.

Current research at the division of ethology comprises projects on: mate selection, communication, social and reproductive behaviour in birds, fishes and mammals, control and decision making in animal fighting behaviour.

For further information contact: Professor T Radesäter, Department of Zoology, University of Stockholm, S-106 91 Stockholm, Sweden (Telephone 00946-8340860 ext 322).

Applications including curriculum vitae plus one copy of published, accepted papers, a short summary of the applicants research and teaching experience, names and addresses of three referees and any other papers the applicant wishes to submit should be addressed to The Board of Stockholm University, Fredrik Bloms Hus, University of Stockholm, S-106 91 Stockholm, Sweden, and received no later than March 31, 1984. Quote reference number 79/84. (W661)A

CENTRE INTERNATIONAL DE RECHERCHES MEDICALES DE FRANCEVILLE — GABON

RECHERCHE

VETERINAIRE CLINICIEN ET CHIRURGIEN EXPERIMENTE

Adjoint au Responsable de son Centre de Primatologie

FONCTIONS

* Surveillance sanitaire et soins aux primates et autres animaux de Laboratoire.
* Participation aux différents protocoles de recherche en cours, basés principalement sur la Biologie de la Reproduction.
* Participation à la Gestion du Département.

Excellentes conditions de travail.
Contrat début avril 1984 pour 2 ans renouvelables.
Conditions habituelles d'expatriation.

Candidatures à adresser à Monsieur le Directeur Général du CIRMF, 28, Bd de Grenelle, 75015 PARIS, avec Curriculum Vitae, références professionnelles et prétentions. (W620)A

THE UNIVERSITY OF LEEDS
DEPARTMENT OF ORGANIC CHEMISTRY

SYSTEMS MANAGER

Applications are invited for an experienced person to manage the database in the LHASA program being carried out in the Wolfson CADOS Unit in the Department. This work is being undertaken in collaboration with LHASA UK (LHASA UK is a non-profit making consortium comprising the University of Leeds and leading pharmaceutical and agrochemical companies in the UK to develop the database for a program for computer-aided design of organic synthesis). The Appointee will co-ordinate these activities and help in the provision of a bureau service to users.

Applicants should possess a PhD or equivalent qualification, a good knowledge of synthetic organic chemistry, an interest in computers in chemistry and the ability to work with people.

The appointment will be for a fixed term of one year. It is hoped that further funding may become available from which subsequent appointments may be made.

Salary in the IA Range (£7,190 — £11,615). Appointment may be made at the upper end of the scale for a person with appropriate experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 45/30, to whom applications should be addressed. Closing date for applications 22 February 1984.
(972)A

OREGON STATE UNIVERSITY
GEOPHYSICS

Applications are invited for a 12-month, tenure track position for an Assistant or Associate Professor of Geophysics in the College of Oceanography to complement the present eight member Geophysics faculty. The applicant must have a PhD or equivalent, a demonstrated ability to conduct independent research in theoretical or observational geophysics, and to obtain research funding. Applicants will be considered in most areas of solid earth geophysics. Duties include teaching graduate courses in geophysics, supervising graduate students, and developing a program of grant-funded research.

Interested candidates should submit a résumé, names of three references and a brief statement of research plans by 1 March, 1984 to G Ross Heath, Dean, College of Oceanography, Oregon State University, Corvallis, Oregon, 97331.

Oregon State University, An Affirmative Action/Equal Opportunity Employer, complies with Section 540 of the Rehabilitation Act of 1973. (NW212)A

Pharmacy/ Life Science Graduate

...for an important role in Product Registration

Greenford, Middlesex

We are currently going through a concentrated phase of introducing new products on to an increasing number of markets and this has created a need for an additional registration officer within our busy Regulatory Affairs Department.

You will help to obtain approval for the marketing of Glaxo pharmaceutical products within Central and South America, Eastern Europe, Africa, Middle and Far East Territories. This will necessitate identifying current regulatory requirements and ensuring that all documentation submitted by the Company to the various national authorities conforms with these requirements.

You should be a pharmacy or biological science graduate with at least one year's postgraduate experience, preferably within the pharmaceutical industry. Experience in product registration would be an advantage, but is not essential. You should be able to present scientific information clearly and concisely, orally and in writing, and have the capacity to work under pressure.

The Company offers excellent conditions of employment, including non-contributory pension scheme, bonus schemes, a subsidised canteen and an active sports and social club.

Please write or telephone for an application form to: Mr. R. W. Jones, Personnel Officer, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex, UB6 0HE. Tel: 01-422 3434 ext. 2707 quoting reference number U/510.

ASSISTANT LECTURESHIP IN TECTONICS OR MARINE GEOLOGY/ GEOPHYSICS

University Assistant Lectureship in Tectonics or Marine Geology/Geophysics to be filled as soon as possible. This is a full academic teaching appointment usually held by persons under the age of 30 on appointment and corresponding to the younger end of the national Lecturership scale. Stipend is age linked and ranges from £7,630 aged 25 to £9,425 aged 29.

Further information and applications (10 copies) together with a CV and names of 3 referees to be sent to Dr. P. F. Friend, Department of Earth Sciences, Downing Street, Cambridge CB2 3EQ by 10 February, 1984. (946)A

UNIVERSITY OF KEELE

VICE-CHANCELLOR

The Council and the Senate of the University of Keele wish to appoint a Vice-Chancellor to succeed Dr. D. Harrison, who will take up his appointment as Vice-Chancellor at the University of Exeter on 1st October 1984.

Applicants are invited to write in confidence to the Pro-Chancellor, Lord Rochester, c/o The Registry, University of Keele, not later than 29th February, 1984.

Suggestions of persons suitable for consideration would also be welcome. The University reserves the right to appoint to the post by invitation. Information about the University and further particulars of the post may be obtained from the Registrar, The University, Keele, Staffordshire ST5 5BG. (967)A

TEXAS A&M UNIVERSITY

DEPARTMENT OF BIOLOGY

HEAD

Applications and nominations are invited for the position of Head of the Department of Biology at Texas A&M University.

The Department of Biology, with a faculty of 38, is an administrative unit of the College of Science offering BS, MS and PhD degrees in Biology, Botany, Microbiology and Zoology.

Candidates for the position must have an earned doctorate, a distinguished record in research and teaching, and other professional accomplishments. Candidates are sought who have demonstrated leadership abilities and a commitment to developing strong academic and research programs in Biology.

Candidates should be available to assume the position by September 1, 1984. Nominations and applications, with résumés and names and telephone numbers of references, will be accepted until February 15, 1984 or until a suitable candidate is identified. Materials should be sent to: Dr C J Maxson, Associate Dean, College of Science, Texas A&M University, College Station, Texas 77843. Phone (409) 845 7361.

Texas A&M is an Equal Opportunity Affirmative Action Employer. (NW190)A

POSTDOCTORAL Position available July 1, 1984 for NIH-funded project studying ion transport by liver plasma membrane vesicles. Applicant must have recent PhD and a strong background in membrane transport. Salary support will be provided for two years. Send curriculum vitae and names of three references to: Bennett L Blitzer, MD, Director, Liver Study Unit, University of Cincinnati College of Medicine, 231 Bethesda Ave. (Room 6560), Cincinnati, Ohio 45267. (NW211)A

UNIVERSITY OF EDINBURGH CHAIR OF ANIMAL PRODUCTION

In the Edinburgh School of Agriculture

Applications are invited for the Chair of Animal Production, vacant following the appointment of Professor J H D Prescott to the Directorship of the Grassland Research Institute, Hurley.

The Professor will be responsible for teaching and research in Animal Production Science both within the University Department and the East of Scotland College of Agriculture.

Further Particulars may be obtained from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, with whom twelve copies of the application should be lodged not later than 12th March, 1984. Overseas applicants need supply only one copy of application. Please Quote reference No 12/83. (956)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

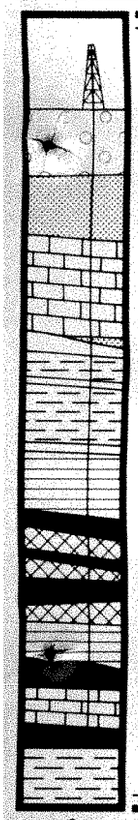
POST-DOCTORAL RESEARCH ASSOCIATE

Applications are invited for the post of Research Associate to work on a project, funded by The Wellcome Trust, on the properties and regulation of dopamine D_2 receptor-effector mechanisms in the central nervous system. The project includes analysis of intra- and extracellular cyclic nucleotides, inositol phospholipid hydrolysis and receptor labelling techniques.

The successful candidate should possess a PhD (or shortly expect to receive one) and have some experience in biochemical pharmacology/neurochemistry. The appointment will be for three years on the 1A Scale for Research Staff (starting salary £7,630 pa).

Applications (with curriculum vitae and the names of two referees) to and further details from Dr S F Nahorski, Department of Pharmacology and Therapeutics, Medical Sciences Building, University of Leicester, University Road, Leicester LE1 7RH, UK (0533) 551234 ext 361

Closing date for applications 15th February 1984. (892)A



POST-DOCTORAL position available immediately to study mechanism of interferon action using recombinant DNA and gene transfer techniques. Previous experience of cell culture and/or molecular biology an advantage. Write to Dr John A Lewis, Department of Anatomy and Cell Biology, Downstate Medical Center 450 Clarkson Avenue, Brooklyn, NY 11203, USA with cv and one letter of recommendation. (NW214)A

Research in Earth Sciences

Opportunities for scientists with 3 years+ research experience

London based

BP Exploration Limited's exploration and development programme is one of the largest, most successful and ambitious in the oil industry. We are now operating in 23 countries including China, Venezuela, Canada, USA, Australia, New Zealand, Egypt and the UK North Sea.

We require scientists with a minimum of 3 years' research experience for the computer modelling groups of our London based geophysical research organisation. These groups undertake research and technical service work in various aspects of seismic prospecting and in less traditional areas such as basin modelling, fluid flow and palinspastic reconstruction.

Applicants must have studied to good honours degree level in geology or physics, but preferably both. They must be able to demonstrate a high level of numeracy, be skilled computer users and be experienced in using large quantities of observational data to validate hypothetical models. A post graduate or doctoral qualification is desirable.

Salaries and benefits are excellent and include non-contributory pension and relocation assistance, where appropriate.

Please write with details of qualifications and experience, quoting ref. U.119, to: Mrs. J. Wilkerson, Recruitment and Placement Branch, The British Petroleum Company p.l.c., Britannic House, Moor Lane, London EC2Y 9BU.

BP

BP Exploration Limited

SILVICULTURE — ASSOCIATE Professor or Professor (tenure track, 12-month). Provide instruction (60%) and research (40%) in silviculture. Teach undergraduate and graduate silviculture course. Conduct research related to extensively managed forest. Opportunity for team research on cooperative programs with industry and federal and state agencies. Earned PhD in silviculture or closely related discipline with one degree in forestry required. Demonstrated teaching and research ability required. Send application, résumé, transcripts and three letters of recommendation to: Arnett C Mace, Jr, Director, School of Forest Resources and Conservation, University of Florida, Gainesville, Florida 32611. Closing date is February 2, 1984. (NW146)A

ASSISTANT PROFESSOR OF BIOCHEMISTRY AND MOLECULAR BIOLOGY

Applications are invited for a faculty position in the Department of Biochemistry and Molecular Biology, Harvard University. Distinction in research and teaching is essential.

Send curriculum vitae, three letters of recommendation, and a brief outline of future research plans before the end of April to Susan Young, Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Mass. 02138.

Harvard University is an Equal Opportunity/Affirmative Action Employer. (NW199)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF ZOOLOGY

Postdoctoral position in Neurobiology available immediately to study the physiology, morphology or pharmacology of local interneurones in the insect central nervous system. The project is expected to be funded by N.I.H. for three years. Salary from £7630 pa depending on qualifications and age.

Send C V and names of two referees to Dr M Burrows, Department of Zoology, Downing Street, Cambridge CB2 3EJ. (927)A

KINGSTON POLYTECHNIC HEAD OF DEPARTMENT OF GEOLOGY

Grade V: £16,035 — £17,736 inclusive of London Allowance

Applications for the above post are invited from geologists who have had substantial experience in research and/or the professional practice of Geology as well as in the teaching of the subject to degree level. The primary task of the person appointed will be to provide academic leadership for the discipline of Geology within the Faculty of Science.

Application forms and further details from the Personnel officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. Closing date 30th January 1984. (979)A

FACULTY POSITIONS IN ASTRONOMY AND ASTROPHYSICS

COLUMBIA UNIVERSITY

The Department of Astronomy and the Astrophysics Laboratory of the Department of Physics at Columbia University plan to make at least four (4) appointments at the assistant professor level, to begin in the summer or fall of 1984. One position in the Astrophysics Lab is for an experimental physicist or an astronomer with an extensive background in instrumentation development to work initially, on funded and planned X-ray and gamma-ray astronomy experiments which will fly on the Space Shuttle and future satellite missions. A second position in Physics is available for anyone with a background and/or interest in high energy astrophysics; research activities currently include analysis of *Einstein* and EXOSAT data, complementary radio and optical observing programs, as well as interpretive and statistical investigations. The Department of Astronomy also has two assistant professor positions open. Candidates with interests in any field of observational and theoretical astronomy are encouraged to apply. Current work in the Department of Astronomy includes observational and millimeter radio astronomy and theoretical investigations in star formation, galactic structure, and the atmosphere and winds of early-type stars. At least one tenure appointment is expected within the next five years, and successful applicants can expect to be considered for this position in due course.

Applicants should include a résumé and letter of interest together with a list of three persons from whom recommendations can be obtained upon request; the letter should state their preference (if any) among the above positions. Columbia University is an equal opportunity employer with a strong affirmative action program, and encourages applications from women and members of minority groups. Mail applications to either Prof. R. Novick, Director, Columbia Astrophysics Laboratory or Prof. L. Lucy, chairman, Search Committee, Department of Astronomy, 538 West 120th Street, New York, New York, 10027.

(NW175)A

UNIVERSITY OF CRETE
FACULTY OF MEDICINE
HERACLIO, CRETE, GREECE

The new School of Health Sciences of the University of Crete announces that the first forty-five positions in the Faculty of Medicine are expected to be filled by the summer of 1984. Application deadlines will be set through the official notification to the published in the Government Gazette and in the Greek daily press, probably in January or February, 1984. This preliminary announcement aims to maximize the opportunities for timely submission of applications by Greeks working abroad as well as within Greece.

The positions are to be filled at all four academic ranks (17 Full Professors, 14 tenured Associate Professors, 11 Assistant Professors and 3 Lecturers), and in all ten departments, namely: Basic Medical Sciences (9), Radiology and Medical Physics (3), Clinical Laboratory Medicine (2), Morphology (4), Social and community Medicine (6), Mother and Child Care (5), Internal Medicine (5), Surgery (5), Neurology and Neurosciences (3) and Psychiatry (3).

Like the successful Schools of Sciences and Humanities of the University of Crete, the School of Health Sciences will place considerable emphasis on excellence in research. The School intends to emphasize both the basic sciences and clinical medicine, and to develop strong programs in community and preventive medicine. Its mission also includes commitment to improved health care in Crete. Construction of a 700-bed University Hospital has already begun.

For further information, please write: Faculty of Medicine, University of Crete, Pervolia, Rethymnon, Crete, Greece or call 3-0831-24069 (Mr. S. Kokkinakis) or 3-01-3610477 (Dr. G. Christakis). (NW210)A

ARC ANIMAL BREEDING RESEARCH ORGANISATION
RESEARCH ANIMAL GENETICIST

A statistical or quantitative geneticist is required to join a research team studying genetic aspects of reproduction and growth in farm animals, with related work on mice. Particular objectives are the study of the causes of genetic variation in reproductive rate and embryo survival in sheep and pigs, and the genetic relationships of voluntary feed intake with rate and efficiency of lean growth in pigs.

The appointee will be expected to conduct experiments on either reproduction in pigs and sheep, or on growth in pigs and mice. The opportunity to play a major part in establishing a new programme of fundamental genetic research with mice may be offered to a suitable candidate.

ABRO adopts a multi-disciplinary approach to genetic improvement and includes geneticists, statisticians, physiologists, biochemists, immunologists and molecular biologists on its staff. Excellent computing facilities are available.

Candidates should have a first or upper second class honours degree in a Biological or Statistical subject with a minimum of two or four years relevant post-graduate experience for appointment at Higher Scientific Officer or Senior Scientific Officer respectively. Salary according to qualifications and experience on the scales £7,149 to £9,561 (HSO) and £8,970 to £11,476 (SSO).

Applications giving full curriculum vitae and names and addresses of two referees to: The Secretary, Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ. (955)A

UNIVERSITY OF STRATHCLYDE
Department of Physiology and Pharmacology

LECTURESHIP

Applications are invited for a lectureship in the Department of Physiology and Pharmacology from graduates in physiology, pharmacology or a related discipline. The person appointed will be required to teach physiology and/or pharmacology to students of various disciplines, to participate in research, and to supervise postgraduate students. Preference will be given to candidates with experience in one of the following research fields: neuromuscular transmission, cardiovascular system, inflammatory mechanisms, smooth muscle, and blood glucose regulation. Expertise in electrophysiology or computing may be an advantage.

Salary scale £7,190 — £14,125 per annum. USS benefit.

Application forms and further particulars (Ref: 69/83) are available from Academic Staff Office, McCance Building, 16 Richmond Street, Glasgow G1 1XQ.

Closing date for applications: 9 February 1984. (968)A

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place, London W2 1PG
DEPARTMENT OF BIOCHEMISTRY
LECTURER OR SENIOR LECTURER

required from 1.10.84. The person appointed will take part in the large teaching programme and must be able to attract research funding. The majority of research in the Department is orientated to clinical, evolutionary or environmental problems; the appointee need not duplicate these interests but should complement them.

Enquiries to Bob Williamson (Tel: 01-723 1252 ext 119).

Applications in form of full cv in duplicate with names and addresses of two referees to Madeleine Jinkinson (from whom further written particulars should be obtained) at above address by 17 February 1984. (960)A

BLOND McINDOE CENTRE FOR MEDICAL RESEARCH
Queen Victoria Hospital
GRADUATE OR POST DOCTORAL SCIENTIST

Applications are invited from graduates in the biological sciences for a position based mainly in the tissue culture laboratory and aimed mainly at defining structure-function relationships of human leucocyte membrane glycoproteins. Experience in tissue culture, particularly in relation to cellular immunology and cell fusion, would be an advantage. Initial appointment is for 4 years. Salary in range £7,190 — £10,710.

Applications (cv and names of two referees) to Professor John Fabre, Blond McIndoe Centre, Queen Victoria Hospital, East Grinstead, Sussex RH19 3DZ. Telephone (0342) 313088. (977)A

UNITED MEDICAL AND DENTAL SCHOOLS OF GUY'S AND ST THOMAS'S HOSPITALS
POST DOCTORAL RESEARCH ASSISTANT

required to work on cell-mediated immune mechanisms in rheumatoid arthritis. Experience in cloning and hybridoma techniques would be desirable but not essential.

The post is funded by the Arthritis and Rheumatism Council until 30 June 1985 and salary will be on the scale of £7,190 — £8,530 plus London Weighting, depending upon age and experience.

Applications in writing, including Curriculum Vitae and names and addresses of three referees, should be sent to the Deputy Secretary, United Medical and Dental Schools, Guy's Hospital Medical School, London Bridge, London SE1 9RT, quoting Ref DM6. (970)A

UNIVERSITY OF MINNESOTA
DEPARTMENT OF ANIMAL SCIENCE
MOLECULAR GENETICIST ASSISTANT PROFESSOR

to develop a gene transfer system i farm animal species; 15 percen undergraduate and graduate teachin and advising; 85 percent research 12-month tenure-track appointment PhD in a Biological Science Research in molecular genetics an recombinant DNA technology Technical competence i microscopy, microinjection cytogenetics and cell cultur desirable.

Submit résumé, transcripts reprints, 3 reference letters an research goals by February 8, 1984 t Dr Alan G Hunter, 495 AnSc/VM University of Minnesota, St Paul MN 55108. Phone 612-376 5676. Th University of Minnesota is an equa opportunity educator and employe and specifically invites an encourages applications from wome and minorities. (NW209)A

DUKE UNIVERSITY
SCHOOL OF MEDICINE
RESEARCH ASSOCIATE

Position available for study of th pharmacology and physiology o hippocampal neurotransmission Candidate must have 2-3 year postdoctoral experience wit intracellular and extracellula recording from brain slices. positio also requires knowledge of amin acid transmitter pharmacology Salary range: $15,500-$16,300.

Send curriculum vitae and thre letters of recommendation to Dr Victor Nadler, Department o Pharmacology, Box 3813, Duk University Medical Center, Durham NC 27710. EOE A/A. (NW163)A

THE QUEEN'S UNIVERSITY OF BELFAST
DEPARTMENT OF PURE AND APPLIED CHEMISTRY
RESEARCH ASSISTANT

Applications are invited fro candidates with a good honou degree or a PhD to work wit Professor R Grigg on synthetic an kinetic studies of new prototrop reactions. Applicants must ha experience in the application of hig field nmr to kinetic problems i organic chemistry and in the use multipulse techniques in structu elucidation.

Salary scale: £6,312 — £8,5 initial placing depending on age an qualifications. Closing date: 1 February 1984.

Applications enclosing a fu curriculum vitae and the names an addresses of two referees should b sent to the Personnel Officer, Th Queen's University of Belfas Northern Ireland BT7 1NN. (Pleas quote Ref 84/N). (983)A

UNIVERSITY OF PENNSYLVANIA
DEPARTMENT OF SCHOOL OF MEDICINE
POSTDOCTORAL FELLOW CELLULAR/STRUCTURAL BIOLOGY

Applications are invited for a post-doctoral fellow, to join our research on the structure, function, and development of microtubule containing organelles and membrane-microtubule complexes. The position is supported by an NIH Training Grant. Facilities and expertise in all aspects of modern structural and cellular biology are available. Send curriculum vitae and names of 3 references to J. M. Murray, Department of Anatomy, School of Medicine, University of Pennsylvania, Philadelphia, PA 19104.
(NW180)A

UNIVERSITY OF CALIFORNIA, BERKELEY
DEPARTMENT OF ASTRONOMY AND ASTROPHYSICS
ADJUNCT ASSISTANT PROFESSORSHIP

Pending final budgetary approval, the Department of Astronomy of the University of California at Berkeley expects to make one non-tenure track appointment renewable up to five years in astronomy/astrophysics at the Adjunct Assistant Professor level, which can start as early as July 1, 1984. Applicants should send a curriculum vitae, bibliography and a brief statement of research interests, and should arrange to have three letters of recommendation sent to Jonathan Arons, Chairman, Search Committee, Department of Astronomy, University of California, 601 Campbell Hall, Berkeley, CA 94720. All materials should be received by February 1, 1984.

The University of California is an Equal Opportunity, Affirmative Action Employer. (NW181)A

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY
Applications are invited for a
POSTDOCTORAL RESEARCH ASSISTANT IN MOLECULAR GENETICS

in a research group examining the distribution and interrelationships of Type II restriction-modification systems. Preference will be given to applicants with a sound training in the techniques of either protein chemistry, or bacterial culture, or recombinant DNA work.

The appointment is for three years from 1st March 1984. The starting date may be held open for an excellent candidate. The salary will be in the Range 1A (commencing between £7,190 and £8,530 pa depending on age).

Applications including cv and the names of two academic referees should be made as soon as possible to Dr N L Brown, Department of Biochemistry, University of Bristol, University Walk, Bristol BS8 1TD UK. (893)A

ASSOCIATE Chief of Staff for Research position available at the Portland VA Medical Center, affiliated with the Oregon Health Sciences University. Responsibilities include administration of growing multidisciplinary research program, coordinating move to new hospital under construction, and maintaining liaison with affiliated programs. Candidates should have a record of nationally recognized ongoing research, background in basic and clinical sciences, and previous administrative experience. MD's preferred. Application deadline March 1, 1984. Send letter of interest, CV and list of 3 references to Daniel E Casey, MD, Chairman, ACOS/Research Search Committee, Psychiatry Service (116A) 3710 SW US Veterans Hospital Road, PO Box 1034, Portland, OR 97207. Equal Opportunity Employer.
(NW187)A

UNIVERSITY OF BIRMINGHAM
FACULTY OF SCIENCE AND ENGINEERING
CHAIR OF GEOPHYSICS AND HEADSHIP OF DEPARTMENT OF GEOLOGICAL SCIENCES

Applications are invited for the Chair of Geophysics and Headship of the Department of Geological Sciences, which will become vacant from 1 October 1984 on the retirement of Professor D H Griffiths. The office of the Headship need not necessarily be linked with appointment to the Chair.

Salary in the Professorial range, with superannuation.

Further particulars available from the Registrar, University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (12 copies: 1 from overseas applicants) should be sent by 13 February 1984.
(900)A

RESEARCH ASSOCIATE OR POSTDOCTORAL POSITIONS

Two positions available immediately for persons with training in molecular biology and/or protein and nucleic acid biochemistry to work on the development of subunit vaccines for important livestock viral diseases. Projects will involve the use of recombinant DNA technology, in particular, the expression of cloned cDNA in prokaryotic and eukaryotic vectors. Salary: $17,000 to $25,000 depending on qualifications.

Send curriculum vitae and three letters of reference to: Tilahun Yilma, Department of Veterinary Microbiology and Pathology, Washington State University, Pullman, WA 99164-7040; phone (509) 335-6011. Washington State University is an affirmative action/equal opportunity employer. Women and candidates from minority groups are encouraged to identify themselves as such.
(NW206)A

YOU'VE GOT A BRIGHT IDEA

for new biological or chemical compounds.

WE HAVE THE CAPITAL

to develop new drugs.

We are not a pharmaceutical firm but a Swiss-based, independant financial group which is prepared to let you participate in a capital venture for the exploitation of your project.

Our objective: the development of new biological or chemical products having previous pharmalogical screening up to the stage of clinical tolerance and efficacy required to permit licensing negotiations.

To obtain all the information required for initial selection, please write in English, French or German to:
DEBIOPHARM S.A. Petit-Chêne 38 – 1001 LAUSANNE (Switzerland).
(W656)A

SAHA INSTITUTE OF NUCLEAR PHYSICS
Calcutta

invites applications from

SENIOR/ JUNIOR PLASMA PHYSICISTS

both in theory and experiment, for a hot plasma program with a medium size research tokamak machine. Areas of interests include researches in the atomic collisional processes, R-F heating and diagnostics in a tokamak plasma.

Send résumé to the Registrar, Saha Institute of Nuclear Physics, 92, A.P.C. Road, Calcutta, India.

D.N. BHATTACHARJEE
REGISTRAR
(W662)A

The Max-Planck-Institute for Psychiatry, Department of Neurochemistry, Martinsried/Munich, Federal Republic of Germany, offers a

POSTDOCTORAL POSITION for Research in Molecular Cell Biology

Applications are invited from scientists interested in post-translational modifications of proteins, particularly tyrosine sulfation, and its role in the sorting and processing of secretory proteins. Preference will be given to applicants with a background in molecular biology/molecular genetics. Appointments starting March 1, 1984, or later will be for two years initially. Salary according to Federal Regulation (BAT IIa).

Applications with curriculum vitae, publication list and names of referees should be sent to Dr Wieland Huttner, MPI für Psychiatrie, D-8033 Martinsried bei München, West-Germany.
(W660)A

UNIVERSITY OF OXFORD
NUFFIELD DEPT. OF PATHOLOGY

Post-doctoral or graduate Research Assistant

Grade 1A or 1B.

A graduate with either a doctorate or a good honours degree is required to participate in a research project on the local and distant spread of human and animal cancer. The work focuses on cell biology and involves cell and tissue culture studies, with reinoculation of cells into animals. Experience of above techniques would be an advantage but is not essential. This work is supported by a grant from the Cancer Research Campaign, at this stage for a period of three years. Salary is up to a maximum of £8,080 dependent on experience and qualifications.

Research Technician

A research technician is required to assist with the work described in the above advertisement. In addition to laboratory procedures such as transplantation and intra-venous innoculation, the post shall involve cell and tissue culture techniques and experience in any of these procedures would be an advantage, but is not essential.

The project is supported for three years at this stage, and the salary shall be on the Whitley Council Scales for Medical Laboratory Scientific Officers, with a maximum starting salary of £6,263 dependant on qualifications and experience.

Applications for either of the above posts, together with names of two referees should be sent to Dr D Tarin, Nuffield Reader in Pathology, Department of Pathology, John Radcliffe Hospital, Headington, Oxford OX3 9DU. Tel Oxford 817797, by 31st January, 1984. (991)A

MEDICAL RESEARCH COUNCIL
Toxicology Unit

TECHNICIAN

Required to work in Laboratory concerned with metabolism of both drugs and natural compounds. The work involves chemical, biochemical and physiological methods.

Qualifications: Degree, HNC or equivalent. Salary according to age, qualifications and experience within the range £5,491 — £7,747 plus London Weighting.

Apply in writing, with curriculum vitae and the names of two referees to: Dr. J. A. Hoskins, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM54EF.

MRC
Medical Research Council

(936)A

THE MATHILDA AND TERENCE KENNEDY INSTITUTE OF RHEUMATOLOGY
Cell Enzymology Unit

POST DOCTORAL SCIENTIST

A recently qualified Post-doctoral Scientist is required for 3 years to work with Drs I Olsen and H Muir on the mechanism of lysosmal enzyme transfer. Experience of sub-cellular techniques and protein/membrane biochemistry would be an advantage.

Salary on the Universities Research and Analogous Staff scales depending on age. London Weighting paid in addition.

Applications with curriculum vitae and names of two referees to The General Secretary, The Mathilda and Terence Kennedy Institute of Rheumatology, Bute Gardens. London W6 7DW. (990)A

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
PHYSIOLOGY DEPARTMENT

RESEARCH ASSISTANT

required to work on a project investigating the secretion of corticosteroids by the perfused adrenal gland. The post is funded by the MRC and is tenable for a period of two years. Applicants should have a degree in physiology or a related subject.

Salary £6,310 per annum plus £1,186 pa London Allowance.

Further details are available from Dr B J Whitehouse, Department of Physiology. Applications stating qualifications, experience and the names of two referees should be sent to Mr J Staight, Assistant College Secretary, Queen Elizabeth College, Campden Hill Road, Kensington, London W8 7AH. (993)A

RESEARCH ASSOCIATE

Position available for a person with at least one year of postdoctoral experience or extensive graduate training in molecular biology and/or protein and nucleic acid biochemistry to work on an immunologic project involving the characterization of intracytoplasmic proteins regulating nuclear DNA replication and the genes coding for these. Salary $15,000 — $20,000 depending on qualifications.

Send a copy of curriculum vitae, bibliography and three letters of reference to: Dr Stanley Cohen, Professor of Pathology, University of Connecticut Health Center, Farmington, CT 06032.

An Affirmative Action/Equal Opportunity Employer M/W/H. (NW186)A

UNIVERSITY OF OXFORD
UNIVERSITY LECTURESHIP IN BIOCHEMISTRY AND TUTORIAL FELLOWSHIP AT TRINITY COLLEGE

Applications are invited for a lecturership to be held in the Department of Biochemistry in the field of Physiological Biochemistry. A medical qualification is desirable but not essential. Stipend according to age on the scale of £7,190 — £15,085. The successful candidate may be offered a stipendiary Tutorial Fellowship at Trinity College. Details of the post from Professor J Mandelstam, Department of Biochemistry, South Parks Road, Oxford OX1 3QU, to whom completed applications (8 typed copies, two from overseas candidates) and the names of two referees should be sent by 25 February 1984. THE ZOOLOGICAL SOCIETY OF LONDON
LABORATORY TECHNICIAN

required to join a project studying lactation and reproduction in seasonally breeding mammals, based at Whipsnade Park Zoo. Applicants should possess a BSc (or equivalent technical qualifications) in Agriculture/Nutrition/Zoology and experience in handling large mammals would be desirable. Driving licence essential. The appointment is for 18 months initially and salary, according to age, qualifications and experience, will be within the range £5,781 to £6,567 inclusive. Please apply in writing by providing CV and names and addresses of two referees to the Establishment Officer, Zoological Society of London, Regent's Park, London NW1 4RY. (980)A

FELLOWSHIPS

UNIVERSITY OF ALBERTA
DEPARTMENT OF ZOOLOGY

Applications are invited for an
NSERC UNIVERSITY RESEARCH FELLOWSHIP POSITION

Applicants should have a PhD degree or equivalent, preferably with postdoctoral experience. The Department is interested in an individual with training and research experience in the field of population biology, specifically aspects of regulation and/or modelling of boreal vertebrate populations. Position will involve some teaching responsibilities appropriate for the specialization of the appointee. Salary commensurate with experience, equivalent to Assistant Professor level, 1983-84 base, $29,720.

Submit complete curriculum vitae with names of three referees and reprints by March 7, 1984 for consideration in the November 1984 NSERC competition to: Dr R E Peter, Acting Chairman, Department of Zoology, University of Alberta, Edmonton, Alberta T6G 2E9, Canada.

The University is an equal opportunity employer but, in accordance with Canadian Immigration and NSERC requirements, priority will be given to Canadian citizens and permanent residents of Canada.

(NW203)E

Fellowships cont on page 22 and 23

POST Doctoral Research Associate. Available immediately to study growth factors and protein kinase. Experience with handling of protein and tissue culture desirable. Send résumés and names of 3 references to: James Tam, Box 294, Rockefeller University, 1230 York Ave, New York City 10021. Equal Opportunity/Affirmation Action.

(NW183)A

MOLECULAR BIOLOGIST

The Divisions of Clinical Immunopathology and Experimental Pathology of the Department of Pathology, University of Pittsburgh School of Medicine, seek a molecular biologist to establish an independent research program. Potential areas of clinically oriented collaboration include human tissue transplantation, lymphoproliferative disease, autoimmunity (emphasizing insulin-dependent diabetes), ageing and immune deficiency diseases. Collaboration is also sought in defining structural and functional properties of the rat major histocompatibility complex.

Please send a curriculum vitae and 3 letters of recommendation to: Bruce S Rabin, MD, PhD, Chairman of the Search Committee, Division of Clinical Immunopathology, Department of Pathology, School of Medicine, University of Pittsburgh, Pittsburgh, PA 15261. (NW198)A

Contamination of Food

Scientific Adviser

This is an opportunity to join a small multi-disciplinary team which provides scientific advice within the Ministry on related topics ranging from nuclear power and radioactive waste management in relation to food, to assessment of the effects of nuclear fall-out on plants and animals. Members of the Atomic Energy Unit are also involved in extra-mural research contracts and are expected to keep abreast of national and international developments in the areas in which they are engaged.

Candidates should have a good honours degree or equivalent in an appropriate scientific subject and experience of the nuclear industry and radiological protection. Familiarity with computer applications would be advantageous.

This London-based appointment will be as Principal Scientific Officer £12,590-£16,180 (including £1250 Inner London Weighting) with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 3 February 1984) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). **Please quote ref: S(A)677.**

Applied bioTechnology Inc.

A MOLECULAR BIOLOGIST AND A VIRAL IMMUNOLOGIST

sought for young firm in Cambridge, Massachusetts concerned with exploitation of recombinant DNA techniques for creation of immunogenic proteins for use as viral vaccines. Research involves development and use of a range of techniques in molecular biology, protein chemistry, virology and immunology. Located near several excellent academic research departments. Two years of post-doctoral experience in related areas desired.

CONFERENCES and COURSES

JAPANESE BIOTECHNOLOGY STUDY TOUR

An in-depth series of site visits, conferences and seminars with some of Japan's leading industrial scientists and executives in biotechnology.

This exclusive study tour is designed to give western scientists and executives an opportunity to become acquainted with the Japanese marketing and research capacity. The mission will be led by Christopher G. Edwards, Editor in Chief of BIO/TECHNOLOGY, and organized by the Technology Transfer Institute. Visits will be conducted throughout Japan from March 31–April 15.

For further information, contact: Technology Transfer Institute—New York, One Penn Plaza, Suite 1411, 250 W. 34th St., New York, N.Y. 10119. 212-947-2648 telex 420057TTIUI. Attention: Mr. Hashizume.

(NW174)C

MOLECULAR ENDOCRINOLOGY AND TECHNIQUES FOR HORMONE ACTION
19 to 25 February, 1984

Course will consist of lectures in methodology with comprehensive syllabus covering receptors, gene transcriptions, mRNA and protein synthesis, recombinant DNA, protein hormones, and cyclic nucleotides.

Co-directors: W.T. Schrader and B.W. O'Malley. Fee: $295/$195 (fellows).

For further information contact: Claudia Payne, Department of Cell Biology, Baylor College of Medicine, Houston, Texas 77030. Tel: 713-799 6200. Deadline 6 January 1984. (NW115)C

CHELSEA COLLEGE
(University of London)
MSc in BIOPHYSICS AND BIOENGINEERING

This is an interdisciplinary course covering the areas in which the physical sciences overlap with medicine and biology. It is open to students with a first degree in a physical or biological science, engineering or medicine. The course, which is approved and supported by the Medical Research Council, is of a two-year duration.

Further details and forms of application for entry in October 1984 can be obtained from: The Secretary, Department of Biophysics and Bioengineering, Chelsea College, University of London, Manresa Road, London SW3 6LX. Tel: 01-351 2488 ext 2382. (992)C

CONGRESS

SAVANNAH '85

FIRST INTERNATIONAL CONGRESS OF PLANT MOLECULAR BIOLOGY
OCTOBER 27 - NOVEMBER 2, 1985
SAVANNAH, GEORGIA, USA

Organized by
The International Society for Plant Molecular Biology

SCIENTIFIC COMMITTEE

J.L. Key (Athens) Chairman	T.J. Higgins (Canberra)	O. Nelson (Madison)
M-D Chilton (Raleigh)	E.J. Jaworski (St. Louis)	J. Peacock (Canberra)
G.B. Collins (Lexington)	T. Kosuge (Davis)	I. Takebe (Nagoya)
N-H Chua (New York)	A. Kondorosi (Szeged)	G. Toennessen (New York)
K. Hahlbrock (Cologne)	C.J. Leaver (Edinburgh)	D.P. Verma (Montreal)

The Congress intends to provide a forum for current research in plant molecular biology in its broadest sense encompassing all of its subdiscipline. It will feature invited plenary speakers, sessions devoted to the various subdisciplines and poster sessions. Anyone conducting research in the scientific areas covered by the Congress is eligible to present a talk and/or poster. Please write: Congress Secretary, 1st ICPMB/The Georgia Center/Athens, GA 30602/USA

Dr. Fred C. Davison
President of The University of Georgia
Honorary Congress President

(NW218)Q

INSTITUTE OF MICROBIOLOGY UNIVERSITY OF DÜSSELDORF FEBS ADVANCED COURSE ON METHODS IN YEAST MOLECULAR GENETICS
June 25-July 10, 1984

The course will cover methods of classical and molecular genetics as used for the study of gene regulation and the expression of foreign genes in yeast. It will include isolation and characterization of mutants, tetrad analysis, use of different yeast vectors, selective and non-selective transformation, construction and use of fusion plasmids. Participants should have some experience in recombinant DNA techniques.

Teaching staff will include: P. Philippsen (Basel), R. S. Zitomer (Albany), K. Breunig, M. Ciriacy, S. Das, J. Gafner, C. P. Hollenberg, Z. Janowicz, R. Roggenkamp (Düsseldorf).

The course will be concluded with two days of discussions including contributions by: G. R. Fink (MIT), D. Gallwitz (Marburg), B. D. Hall (Seattle), F. Messenguy (Brussel), K. A. Nasmyth (Cambridge), F. K. Zimmermann (Darmstadt) and the teaching staff.

Applications including curriculum vitae, publication list, letter of recommendation, and research interests should reach: C. P. Hollenberg, Institut für Mikrobiologie, Geb. 26. 12, Universitätsstr. 1, Universität Düsseldorf, 4000 Düsseldorf, F.R.G., by March 1st, 1984. Applicants will be informed before May 1st, 1984. No accommodation fee will be required but applicants will have to bear the costs of travel and meals. A limited number of travel fellowships will be available. Accommodation will be arranged. (W653)C

GRANTS and SCHOLARSHIPS

UNIVERSITY OF LONDON

EDMUND DAVIS SCHOLARSHIP IN MEDICINE, LAW OR ENGINEERING

Applications are invited from suitably qualified graduates of any university for the award of an Edmund Davis Scholarship tenable from October 1984. Under the terms of the benefaction preference will be given to applicants born in the geographical areas formerly known as Northern and Southern Rhodesia.

The Scholarship is awarded for full-time graduate work at a School of the University for an approved course leading to a Higher Degree of the University. The award is tenable for a period not exceeding three years, and the value will not be less than £2,995 per annum with fees. Travel costs and assistance towards sundry other expenses may also be paid in the case of an overseas scholar.

Detailed information and application forms may be obtained from the Secretary, Scholarships Committee, University of London, Room 21A, Senate House, Malet Street, London WC1E 7HU, with whom completed applications and references must be lodged by no later than 1 March 1984.

(975)H

COMMISSION OF THE EUROPEAN COMMUNITIES TRAINING IN BIOMOLECULAR ENGINEERING

SCOPE: Applications are invited for training contracts (1-2 years) or for short training periods (up to 2 months) from scientists who are citizens of a Member State of the European Communities and who wish to undertake, in a laboratory located within the European Communities, specific research in the field of enzyme or genetic engineering.

CLOSING DATES: Applications should arrive by
- April 1, 1984, for contracts commencing on October 1, 1984;
- July 1, 1984, for contracts commencing on January 1, 1985.

TRAINING CONTRACTS

ELIGIBILITY: Applicants must hold a PhD degree or its equivalent. The training period cannot take place in the applicant's country of citizenship or in the country in which he or she normally resides.

ALLOCATION: In the case of non-employed scientists, the comprehensive monthly allowance to be received by the grant-holder presently approximates 1340 ECU (1). In addition, the Commission will pay an allowance for dependants and will reinburse travel expenses to and from the site of the host-laboratory.
In the case of employed scientists on leave of absence, the Commission will provide the grant-holder with a monthly allocation which complements the salary received by the beneficiary during the training period and includes an additional allowance for expatriation approximating 470 ECU (1) per month.

SHORT TRAINING PERIODS

ELIGIBILITY: Short training periods are designed to offer an opportunity for industrial research scientists (PhD level) to improve their knowledge or to learn a specific technique in public laboratories.

ALLOCATION: The Commission will pay to the grant-recipient a daily allowance of approximately 36 ECU (1) during the length of the training period and will reimburse travel expenses to and from the site of the host-laboratory.

BENCH-FEES

The laboratories undertaking to host the holder of a training contract or of a grant for a short training period will receive a bench-fee, calculated pro-rata to the length of the training period, at 10,000 ECU (1) per year.

INFORMATION

Further details, application forms and lists of host-laboratories may be obtained from Dr. D. de Nettancourt (Tel: (2) 235.40.44) or Dr. E. Magnien (Tel: (2) 235.93.47), Commission of the European Communities Directorate-General for Science, Research and Development, Rue de la Loi 200, B-1049 Brussels, Belgium.

(1) Indicative amounts. Actually, the allocations provided take into account the cost of living in the country where the host-laboratory is located.
As per 1.12.1983, 1 ECU is approximately equivalent to FB/FLUX 45,91; DKR 8,17; DM 2,26; DRA 81,34; FF 6,88; IRL 0,73; LIT 1380; HFL 2,53; UKL 0,57. (W650)H

European Society for Animal Cell Technology
International Association of Biological Standardization

The joint ESACT/ IABS meeting on the PRODUCTION AND EXPLOITATION OF EXISTING AND NEW ANIMAL CELL SUBSTRATES

will be held on MAY 21st-25th 1984
in GARDONE RIVIERA, Italy
The Meeting is organized by:
"Menarini" International Foundation, Florence, Italy
Zooprophylactic Foundation, Brescia, Italy

SUBJECT AREAS: Genetic Engineering or Modification of Animal cells, Characterization of Cell Substrates.

Safety Aspects Relating to the Exploitation of Animal Cells, Oncogenes, Regulatory Proteins, Regulatory Authorities.

Production of Antibody from Hybridomas and the Scale-Up of such Systems.

Developments in Large-Scale Cell Production Equipment.

Medium Developments for Cell and Product Generation.

Serium-Free Media (Pains and Pleasures).
Downstream Processing of Materials Produced from Cultured Animal Cells.

New Product Areas (Lymphokines, Enzymes, Hormones).

Organizing Secretariat: G. F. Panina c/ o FONDAZIONE INIZIATIVE ZOOPROFILATTICHE, Via Bianchi 1, 25125 Brescia — Italy. (W649)M

E M B O

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1984 AWARDS

Next deadline: February 16, 1984

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is February 16, 1984. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on April 27, 1984.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany. (W531)E

VICTORIA UNIVERSITY OF WELLINGTON
New Zealand
POSTDOCTORAL FELLOWSHIPS

Victoria University of Wellington invites applications for these Fellowships, in the following areas in 1984: Chemistry: Carbohydrate medicinal, electrochemistry, liquids, Clay-mineral, Azamacrocycle, Strained-ring compounds; Physics: Condensed matter, geophysics, nuclear physics.

Conditions of Appointment and method of application are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; or from the Administrative Assistant (Appointments), Personnel Office, Victoria University of Wellington, Private Bag, Wellington, New Zealand, with whom applications close on 24 February 1984. (W642)E

FOULKES FOUNDATION FELLOWSHIPS 1984

The Foulkes Foundation provides financial support for recently qualified science graduates with research experience who want to study medicine, and for medical graduates who want to take a science degree. In both cases graduates must intend to do medical research after qualification.

Application forms and further information available from The Registrar, Foulkes Foundation Fellowships, 37 Ringwood Avenue, London N2 9NT, enclosing sae. Closing date — 31 March 1984. (953)E

POSTDOCTORAL FELLOWSHIP PhD, or Equivalent — 2 yr position. To participate in active research program on inflammation, arachidonic acid metabolism in blood vessels. Salary $17,000. To begin Jan-June, '84. Send inquiries, curriculum vitae, and 2 references to: Michael A Moskowitz, MD, Harvard Medical School, Massachusetts General Hospital, Boston, MA 02114 USA. (NW147)E

THE ARKLETON TRUST

1984 FELLOWSHIPS IN RURAL DEVELOPMENT EDUCATION AND CONSERVATION

The closing date for applications for the Ernest Cook and HIDB Fellowships will be 1st May 1984. For further details write to:

THE ARKLETON TRUST, ENSTONE, OXFORD OX7 4HH U.K.
(988)E

FELLOWSHIPS continued

EMBL

European Molecular Biology Laboratory

PREDOCTORAL FELLOWSHIPS

The European Molecular Biology Laboratory is to award a limited number (6-8) of predoctoral fellowships for graduates wishing to study for a PhD at EMBL Heidelberg or its outstations at DESY, Hamburg or ILL, Grenoble. The areas of research in Heidelberg include membrane biology, cellular differentiation, analysis of the structure of membrane proteins and protein nucleic acid complexes and the structure and regulation of genes in procaryotes and eucaryotes. At the EMBL outstations the research centres on the elucidation of biological structures using either synchrotron radiation (Hamburg) or neutron beams (Grenoble).

To be eligible, candidates must hold, or anticipate receiving in 1984, a first or upper second class honours degree, a masters degree or a diplom in biological sciences, physical sciences or mathematics. Preference will be given to candidates from the member states of EMBL and EMBC namely: Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, United Kingdom.

Short listed candidates will be asked to visit EMBL (travel expenses reimbursed) for an interview. Those awarded predoctoral fellowships will be expected to begin working at EMBL in September 1984. The normal duration of the fellowships will be 3 years subject to annual review.

The closing date for completed applications is February 1st 1984. Successful candidates will be notified by the end of April 1984.

Application forms and a catalogue giving further information about the research at EMBL and the groups participating in the Laboratory's predoctoral programme is available on request from Dr J. Tooze, Predoctoral Programme, EMBL, Postfach 10.2209, 6900 Heidelberg, F.R. Germany. (W511)E

UNIVERSITY OF WARWICK POSTDOCTORAL FELLOWSHIP — PHYSICS

The Postdoctoral Fellowship is available under a programme relating to the JOERS initiative.

The appointment is for 3 years and the research programme will be concerned with new glasses for long wavelength optical fibres. The work will involve preparation of the special glasses and investigation of their optical and other properties. The techniques used will include infrared spectroscopy and high resolution electron microscopy.

Applicants should have a strong interest in the physics of materials and should possess or expect to have a PhD in any area related to materials science or solid state physics. Salary on the Research Range IA scale: £7,190 — £11,615 pa.

Enquiries and applications to Professor P W McMillan, Department of Physics, University of Warwick, Coventry CV4 7AL. Closing date for receipt of applications 2nd February, 1984. (962)E

CITY OF LONDON POLYTECHNIC
DEPARTMENT OF PHYSICS
RESEARCH FELLOWSHIP
Polymers and Colloids Research Group

A Postdoctoral Research Fellow is required to work in the above Group. The programme will include the use and development of mainly optical techniques (eg laser light scattering, precision refractometry and turbidimetry) to probe the motions and interactions of polymer molecules and colloidal particles in both the solid and the liquid phase. The research is of both scientific and industrial relevance.

The appointment is from as soon as possible for two years with the possibility of extension for a third year. Candidates should have a research degree.

Research Fellows are currently paid on the scale £8,202 — £8,646 — £9,078 per annum including London allowance.

Further information can be obtained from the Department of Physics, City of London Polytechnic, 31 Jewry Street, London EC3N 2EY. (963)E

PATERSON LABORATORIES CHRISTIE HOSPITAL & HOLT RADIUM INSTITUTE MANCHESTER
DEPARTMENT OF MOLECULAR BIOLOGY
Two Cancer Research Campaign
POSTDOCTORAL RESEARCH FELLOWSHIPS

tenable for three years from 1 April 1984 are available in the new Department of Molecular Biology. The fellows will join a group investigating the molecular biology of Epstein-Barr virus with particular emphasis on the state and expression of the viral genome in EBV-associated tumour cells. Applicants should have a background in a relevant biological science and possess a keen interest in human tumour virology.

Requests for further details and applications, including the names and addresses of two referees should be sent as soon as possible to: Dr J R Arrand, Department of Molecular Biology, 2nd floor, Paterson Laboratories, Christie Hospital & Holt Radium Institute, Withington, Manchester M20 9BX, Lancs. (814)E

Vacant Research Appointments

The Council of the Royal Society invites applications for appointments tenable from 1 October 1984:

1. Two Mr. and Mrs. John Jaffé Donation Research Fellowships, one for research in chemistry and one for research in one of the other physical sciences (including geology).
2. Two Pickering Research Fellowships, one for research in chemistry (especially physical or inorganic), and one for research in plant sciences.
3. The Rosenheim Research Fellowship for research on the biochemistry of plants and the simpler forms of animal life. preference will be given to candidates wishing to study the biochemistry of higher plants.
4. An Eliz. Challenor Research Fellowship for research in physics.

The Head Bequest Committee of the Royal Society invites applications for:

5. The Henry Head Research Fellowship, tenable from 1 October 1984, for original research in neurology in its widest aspects.

The Warren Research Fund Committee of the Royal Society invites applications for:

6. A Warren Research Fellowship, tenable from 1 October 1984, for research in metallurgy, engineering, physics or chemistry or for the use of application of such research or its results in or for industry and industrial development.

Appointments are subject to the Society's General Regulations governing Royal Society Research Appointments, or, for 6, the regulations governing Warren Research Fellowships.

All candidates must have a PhD or equivalent research experience. There are no restrictions on nationality of applicants or proposed places of tenure for 1, 2, 4 or 5. Candidates for 3 and 6 must propose to hold the appointment in any appropriate university department or research institution in the United Kingdom (or, for 6, an industrial research laboratory). Candidates for 6 must be British subjects.

Salaries and conditions of tenure:

1.-4. Salary scale £7,783 × £446 to £10,013 per annum. Tenure for three years in first instance, possible renewal for two further years only.

5,6. Salary scale £10,829 × £466 to £13,159 per annum. Tenure for three years in first instance, possible renewal for two further years only (5). Tenure for five years in first instance, possible renewal for one further year only (6).

For all appointments superannuation benefits will be provided and there will be some provision for research expenses. The point of entry on the relevant salary scale will be determined by Council or the Head Bequest Committee (for 5) or the Warren Research Fund Committee (for 6).

Preferred age limit (on 1 October 1984):
1-4 — Under 26. 5,6 — Under 33
Method of application: Apply (by letter) for application form and further details (*stating for which appointment*).
Address: The Executive Secretary (UMAM), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.
Closing date: 13 February 1984.

THE ROYAL SOCIETY

Royal Society 1983 University Research Fellowships

The Council of the Royal Society invites applications for about 20 appointments to be supported from the Society's parliamentary Grant-in-aid and tenable from 1 October 1984 as Royal Society 1983 University Research Fellowships.

All candidates must have a PhD or equivalent research experience; they must be at least 26 but should not have passed their 33rd birthdays by 1 October 1984. They must be British Citizens (of the United Kingdom) and must hold the appointments in departments of science (including agriculture, medicine, mathematics, engineering and technology) in universities in the United Kingdom. Persons already holding substantive posts in universities in the United Kingdom will not normally be considered.

Appointments, which will be subject to the Society's General Regulations governing Royal Society Research Appointments, will be for up to five years with the possibility of renewal for two successive periods of up to three and two years. Salary will be on the University Lecturers' scale for non-clinical academic and related staff with entry point related to age and London Allowance where appropriate. A basic grant of £900 per annum will be provided for research expenses.

The primary criterion for selection will be the scientific merit of the individual applicant based on his or her record so far and on future potential. Account will be taken of the facilities and intellectural environment being offered by the prospective host department. preference will be given to applicants who wish to hold their appointments in departments which at present have few or no young (i.e. under 35) staff. Each application will need to be accompanied by a statement from the head of the prospective host department who will be asked to confirm that the applicant could be expected to be a very strong candidate for a permanent post at the end of the Fellowship period.

Similar posts may be offered in each of the next three years but the number available cannot yet be indicated.

Candidates who were unsuccessful in 1983 should not be deterred from applying in 1984 if they are still within the required age range. They should, however, make a fresh application on the new (redrafted) application form and arrange for updated statements from referees and the prospective head of department to be provided.

Apply (by letter) for forms for completion by applicant and head of department and further details.

Address: The Executive Secretary (UMAM), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

Closing date: 13 February 1984.

(949)E

WORKSHOP

Three Intense Laboratory Workshops In Nucleic Acid Technology

Chemical Synthesis of DNA Oligonucleotides

Students will synthesize oligos of their own design of length 12-14 bases. The liquid triester condensation method will be employed. The product will be sequenced for verification.

Tuition: $1,000

May 14-23

To apply: Send a brief description of your research interests and the relevance of our course to your plans. Include a brief resumé of your training and institutional affiliation. Please include a contact telephone number. Respond to: Dr. John Newbold, Workshop Coordinator, Program in Molecular Biology & Biotechnology, The University of North Carolina at Chapel Hill, 125 MacNider Building 202H, Chapel Hill, North Carolina 27514. Telephone: 919/966-4161. Application deadline: March 5, 1984. Acceptance notification by March 30, 1984. Inexpensive air conditioned dormitory housing is available.

The Carolina Workshops, May Through July, 1984

Human Genetics/General DNA Technology

General DNA techniques such as subcloning, vector and genomic DNA preparation, electrophoretic analyses, Southerns and nick-translations. Techniques special to human genetics such as in situ chromosome hybridization, linkage analysis, chromosome library construction, and the use of biotinylated probes. Intensive lab work and lectures on the applications of DNA technology to human genetics.

Tuition: $1,200

June 4-20

DNA Sequencing

Extensive experience in chemical cleavage and dideoxy sequencing techniques. High resolution gel electrophoresis (including gradient gels) will be used in sequence analysis. Cloning into plasmid and M 13 phage vectors. Generation of libraries for rapid sequence analysis. Instruction will include computer-assisted analysis of the sequence data utilizing public-access data banks. You may bring your own cloned DNA sample to sequence.

Tuition: $1,200

July 2-18

University of North Carolina at Chapel Hill

Program in Molecular Biology & Biotechnology

(NW193)V

EMBO LABORATORY WORKSHOP ON MICROINJECTION
April 8-13, 1984

Subjects: Microinjection of macromolecules into culture cells, biological assay, reextraction of injected DNA and blot analysis, liposomes, and reconstituted Sendai virus envelopes as carriers for DNA.

Lectures will include invited speakers and course participants. The course is limited to 12 participants. An advance fee of US$ 100, for registration is required.

Applications should be sent to A. Graessmann not later than February 20th, 1984, Institut fuer Molekularbiologie und Biochemie, Freie Universitaet Berlin, Arnimallee 22, D-1000 Berlin 33. (W654)V

INTRODUCTORY WORKSHOPS ON TECHNIQUES IN MOLECULAR BIOLOGY
September 1984

Separate laboratory-based workshops on
(a) PROTEINS
(b) NUCLEIC ACIDS

Details and application forms from Dr. J. Walker, Biological Sciences, Hatfield Polytechnic, Herts. AL10 9AB England. (948)V

GRANTS and SCHOLARSHIPS
continued

MULTIPLE SCLEROSIS RESEARCH

Applications are invited for Grants funded by the Society for research related to Multiple Sclerosis. Support will be provided for approved clinical or epidemiological work as well as for laboratory-based studies within Australia.

Applications from suitably qualified persons will also be considered for Post-Doctoral Fellowships.

Intending applicants for project grants should write for further information to the Executive Director, National Multiple Sclerosis Society of Australia, 616 Riversdale Road, Camberwell, Vic. 3124.

Applications close on Saturday 31st March 1984. Dr E L French (Chairman), Prof D R Curtis (Deputy Chairman), Research Advisory Board, National Multiple Sclerosis Society of Australia. (W647)H

THE NATIONAL KIDNEY RESEARCH FUND

invites applications for renal research grants for consideration at the Meeting on April 17th 1984.

Application forms for these and travel grants available from N.K.R.F. 184B Station Road, Harrow HA1 2RH (Tel: 01-863 4460).

Completed forms required by 5th March, 1983. (920)H

WANTED AND FOR SALE

Scientific and Technical Reviews.
Please inquire for runs or single volumes.

STUDENTSHIPS

THE HANNAH RESEAR INSTITUTE POSTGRADUATE STUDENTSHIPS (Biological, Chemical o Food Science)

Applications are invited for studentships tenable at the Inst for three years leading to a PhD c University of Glasgow.

For the Agricultural and Research Council (AF Studentship, the research area w be selected from: (i) mammary differentiation and turnover; monoclonal antibodies to adipocyte plasma membrane; regulation of glucose utilizatic lactating ruminants; (iv) mole mechanisms of regulatior lipoprotein lipase in mam tissue; (v) colloidal stability of c micelles.

For the United Kingdom Industry Studentship (terms ider to AFRC Studentships) the resc topic would be either: (i) mecha of gelation reactions in milk, c changes in the properties of protein induced by dehydration

Applicants should be citizer the United Kingdom and are req to have, or should expect to obt 1984, a first or upper second honours degree in Biolog Chemical or Food Science.

Further particulars car obtained from the Secretary, Hannah Research Institute, Ayr 5HL, to whom applications, v should contain the names addresses of two academic refe should be sent by 14th Febr quoting ref: PG/84. (96

KING'S COLLEGE LONI RESEARCH STUDENTSH

Applications are invited now research studentships leading t PhD degree in Biophysics for the beginning in October 1984. Biophysics Laboratories, comp the King's College Departme Biophysics and the MRC Biophysics Unit, offer five areas of research: Macromole studies of contractile syst Cellular and developmental n biology; DNA and molec genetics; Cell behaviour and mo Crystallographic and comp graphics studies of biolo molecules.

Applicants need a good hor degree, most likely in biochem biophysics, biological science molecular biology, chemistr physics. A full list of research t and supervisors can be obtained Mr D M Drummie, King's C London, 26-29 Drury Lane, Lo WC2B 5RL, or by telephc 01-836 8851 and asking for Crick. (97

At 65¢ a Volt...

...it's the best buy in Constant Power Supply

The $1295 EC500 was designed specifically to meet the need for a 2,000 Volt Constant Power Supply in special electrophoretic applications such as gel electrofocusing, gel sequencing, SDS gels, and standard slab and tube gels. Check these important features and benefits:

- maximum output: 2,000V; 150mA; 300W
- 3-mode control: Constant Power, Voltage, or Current
- optional voltage limit control for sensitive gels
- dual-range meters and high-low switching without effect on set points
- high voltage safety interlock
- positive electrical protection
- adapts easily to any cell

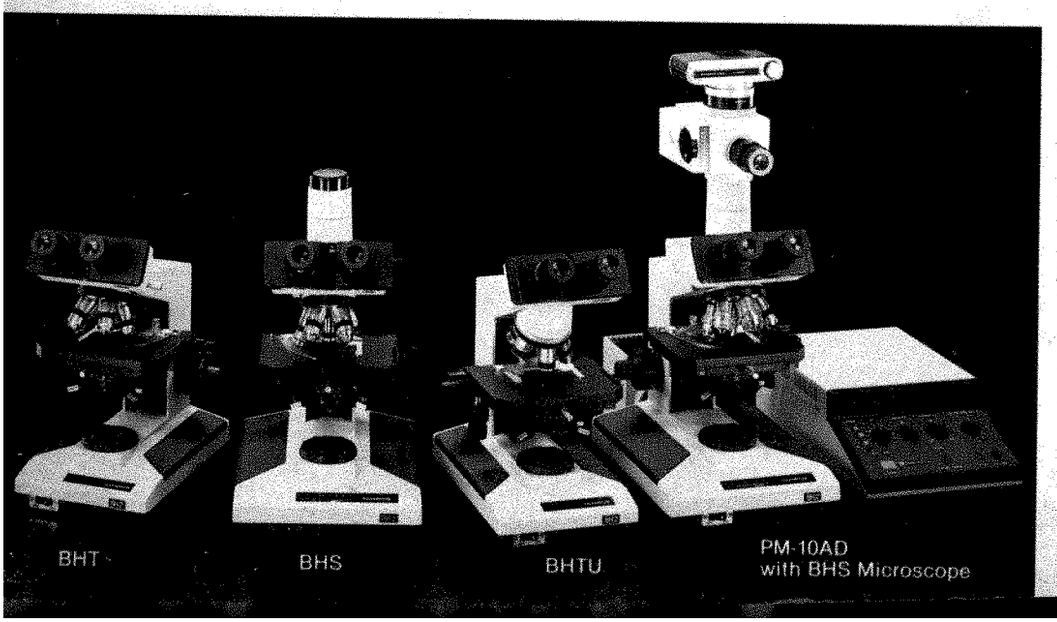
graphy, it pays to match Olympus microscopes with something equ outstanding: The Model PM-10AD The PM-10AD faithfully records th high image resolution, definition a clarity of Olympus microscopes. it does so with the convenience o fully automatic exposure.

The time and effort you save are markable. Thanks to a built-in mic computer and a Silicon Blue Cell (S that relays information to it quickly accurately, you need no longer wo about complicated adjustments.

The automatic exposure range is tremely wide, from 1/5000 of a sec to 2 hours. The microcomputer a matically corrects the reciprocity failure characteristics of the film are using and operates continuou to yield perfect exposures.



The PM-10AD allows automatic a manual operation. In either mode can be used not only for conventic purposes but also for multipl exposures of double-stained fluor cence specimens and panorama photography, in which case unifor density is assured.

Other features:

- Clear digital displays include estimat and actual exposure times, time remai to complete exposure and recall of th previous exposure time.
- Unique vibration-free electromagnet shutter. The contact-free design provi a shutter life of at least 100,000 operat with absolutely no adverse effects on image quality.
- Optional PM-CTR color temperature meter module for simple checking an adjustment of color temperature.

A TRIUMPH OF INSPIRED SIMPLICIT

PM-10AD Photomicrography and Cinemicrography Syste

The PM-10AD is a triumph of inspi simplicity—a simplicity that mean optimum results.

A world-wide scientific research organization for human health and welfare.
A center for promotion of scientific and cultural activities

SERONO SYMPOSIA

Serono Symposia is an independent foundation, created in 1971, to promote scientific research in all disciplines which contribute towards improving human health.
This aim is pursued by means of congresses, courses, seminars and specialized studies.

...f the international congresses scheduled for 1984 are:

...opharmacology
...a, March 8-10
...ic Organization: P.M. Miescher (CH)

...ndocrine Physiology of Pregnancy ... Peripartal Period
...a, April 11-13
...ntific Organization: R.B. Jaffe (USA) – ...ell'Acqua (I)

...roid Disorders Associated with ...line Deficiency and Excess
...iburg, April 24-26
...entific Organization: J. Koebberling (D) – ...Hall (GB)

...tives in Fetal Diagnosis
... May 2-4
... Organization: A.M. Kuliev (USSR) – ...ell (GB)

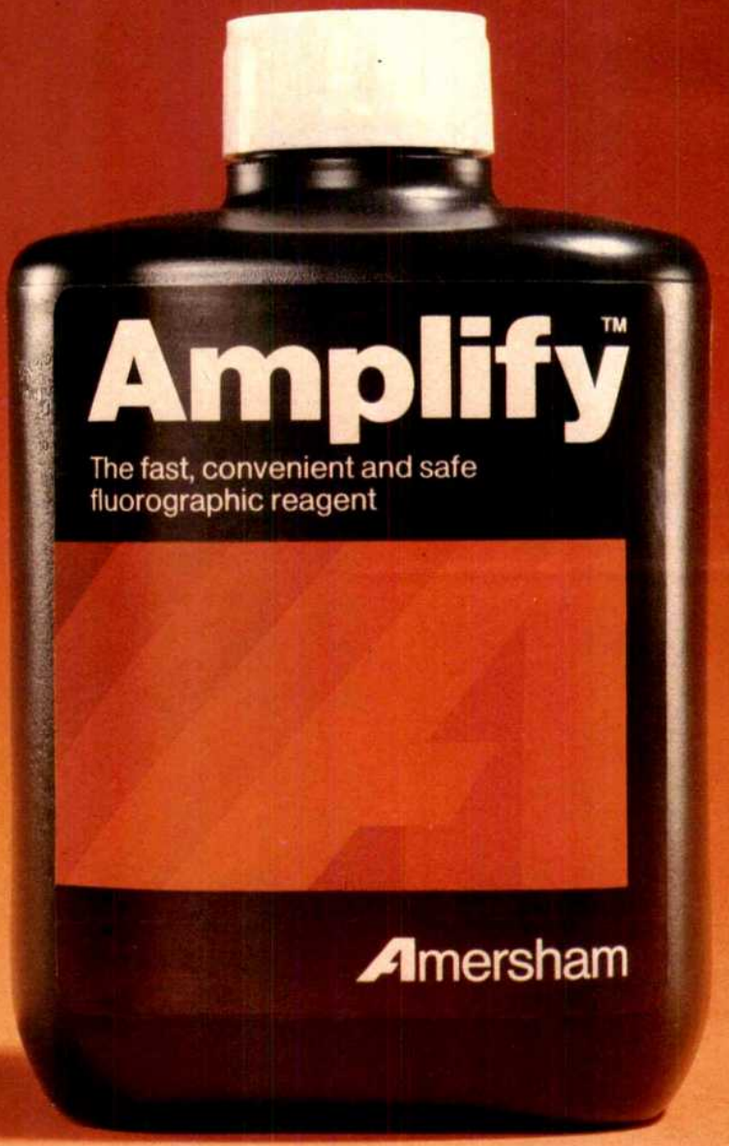
Cytobiology of Leukemias and Lymphomas
Siena, May 24-26
Scientific Organization: D. Quaglino (I) – F.G.J. Hayhoe (GB)

The Adrenal Gland and Hypertension
Padua, June 22-23
Scientific Organization: E.G. Biglieri (USA) – F. Mantero (I)

Reproductive Medicine
San Juan, October 4-6
Scientific Organization: E. Steinberger (USA)

Development and Function of the Reproductive Organs
Rehovot, October 22-24
Scientific Organization: A. Tsafriri (IL)

SERONO SYMPOSIA
CONGRESS CARD
This card entitles the bearer to attend the Serono Symposia throughout the world. Its presentation gives access to all services provided by the registration fee. Valid for 1984



Do you know all the advantages that the Serono Symposia Congress Card offers? Please fill in this form and mail to Serono Symposia for information.

Two Superior Color Indicators

Bluo-Gal

For cloning into the lac gene, choose Bluo-Gal, a histochemical substrate for β-D-galactosidase. As with the widely-used substrate X-Gal, lac$^+$ bacterial colonies are blue in its presence. However, Bluo-Gal contains a unique chromophor that rapidly produces a darker blue color than X-Gal. BRL's exclusive Bluo-Gal is the ideal indicator for M13 cloning and whenever β-galactosidase activity is altered. Already an integral part of the BRL M13 Cloning System, Bluo-Gal now is available separately for the first time.

Circle No. 40 on Reader Service Card.

AMPSCREEN™

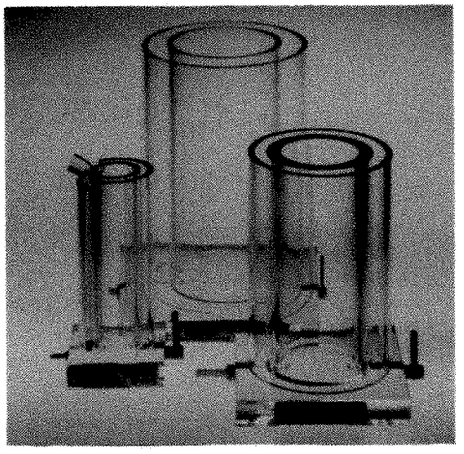
Use BRL's exclusive AMPSCREEN, and detect ampicillin-sensitive recombinant DNA-containing colonies in only 10 minutes without replica plating. AMPSCREEN is a sterile disk, sized to fit into a standard 85 mm petri dish, and treated with a chromogenic substrate. After the colonies growing on a petri dish are blotted onto AMPSCREEN, recombinant DNA-containing colonies remain blue, while non-recombinant ones change from blue to yellow. The complete color change takes place in less than 10 minutes.

Circle No. 41 on Reader Service Card.

DNase I, RNase free

BRL DNase I is free of contaminating ribonucleases, making it ideal for isolating RNA. Isolated from bovine pancreas and purified to homogeneity by affinity chromatography, DNase I degrades DNA to oligonucleotides without degrading RNA or proteins. With each lot of DNase I, BRL provides exclusive lot-specific functional data specifying the amount of DNA digested by one μg of DNase I in one minute at 37°C.

Circle No. 42 on Reader Service Card.



Dpn I

$$5'\text{-}G^{Me}A\downarrow T\quad C\text{-}3'$$
$$3'\text{-}C\quad T\uparrow A^{Me}G\text{-}5'$$

The newest addition to BRL's line of high-quality restriction enzymes is *Dpn* I. *Dpn* I cleaves its recognition sequence *only* when the adenine is methylated, and is especially useful in isolating unmethylated DNA from a mixture of both methylated and unmethylated DNA. Isolated from a variant strain of *Diplococcus pneumoniae*, BRL *Dpn* I is purified free of contaminating nucleases and is qualified as a cloning-grade enzyme.

Circle No. 43 on Reader Service Card.

Save 15% on BRL Gradient Formers January 1 Through March 31, 1984

BRL Gradient Formers provide an inexpensive, easy-to-use means of generating accurate, highly reproducible gradients of aqueous fluids. The compact, concentric reservoir design makes it easy to match fluid heights and requires no cumbersome supports for precise leveling. Each gradient former is individually calibrated and adjusted to assure accurate linear gradients (± 1% of absolute linearity). In addition, concave, convex and exponential gradients can be readily generated. BRL Gradient Formers are available in three sizes, 150 ml, 750 ml, and 2 liter total capacities.

Circle No. 44 on Reader Service Card.

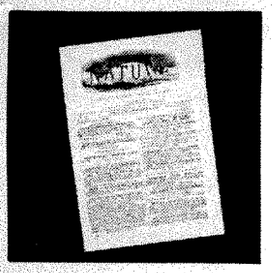
In-House Mycoplasma Detection and Identification

With MycoTect and MycoSpec, available *exclusively* from BRL, you can detect and identify species of mycoplasmas quickly, easily, and inexpensively, right in your laboratory.

MycoTect is cytotoxic to mycoplasma infected cells. After incubation of cell samples with MycoTect and exposure to crystal violet, cell monolayers in uninfected wells stain more intensively and can be easily distinguished from the sparse cell layers found in mycoplasma-infected wells. The entire process takes only five days—less than one fifth the time needed for detection by conventional methods. The cost of a MycoTect assay is only a fraction of the cost of current tests, and the only equipment needed is a 24-well plate.

MycoSpec is a rapid, simple and inexpensive assay for the five major mycoplasma species that account for more than 95% of all laboratory mycoplasma infections. Mycoplasma samples are incubated separately with monoclonal antibodies to each of the five species, then with a biotinylated secondary antibody and finally with a streptavidin-horseradish peroxidase complex. The sample that stains when diaminobenzidine is added contains the monoclonal to the infecting species. With MycoSpec, identification is complete within five hours.

Circle No. 45 on Reader Service Card.



T4 Polynucleotide Kinase

Prepared by an exclusive new method, BRL Kinase is entirely free of contaminating endonucleases and exonucleases and is functionally free of RNase. Each lot of BRL Kinase is functionally assayed for its ability to end-label DNA fragments in both exchange and forward reactions, and data from these tests are provided with every order. BRL provides Kinase in soluble form and, for the researcher's convenience, guarantees the concentration of each lot of enzyme at 10 units/μl.

- Peptide helix termination
- Cultivation of *Plasmodium* parasites in human liver cells
- γ-interferon, immune response and gene expression
- Bushcricket courtship
- Gradual decline of dinosaurs denied

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

TWO NEW reliable, up-to-date and complete biotechnology information resources.

Essential aids for everyone concerned with both the old and new biotechnologies — will save you valuable time and money.

EXAMINE ON FREE APPROVAL WITHOUT COMMITMENT

Detailed information on every aspect of biotechnology worldwide

An indispensable guide to:

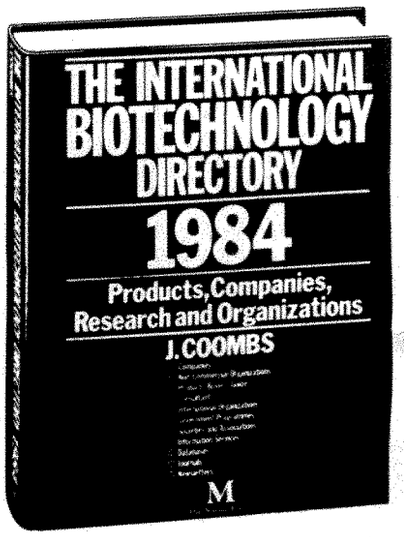
- ★ Products, services and research worldwide.
- ★ Companies worldwide.
- ★ Government and international agencies worldwide.
- ★ Information sources worldwide.

This **new** world directory, compiled by the eminent biotechnologist Dr. Jim Coombs, provides a mass of authoritative information about **the entire biotechnology industry worldwide.**

Unlike other directories, THE INTERNATIONAL BIOTECHNOLOGY DIRECTORY 1984 —

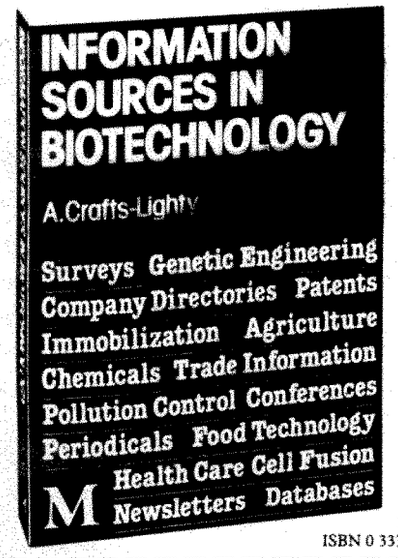
- is thoroughly international
- features a unique BUYER'S GUIDE to products, research and services
- covers both the old and new biotechnologies

The Directory tells you:



- ★ Who your competition is, and what they are doing.
- ★ Who are potential customers and suppliers.
- ★ Where to buy equipment, chemicals and services.
- ★ Where culture collections are located and what cultures they hold.
- ★ Where to get plants built.
- ★ Who imports/exports biotechnology products in over 20 countries.
- ★ What consultancy services are available.
- ★ Which government departments are associated with biotechnology, and their programmes.

Authoritative author



Dr. Jim Coombs is a Member of the Organising Committee of Biotech '83 and of Bio-Energy 1984, and Scientific Secretary of the Third European Community Energy from Biomass Conference 1984. He is editor of *Biomass* and Joint Secretary of the BABA.

The Directory is designed for use across the whole biotechnology industry by scientists and researchers, sales managers, buyers and consultants. Here you will find: over 2,000 organisations — companies, universities and research centres — listed by country. Government agencies and programmes — listed by country. Societies and associations — listed by country. Databases, journals and newsletters — listed alphabetically. Products listed under more than 1,000 headings.

All compiled by Dr. Coombs from a vast array of sources then meticulously cross-checked to ensure the reliability of the data. Now available to you on FREE APPROVAL.

Macmillan Hardcover 400pp
November 1983 ISBN 0 333 35140 1
£50.00/$100.00

The ONLY guide to the selection of cost-effective biotechnology information sources

Evaluates and assesses the whole range of information sources available.

- ★ covers both old and new technologies.
- ★ covers technical and commercial literature.
- ★ covers difficult and hard to trace sources.
- ★ includes over 20 at-a-glance evaluation tables.
- ★ provides an Index of publishers and their addresses.

Dr. Crafts-Lighty, Head of Information and Library Services at Celltech Limited, systematically and critically reviews all the important information sources:

- books • conferences • trade periodicals • research periodicals
- computer databases • patents
- market surveys • directories
- organisations • secondary sources

'Information Sources in Biotechnology' is an invaluable guide to current technical, business and commercial biotechnology information sources for Researchers, Librarians, Information Officers, Businessmen, Investment Analysts, Investors, and Academic Researchers.

Send no money now. Examine on FREE APPROVAL.

You can take both these new books for 30 days examination without commitment. Decide to keep either or both, then simply pay the accompanying invoice. If you are not completely satisfied, just return the book(s) in good condition within 30 days and that will be the end of the matter. Ensure prompt delivery by completing and returning the order form **now.**

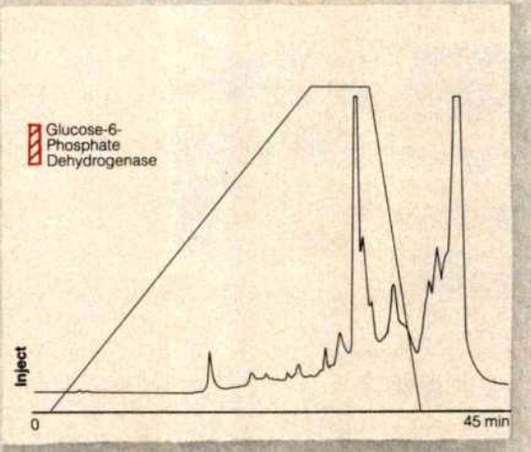
Now isolate and analyze proteins faster, with higher resolution and recovery.

Waters HPLC systems with new ion exchange, gel filtration and hydrophobic packings for biological separations.

High speed gel filtration separation of insulin.

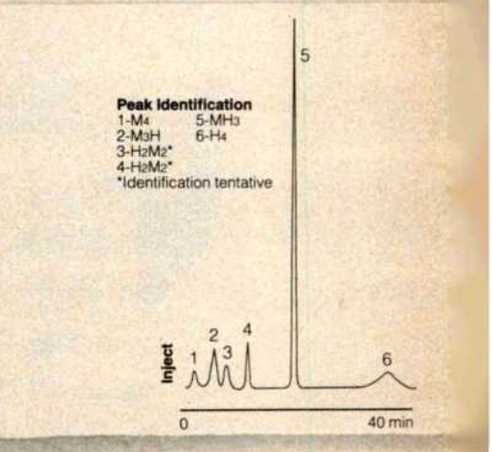


Separation time: 12 minutes.

Waters new high speed gel ration methods allow rapid ctionation of protein samples. is same gel filtration method lets u profile sample composition, olate all components and verify e purity of collected fractions.

mple: 10 µl Insulin, 5 mg/ml
n: PROTEIN-PAK 125
0.1% Trifluoroacetic Acid, pH 2.1
Rate: 1.0 ml/min
tection: 214 nm, 0.5 AUFS

Total recovery of enzymatic activity from a crude bacterial extract using ion exchange.



100% recovery of biologically active protein.

The large pore size of Waters polymeric ion exchange packings (1,000 Å) gives you recoveries of enzymatic activity approaching 100% for even high molecular weight enzymes.

Sample: 100 µl Bacterial Extract, 3 mg/ml
Activity: Glucose-6-Phosphate Dehydrogenase
Column: PROTEIN-PAK DEAE 5PW
Gradient Conditions
Eluent A: 0.02M Tris HCl, pH 8.5
Eluent B: 0.02M Tris HCl, pH 8.5 + 0.5M NaCl
0-100% B, curve 6, 25 min
Flow Rate: 0.5 ml/min
Detection: 280 nm, 0.1 AUFS
Specific Activity Increase: 4.9
Activity Recovery: 100%

High resolution ion exchange separation of isoenzymes.

Complete resolution of LDH isoenzymes.

The resolving power of Waters high performance ion exchange packings provides resolution of the closely related isoenzymes of lactate dehydrogenase.

Sample: 100 µl LDH Isoenzymes, 1 mg/ml
Column: PROTEIN-PAK DEAE 5PW
Gradient Conditions
Eluent A: 0.02M Tris Acetate, pH 8.0
Eluent B: 0.02M Tris Acetate, pH 8.0
+ 1.0M NaOAc
0-100% B, curve 6, 45 min
Flow Rate: 0.5 ml/min
Detection: 280 nm, 0.05 AUFS

Add the performance of Waters HPLC to your separations. And achieve greater success in protein isolation and analysis.

For a demonstration or additional information, contact your local Waters representative or call 617-478-2000 (X 2665).

Transparency at Stockholm

The conference opening this week at Stockholm is another opportunity for arms control. It should keep hopeful ambitions in check and concentrate, instead, on mechanisms for monitoring.

ON the principle that nuclear war is too important to be left to the nuclear superpowers, European states must make the most of the Conference on Disarmament in Europe which opened this week in Stockholm. The signs are that the countries concerned recognize the occasion as an opportunity. But so, it seems, do the Soviet Union and the United States, both of which seem to have taken fright at the breakdown of the arms control negotiations at Geneva at the end of last year, and which have been making noises that may be construed as conciliatory in the past few days. (More accurately, the United States has been making contradictory noises, not unalloyed denunciation, while the Soviet Union has lapsed into silence.) Rarely can states which have by muddled mismanagement lost one opportunity (see *Nature* **306**, 111; 1983) so quickly been provided with another.

The sunny climate in which people appear to have assembled in Stockholm does not, however, guarantee a successful outcome. Indeed, the constitution of the conference is hardly that of a gathering at which tangible agreements could be reached on matters that have not already been fully explored. Altogether, 35 countries will be represented at Stockholm, all of them signatories of the Helsinki Agreements signed in 1975. The gathering is in this sense a kind of relic of a quite different epoch, that in which East–West detente was the touchstone for most international relationships. Almost as they were signed, the Helsinki agreements came to seem more trouble than they were worth. Various people in the Soviet Union, Brailovsky for example, found themselves locked up because they formed the Helsinki Monitoring Group to ensure that high-sounding language agreed at Helsinki was being translated into reality. (Broadly speaking, people's freedom to move from place to place has not been upheld.) As detente withered, a process that began long before the Soviet hegemony over Afghanistan, the successive conferences held within the framework of the Helsinki agreements became increasingly acrimonious, more like opportunities for threatening the withdrawal of cooperation than the recurrent use of that word in the Helsinki documents implied. The meeting that ended last year in Madrid, and which led directly to this week's encounter in Stockholm, showed how ungainly a forum for negotiation such occasions can be. Variously, it was an occasion for mutual recrimination, for flying adventurous but improbable kites — and for some smaller members, Malta for example, to advertise their presence by demanding satisfaction on some peripheral issue as the price of agreement on the date of the next meeting.

Agreement

Helsinki has, however, produced one tangible understanding which is potentially of great benefit to European security, East and West. This is the agreement between all parties that military manoeuvres within 150 kilometres of the boundary between East and West will be notified in advance, and that observers will from time to time be invited by the government concerned. There have been several occasions in the past five years when this facility has helped to steady people's nerves. The fixed element of the agenda for Stockholm is a plan, derived from what was originally a French proposal, to extend this arrangement to cover the whole land surface of Europe and, at the same time, to ensure that military manoeuvres are open to observers from the other side as of right, and not at the discretion of the countries concerned.

In the absence, perhaps a long one, of an agreement on nuclear weapons based in or aimed at Europe (East and West), the prospect of such a lesser agreement is bound to be attractive. Anything, people will say, is better than nothing — and they will be right. Moreover, if the principle can be agreed that all European governments should know what others are doing with their visible military forces, the way may be opened for a more general understanding that the same principle should apply to the more remote strategic components in the uneasy balance — stragetic missiles, long-range aircraft and even lesser weapons of special kinds, nuclear artillery shells for example. That seems to be the objective in the minds of the governments now advocating the benefits of what they call transparency as a first substantial step towards mutual security. The question that must be tackled seriously in the weeks ahead is whether the mechanisms provided by the Helsinki agreements are durable enough.

Conviction

As with all agreements between mutually distrustful governments, it is dangerous to let good intentions outstrip the means of telling that they have been realized. So much is clear from the professed conviction of the United States Administration that the Soviet Union has violated existing agreements on arms control. The administration has in the past few days been telling people in Congress of these transgressions in ways calculated to ensure that what it has to say finds its way into the newspapers before it formally makes them public next week. The snag, with all these allegations, is that the data published to support them are unconvincing. The claims that South-East Asian yellow rain is a vehicle for delivering mycotoxins to innocent people are, as published, unconvincing — but the US State Department falls back on unpublishable intelligence information said to prove the case to the hilt. Much the same is true of the allegations that the Threshold test-ban treaty of 1974 has been violated by the Soviet Union; the data so far published are not necessarily inconsistent with the threshold limit of 150,000 tonnes of TNT equivalent that specified the threshold — but, ironically, the uncertainties might well be removed if only the two sides would formally ratify the treaty and then, as required, exchange the data about seismic travel times in their nuclear testing grounds on which a more accurate assessment might be based. The moral is that the plans now being hatched at Stockholm should be as much concerned with means of verifying whatever may be agreed as with the objectives of agreement.

This, unfortunately, is where the trouble starts. Even the agreement that military manoeuvres in Europe should be notified has been challenged, perhaps inevitably. The objective of any agreement along these lines is to ensure that one government will not mistake another's decision to exercise its military forces as a sign that some kind of attack is imminent, perhaps prompting pre-emptive measures. But who can tell, simply by looking at what happens, the difference between manoeuvres which must be notified and substantial movements of troops and military equipment in the normal course of business, perhaps because of a strategic decision that forces should be differently disposed? This is why the transparency that has become the objective of many European governments will be persuasive (and safe) only if there is some mechanism for making sure that a government suspecting

0028-0836/84/030197-01$01.00

© 1984 Macmillan Journals Ltd

the worst will have access to means of verifying the facts of what may seem a threatening development and then of coming to an understanding of why that development has taken place.

The obvious mechanism is to arrange that a complainant government should have the right to question any other about its intentions, ideally as part of some framework of regular meetings. The trouble is that there will be natural limits on the frequency with which awkward questions may be raised arising from political considerations and even from the unwillingness of governments implicitly to disclose the weaknesses of their intelligence networks. So why not replicate for the monitoring of European forces a system comparable with the nuclear safeguards inspectorate, which in the past decade has made the Nuclear Non-Proliferation Treaty work without substantial complaint? The result, it is true, would be yet another international body staffed by international civil servants, but the value of such an organization would far outweigh not merely its cost but the irritation it would no doubt cause. Moreover, because such a body of inspectors, individually nationals of member states but collectively impartial, would serve as a model for the supervisory authority there would have to be in any more ambitious programme for transparency in Europe than that now planned, its creation would be a more important gain than any other agreement that could be quickly reached at Stockholm.

Mercifully, such an arrangement would also fit in well with the growing belief, at least in Western Europe, that safety from the threat of all-out war cannot much longer be left to the two principal nuclear powers. Little benefit would result from a broadening of the basis of the negotiations on nuclear arms which have broken down at Geneva, which is not to say that the British and French nuclear forces are irrelevant. For if two powers fail to reach agreement, the chances that four (or even five, with China) would do so must be smaller. Yet the construction of some international mechanism for supervising the movement of soldiers and their equipment (and in due course of counting stockpiles?) would go a long way to satisfy European governments that they have a voice in matters which affect them vitally, but over which they have no direct control. □

Pork-barrel supplement

The US Administration hopes to spend more on competitive grants in agriculture. It must insist.

THE word has gone out from those within the Reagan Administration who support competitive grants for agriculture that good news is coming at the end of the month, when the President will release his budget proposals for fiscal year 1985 (see p.204). The competitive grants programme in the US Department of Agriculture (USDA) has been held to a ludicrously low level — $17 million — by political interests which see perfection in the century-old share-the-wealth system that passes for an agricultural research structure in the United States. Every state gets a piece of the action, no questions asked. Congressmen pat themselves on the back for bringing home the goodies. And mediocre researchers continue to grind away at the same old applied technology that might have made sense once upon a time.

The message has finally begun to sink in, however, that questions must be asked if agricultural research is to remain in touch with twentieth-century science. USDA is said to have asked for $50 million for competitive grants for 1985. The obstacle now appears to be the Office of Management and Budget, which is thought to have ensured that only half of that request will see its way to the budget. The administration last year proposed $21 million, which Congress cut back to $17 million — the same level as for years past. The route to real change is not easy. The administration will have to battle with entrenched interests in Congress, particularly one Representative Jamie Whitten of Mississippi, chairman of the House Appropriations Committee and a stalwart defender of mediocrity when it is in the interest of his home state. A half-hearted effort by the administration will not do. It will have to have the courage of its newly-found convictions. □

Examination fever

British school education is in for another shake-up. The minister in charge should move carefully.

SIR Keith Joseph, Secretary of State for Education and Science, has been in his job for what by British standards is a suspiciously long time. Even if the explanation is that there is nowhere else in the government for him to go, the consequence is beneficial. Familiarity with the educational system he administers has now led Sir Keith into a radical reappraisal of how the job should be done. At a conference in Sheffield earlier this month, he announced that his department plans to establish objectives for the main parts of the school curriculum in British schools for children aged from five to sixteen. By doing so, he has issued the most important challenge so far to the doctrine underlying the 1944 Education Act — that central goverment pays for the cost of public schooling, that local education authorities administer schools and influence the curriculum as they can — but that the final arbiters of what is taught are teachers.

This doctrine has increasingly become a fiction in the past four decades. Teachers have done the best they could in a quickly changing world, but have been given too little opportunity to keep up with what they hope to teach. Local education authorities have sometimes done what they could to help, but their performance has been patchy. Bodies such as the Schools Council, conceived of as an instrument for curriculum development but now demolished, have spent too much of their energy on procedure and not enough on content. Central government has had to be content with seeking to influence the system by the reports of advisory committees appointed for special purposes or by the much diminished influence of its inspectors. So, by default, the school curriculum has in effect been determined by the uniquely British examination system. That, it seems, is the discovery which Sir Keith has now made and the circumstance that he seeks to change. The result could be invaluable, especially in the teaching of science.

As things are, much of the British public is not merely ignorant of even the most basic science but actively suspicious of it. Science is often regarded as a necessary evil that will corrupt the minds of children as they lose the innocence of youth, but that children of primary school age should be exposed to such adult material, heaven forbid, seems quite shocking. Even at secondary level, the notion persists that science is an eccentric pastime or, even more demeaning, a vocational pursuit, — a device to enable clever children to pass difficult examinations but remote from the concerns of everyday life. Such effeteness has persisted because, astonishingly, it has never been thought necessary in Britain to specify the basic concepts and information about the world that the school system should aim to teach. Science, while widely taught, is not an essential part of every student's education. Now that may change.

Sir Keith Joseph's intention seems to be to determine what is taught in British schools by reforming the examinations system. There can be no sensible objection to such an attempt, except perhaps the government's desire at the same time to find short-term economies in public expenditure. The argument that teachers should be allowed to adapt their teaching to local needs is no objection, being an obvious truth and not an alternative. That an education system paid for by the British taxpayer should conform with nationally agreed objectives is self-evident.

Yet as things stand, the system does nothing of the sort. At secondary school level, the curriculum is hagridden by examinations. As things are, there are two tiers of school-leaving examinations, one for those seeking places at universities called A ("advanced") level and taken at age eighteen or thereabouts, and a second layer of two examinations at sixteen, called O (for "ordinary") level and CSE (for "Certificate of Secondary Education") respectively. Three years ago, the government agreed to follow its predecessor's undertaking that the examinations at sixteen would be combined, but the details are still being worked out.

0028-0836/84/030198-01$01.00

Meanwhile, the boards that set examinations for sixteen-year-olds continue to devise examination questions that produce a good spread of results correlating positively with the results of other examination questions and which also satisfy the (counter-productive) demand from employers for a wide spread of grades by cramming in such a range of questions that teachers are hard-pressed to cover the syllabus in time. Not surprisingly, education in general, and science education in particular, suffers: the examinations test stamina and quick-wittedness as much as any skill applicable in real life. At primary school level, science education depends on one thing only: whether there happens to be a teacher in the school who knows anything at all about science. Often there is not.

Not content with challenging the historical basis of the school curriculum, Sir Keith Joseph wants also to introduce public examinations that record absolute levels of attainment ("criterion referencing") to replace the present system, which is based largely on the assessment of performance relative to that of others ("norm referencing"). . Practical difficulties aside (who could decide an absolute criterion for, say, appreciation of English literature?), this proposal could easily become a red herring. The year on year correlations made by examining boards ensure that the present system is not totally lacking in objectivity. But the real reason why the present two-tier system of examinations at 16-plus urgently needs unifying is that it is unjust.

The CSE examinations intended for the middle 40 per cent of the ability range have, over the years, become more and more similar in content to those (O levels) intended for the top 20 per cent of the ability range. There are no examinations designed for the 40 per cent of students at the bottom of the ability range although, under pressure from parents and teachers, many of them do attempt CSE. For similar reasons, many who should be taking CSE take O levels. The interest of the student is not best served by pressing him to take an examination in which he will probably score badly. To add insult to injury, those who do obtain high grades in CSE are often deemed by ignorant employers to be inferior even to failed O level candidates. In Sheffield, Sir Keith Joseph seemed to be hinting that he might back away from a commitment to establish a unified system of 16-plus examinations. The clear need is for a single set of achievement-related tests that would be of real value to future tutors and employers alike. An attempt to compromise on this issue could easily be disastrous.

What is it all for? Sir Keith Joseph says he intends to improve educational standards to the point where 80–90 per cent of students achieve the levels now reached by pupils of average ability at age sixteen. The variation of examination performance between schools suggests that this ambitious goal is feasible. To succeed, however, the goodwill of the teaching profession will be needed. Sir Keith's speech in Sheffield, in which he went out of his way to compliment teachers in general, is a welcome sign that he recognizes that reality.

But teachers will need more than a pat on the back. Science achievement in schools is being constrained by inadequate resources, as shown by studies carried out by the Department of Education and Science's assessment of performance unit, while the annual reports of Her Majesty's Inspectors of Schools show that, for example, 60 per cent of schools are inadequately provided with textbooks and 20 per cent have serious equipment shortages. It is arguable that some local education authorities are not fulfilling their statutory obligations under the 1944 Education Act. Even more important, shortages of teachers in key subjects (especially mathematics and physics) have meant that many vacancies are being filled by inadequately qualified people. Poorly motivated and under-confident teachers are unlikely to be an inspiration to their charges.

The reason for this state of affairs is not hard to find. Two years ago, a committee under a the chairmanship of Dr Wilfred Cockcroft established that qualified mathematics teachers, for example, then earned £1,000–£2,000 less per year than their counterparts in industry and commerce. Since that time, circumstances have deteriorated, and the present salary structure of teachers is made incoherent by the problem of falling school rolls.

It is perhaps a blessing that the long recession is not ending quickly, for then the teachers now in posts requiring special skills would be snapped up by industrialists out head-hunting. Sir Keith Joseph now seems to recognize that this problem will not disappear unless there are more resources in the system to keep teachers at their desks — and seems willing to press for extra. Not before time, it will be agreed.

Part of the trouble with the British school education system is that it is commonly regarded as a system on its own, with nothing in common with educational systems elsewhere. Yet this is precisely the time when, in the United States, the federal government has also woken up to the crisis in the schools, has uttered a series of clarion calls for improvement — and has found that the managers of the school systems are ready to respond (at least for a time). In both countries, the underlying problems are very similar, as they are in industrialized Western Europe as well: increasing professionalism in adult work, and the increased demands of the school curriculum, make teaching seem a backwater profession. If it is underpaid as well, the consequences can be calamitous. Teachers with professional skills outside the classroom will simply melt away — or worse, will be replaced by teachers who claim but in reality lack them. In the United States, many school systems have seen the way the wind is blowing, and have chosen to pay the teachers they need to keep above the odds. In Britain, the system of nationally negotiated salary scales will make the solution more expensive. But there is no choice.

That is one battle the minister will have to fight. Another, closer at home, is the battle he will have to fight within a government which, throughout the past five years, has been even-handed in its meanness towards the different sectors of the educational system but, at the school level, has taken advantage of falling school rolls hugely to economize. Now, as the minister seems to have realized, the process has gone so far that students are being denied opportunities that they, and ultimately the rest of us, would profit from. But at a time when public economy is still all the rage (and economically necessary as well), will he be able to wring the funds he will need from his colleagues, and if so, at whose expense? □

You are not what you eat

Too much cholesterol in blood is bad for people; the same is not true in food.

A NEW study from the National Institutes of Health (NIH) on the benefits of lowering cholesterol levels has predictably set off another wave of bad advice from the dietary pundits who have never been able to distinguish between cholesterol in food and cholesterol in blood. What the study did show, and show conclusively, is that high-risk patients — those with blood cholesterol levels over 265 mg per dl — are significantly less likely to have a heart attack if they can reduce those levels to something closer to the US national average of 210 mg per dl. Almost 4,000 men, all members of this high-risk group, were tracked for more than 7 years; all followed a reduced-cholesterol diet, but half were in addition given a drug to reduce blood cholesterol. The test group, which reduced its blood cholesterol levels by about 17 per cent on average, had 24 per cent fewer fatal heart attacks and 17 per cent fewer non-fatal heart attacks than the control group, which managed only a 3.5 per cent reduction in blood cholesterol.

What the study did not show is that the general population would benefit at all by restricting cholesterol in the diet. Early studies, indeed, have shown that it makes little difference whether one's blood cholesterol level is 210 or 230 mg per dl — the benefits that come from reducing blood cholesterol are far from linear. Dietary cholesterol, according to this and earlier studies, makes too little difference to those who really need to do something about the cholesterol in their blood (and who, the NIH study suggests, may well benefit from drug therapy) and is simply irrelevant to those with average cholesterol levels. □

Fast breeder reactors

Europeans sign joint development programme

THE United States may have abandoned Clinch River, but Europe last week confirmed its commitment to the fast breeder reactor. At least, that is one interpretation of an agreement signed on Wednesday by five European states — the United Kingdom, France, West Germany, Italy and Belgium — to open the way to cooperation on fast breeder research and development and commercialization. A more sanguine view is that the agreement is largely a way to reduce the embarrassing £300-million a year cost of European work on fast breeders.

Britain, for example has already announced a cut in its fast breeder programme. Britain's present spending of £108 million a year (1983–84) will fall by a third by 1986–87, according to a spokesman for the UK Atomic Energy Authority, notwithstanding the new agreement (which does not mention cash figures).

Moreover, Peter Walker, Britain's Secretary of State for Energy, said in announcing the agreement that the fast breeder potential (for energy supplies next century) "can be developed only if Europe . . . . is assured that it would provide an economic supply of energy". The memorandum is directed towards this end, he said, and to assuring safety. At the moment, fast breeder electricity is not economic, the costs being estimated to be about double those of a thermal pressurized water reactor.

Nevertheless, the other major partners are pushing ahead rapidly with their own fast breeder construction programmes. In the south of France near Avignon, the 1,200 MWe Superphénix reactor, cooled by a great basin of liquid sodium, nears connection to the grid, and at Kalkar in West Germany the SNR 300, cooled by a sodium loop, should be completed in 1985, and connected to the grid in 1987. The German Federal Government claims to have solved the problem of financing Kalkar by transferring the bulk of construction costs to industry — but it is still financing the fast breeder research and development team at Karlsruhe. This team should also be supported by industry, the government argues, and it hopes that the companies will agree.

Meanwhile the international agreement signed last week will enable the transfer of know-how, technologies and people among the partners. "It would be absurd", said Mr Walker, "for various countries in the European Community to duplicate the research and development work that is needed. The work can be done more effectively and more economically by working together."

Exactly what economies will follow is not clear, but the agreement signed last week is to be followed at a early date by other more detailed agreements covering research and development, industrial cooperation, patenting and industrial property, fuel cycle arrangements (including transport and processing of plutonium) and an inter-utility agreement "to provide for the joint realization of fast reactor power stations and the exchange of operational experience".

It is not thought likely that Britain, at least, would consider building a successor to Superphénix for upwards of 10–15 years. France, too, may find it difficult to support, with the national utility EDF currently facing international debts of FF150,000 million (£12,500 million) and a surplus of electricity. **Robert Walgate**

Asian academy established

New Delhi

A FEDERATION of Asian Scientific Academies and Societies has formally been established with the long-term aim of "solving regional problems without disturbing the natural ecosystem". The idea of such a federation was formulated at a meeting sponsored by the Indian National Science Academy (INSA) two months ago. Appropriately, the formalities setting up the 10-member federation were completed on 15 January, the day before the golden jubilee celebrations of INSA.

INSA, the oldest of India's science academies, though not of its learned institutions (the Calcutta-based Asiatic Society has just celebrated its bicentenary), is the organization responsible for India's international scientific cooperation programme. Guests at the celebration therefore included representatives from many national academies as well as the American Association for the Advancement of Science and the Royal Society of London, all of whom were to address the two-day symposium following the jubilee session.

The main issue at present facing Indian science — the balancing of the pursuit of excellence against the immediate needs of the country — was, however, the keynote of the jubilee session. Professor A. K. Sharma, president of INSA, stressed the need to ensure the academy's autonomy by guaranteeing it an annual budget that would be stable in real terms.

Vera Rich

French fast breeder reactors

Military doubts in France

COULD the new European agreement on fast breeders help France to make more nuclear weapons? On the face of it, such a military interpretation would fly in the face of the agreement, a "memorandum of understanding" which announced that signatories "confirm that activities taking place as a part of this collaboration will be directed to the peaceful development of nuclear energy".

Nevertheless, simply to maintain the security and future of the French fast breeder programme — the main component of European work — is also to maintain the French weapons programme, a vociferous group of French scientists is claiming.

Jean-Pierre Pharabod of the Ecole Polytechnique, for example, claims that the 40 MWth Phénix reactor — a prototype fast breeder power station now to be succeeded by Superphénix — has been used for military plutonium production. Pharabod also says that this fact has been communicated by France to the director of Euratom, the European treaty organization for nuclear research, based in Brussels.

Certainly, France has not submitted inspection of Phénix to the International Atomic Energy Agency (IAEA) — unlike the UK Atomic Energy Authority's Dounreay fast breeder, the PFR, to which IAEA inspectors have been admitted. According to Pharabod, the French military actually need Superphénix (a 1,200 MWe station due on line next year) to fulfil their planned (and announced) expansion of the French deterrent. The number of submarines, now five, each equipped with 16 missiles each with a single warhead, is to increase to seven submarines with the same number of missiles but each with six warheads; and there will be some 200–400 new tactical weapons with yields of some 100–300 tonnes of TNT. (For example, 120 Hades missiles will replace the present 40 Pluton ground-to-ground weapons.)

These developments will need new plutonium, and the arithmetic shows that only Superphénix can provide it, says Pharabod. Thus it is impossible in France to disentangle peaceful from military uses of plutonium, however much the new memorandum of understanding might appear to do so.

Indeed, according to a statement to the French Parliament by a socialist deputy, M. Georges Benedettit, who represents the nuclear area of Marcoule, "the fast breeder is the best choice for assuring both national energy independence and military independence . . . . The fast breeder is the only means now of making plutonium of more than 95 per cent Pu-239 in sufficient quantities to feed the development of our nuclear forces". **Robert Walgate**

US nuclear arsenal

Eight new warheads a day

Washington

MORE than 700 US combat units — over 100,000 troops — are "certified" in the use of nuclear weapons, according to a compendium of US nuclear forces published last week by the Natural Resources Defense Council (NRDC)*. The book, a sort of illustrated catalogue of the US arsenal, offers an unusually complete picture of the full array of tactical and strategic weapons maintained by the United States and of how deeply integrated they are into the US fighting forces. All four military branches — plus the Reserves and National Guard — are trained to use nuclear weapons. Approximately one-half of the 26,000 warheads in the US stockpile are designed for use in battle-field weapons, including antisubmarine and anti-aircraft rockets, air-to-air missiles, artillery shells and even land mines.

Neither the Department of Defense nor the Department of Energy (which has responsibility for production of nuclear warheads) would comment on the accuracy of the data in the book, which was compiled from open sources, including congressional testimony and data obtained under Freedom of Information Act requests. The Department of Energy, however, did advise the authors that publication of the book would be damaging to "the national interest", although it stopped short of taking any legal action to halt publication or distribution.

Some of the most interesting data in the book deal with tactical weapons, which, as co-author Milton Hoenig notes, are not covered even under the stalled SALT and Intermediate Nuclear Forces negotiations. The United States has deployed 5,000 nuclear artillery shells, mostly in Europe, as well as surface-to-surface guided missiles, anti-aircraft missiles, and two varieties of nuclear land mines, known as "Atomic Demolition Munitions" (ADMs). The smaller of these ADMs weighs about 60 pounds and is intended for use by commandos against targets behind enemy lines. It has an explosive yield of as little as 10 tonnes (TNT equivalent). A test of an ADM at the Nevada Test Site in 1955 nonetheless produced a crater 400 feet across and 60 feet deep. Three artillery warheads, for 155-mm and 203-mm guns, are in use, including "enhanced radiation" devices.

The Navy maintains the greatest variety of short-range nuclear arms: ship-launched and submarine-launched antisubmarine rockets, anti-aircraft missiles and surface-to-surface missiles. The Navy is also developing a new air-to-air missile, the Phoenix, to be carried by carrier-based long-range interceptor planes.

The book also provides data on nuclear weapons production, which is now proceeding at the pace of eight new warheads per day; taking into account the warheads retired from service, the result is still a net gain of three per day. According to the book's authors, the US stockpile will grow by 13 per cent over the next five years; by the mid-1990s the arsenal will be approaching the previous peak of 32,000 warheads (reached in 1967) and will in addition have been thoroughly modernized, most warheads having been replaced by new, higher-yield versions.

Future volumes from NRDC will deal with the Soviet nuclear arsenal, arms control and nuclear strategy.

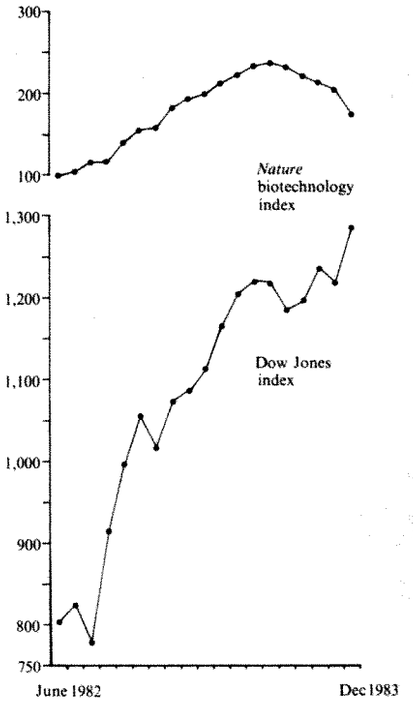
Nuclear reprocessing

West Germany plans ahead

THE West German Federal Ministry of the Interior last week reaffirmed its support for the construction of a reprocessing plant for nuclear waste, in particular "to secure national independence in this area".

The organization responsible is the *Deutsche Gesellschaft für Wiederaufbereitung von Kernbrennstoffe* (DWK) which was formed jointly by the 12 electricity companies concerned. The proposed undertaking will be financed by DWK and will receive no money from the federal ministry.



Approval procedures are now under way for two sites: Dragahn in Nieder-Sachsen, not far from the Gorleben underground storage area, and Wackersdorf, Schwandorf in Bavaria. The procedures should end late this year, when DWK will decide which site it wants. Only final approval by the *Länder* ministries will then be necessary before building starts.

The plan is to build a single installation capable of processing an average of 350 tonnes of spent rods per year, beginning in 1986 and coming into service slowly from 1993 at a rate of 50 tonnes and working up to a final 450 tonnes annually. More than 500 tonnes would overstep environmental control limits.

Meanwhile, the question of costs is causing concern. Electricity from nuclear installations, although it is now cheaper than that from coal-fired stations, already carries a small surcharge to the eventual cost of reprocessing. The revenues collected will accumulate in a fund for the construction of the reprocessing plant. While the cost of the plant is currently given as DM4,300 million (£1,100 million), it could easily rise to DM6,000 million or DM8,000 million before completion, with annual running costs of DM1,000 million. "A reprocessing plant is not an economic proposition", the industry's union spokesman asserted, but nevertheless supported the project as a demonstration of industrial expertise.

Sarah Tooze

The falling index

NATURE's monthly biotechnology index tumbled another 21 points in December 1983 (see 12 January, p.102), falling to 175 against the peak of 238 in July 1983. The index started at 100 in June 1982. During the same period, the overall value of shares on the US stock markets, as represented by the Dow Jones index, has risen dramatically (see graph). Moreover, the decline has been spread across the biotechnology board, affecting 15 of the 16 shares from which the index is compiled. □

Franco-Chinese collaboration

Tibetan expeditions draw breath

THE spectacular French–Chinese geological expedition to Tibet (see *Nature* 5 January pp.17–36), is unlikely to be repeated — at least for a few years. The problem is not one of politics but of resources according to the expedition's French organizer, Claude Allègre of the Institut de Physique du Globe in Paris.

The expeditions, which have revealed that the high plateau of Central Asia was created by a succession of intercontinental collisions and not just one, "have been a huge effort for both sides" says Allègre. There were three separate expeditions, in 1980, 1981 and 1982. Each involved 50 big trucks in the field, and 150–200 people. France put in some of its best geologists. Chinese resources — both people and cash — were especially stretched.

As a result, no further major French–Chinese expeditions to the area are

planned, but Allègre believes that the Chinese will not be seeking collaboration with other partners either. Meanwhile, however — while both sides gather breath — France and China will mount small joint expeditions each year, the next to the Ping Ling mountains.

In any case, Allègre says, "we've understood what we wanted" about the region. While there is much more to learn, only a third of the results of the expeditions have been published so far and the teams need a few years just to think about the results.

Why had only France been involved in the expeditions, and not other Western countries? Partly, it may be because other geologists were less enthusiastic than Allègre about the exercise. Dan McKenzie of the University of Cambridge, for example, one of the pioneers of plate tectonics, says that while the expedition had been important and useful "I feel one ought to do simpler, cheaper things". If expensive, deep seismic studies were the object then the French–Chinese expedition would have been perfect to do the job, and would have done it well. But there was "no good gravity study" of the Tibetan plateau, for example, a lack that could be rectified much more cheaply. Moreover there were other plateaus in the world which were more accessible to western geologists, says McKenzie: for example eastern Turkey, the Colorado plateau, and the Alteplano. Also, relations with China were improving to the extent that person-to-person partnerships could now be arranged, McKenzie feels, rather than vast government-backed expeditions — and in fact McKenzie is going to China on such a partnership this Easter.

Allègre says he had sought European collaboration when there were plans to continue beyond the first three years, probably with other European countries taking up the running from France. But while individual geologists had shown great interest, none was prepared to organize the collaboration with the Chinese, Allègre claims.

Perhaps this was wise. Allègre describes the negotiations that led up to the expeditions as "terrible", and as having been several times on the point of breaking down. The Chinese drove a very hard bargain, which has led — for example — to the French team leaving several major instruments behind.

Allègre clearly does not relish entering such negotiations again. The result, however, was fair to both sides, he feels. Allègre says he cannot estimate the overall cost, but it had been shared equally, he claimed.

President François Mitterrand of France himself has shown real interest in the expedition, Allègre says, and by no means only in its politics. The President reveals a "greater and greater interest" in science, not only as a means to develop the French economy. Allègre, who accompanied Mitterrand on his 1983 tour of China, says that Mitterrand asked him more about plate tectonics than about science politics.

As a result, Allègre considers that while French science is not as well blessed as promised by the former research minister Jean-Pierre Chevènement, the budget is "protected", and will be in the future. Mitterrand has a very balanced view of the relation between basic and applied research, Allègre believes — more balanced than his ex-minister. **Robert Walgate**

Nature conservancy

UK unit lives hand to mouth

A REQUEST by the British Nature Conservancy Council (NCC) for extra funds to help restore the value of its research budget seems certain to be turned down by the UK Department of the Environment. NCC has asked for £200,000 towards its survey and monitoring programme, but the department has responded by suggesting that research is an area where particularly stringent savings are expected. NCC's grant from the department for next year, now under negotiation, will be announced later this month.

NCC's research programme has been steadily eroded since 1973, when the council was established as an executive body distinct from the Natural Environment Research Council. NCC research is now worth roughly half as much in real terms as in 1974. This is an untoward consequence of the Rothschild customer/contractor principle, by which some civil science research is commissioned by government departments. As, in recent years, the cost of salaries in NCC has, like that in other government departments, consistently outstripped the allowance made for it, the amount left over for research has declined. NCC also labours under an accounting peculiarity whereby it has to meet the cost of its staff pensions from its own funds.

Within a declining research budget, the amount NCC spends on research commissioned from the research councils has declined even faster. According to Sir Ronald Mason's investigation into government commissioned research, carried out for the Advisory Board for the Research Councils (see *Nature* **306**, 102; 1983), the amount spent with the Agricultural and Food Research Council and the Natural Environment Research Council fell from £1.3 million to £0.3 million in the five years to 1982–83 (1983 prices). One reason for the shift seems primarily to have been cost: NCC has found it more economical to employ young researchers on short-term contracts than to hire senior scientists who would often insist on working to a higher standard than was needed. The total annual cost of all NCC research is £1.5 million.

NCC now has to satisfy itself with a very pragmatic approach. According to its chief scientist, Dr Derek Ratcliffe, any possibility of commissioning basic research has long since been abandoned, and there is no chance of turning back the clock to the days when NCC's forerunner ran an experimental station of its own. All that NCC retains is a small group which spends most of its time providing site management advice to NCC local officers, and some survey teams. Most of NCC's resources are tied up in "renotifying" owners of Sites of Special Scientific Interest (SSSIs — see *Nature* **306**, 525; 1983) and survey work aimed at identifying new SSSIs is a long way behind schedule.

Despite the gloomy outlook, NCC's chairman, Mr William Wilkinson, has been working hard to secure more research funds. It is felt that NCC needs hard factual information on sites to be able to make an authoritative case for their notification. **Tim Beardsley**

Molecular biology

UK to stay in Europe

BRITAIN'S Medical Research Council (MRC) has advised the Advisory Board for the Research Councils that the United Kingdom should adopt a whole-hearted commitment to the European Molecular Biology Laboratory (EMBL) in Heidelberg, West Germany. The news has come as a relief to EMBL, which has lived under the threat of a possible withdrawal of UK support ever since the Advisory Board for the Research Councils asked MRC to consider the benefits of UK participation in EMBL just over a year ago. The board will consider MRC's advice on 31 January.

The MRC view is based on a detailed assessment of the benefits and costs of UK participation in EMBL and the scientific merits and cost effectiveness of the research carried out there. The assessment, carried out by a group of five senior British scientists, concluded that the case for remaining in EMBL is strong on scientific grounds alone and remains strong even when costs are taken into account.

The group is not persuaded that the £1.2 million contributed by MRC to EMBL in 1983 (£1.5 million is due this year) would have purchased "an equivalent amount of work of equal quality" within the United Kingdom but does believe that EMBL's value for money should be increased.

The group recommends a more effective system of peer review and cost accounting for each of EMBL's scientific programmes but acknowledges that Professor Lennart Philipson has moved in the right direction since becoming director general of EMBL in 1982. It strongly approves of his new system of financial management of programme budgets, hopes and anticipates that costings will be linked to scientific reviews of the programmes but remains doubtful that the procedures for scientific review are adequate.

The problem, the group claims, is that the Scientific Advisory Committee of EMBL, which is charged with advising the laboratory council on EMBL's scientific programme, is in danger of being "seen as a creature of the director general" rather than offering independent advice to which the director general should be free to reply. Again, it welcomes Professor Philipson's moves to avoid such criticism but wants them further discussed and extended.

To judge the cost-effectiveness of EMBL, the MRC group chose to compare it with the MRC Laboratory of Molecular Biology (LMB) in Cambridge. The figures, summarized in the accompanying table, confirm suspicions that staff costs in Heidelberg are double those in Cambridge. The group considers that differential to be inevitable, given the salaries at comparable laboratories, notably the European Organization for Nuclear Research (CERN) near Geneva, and the allowances expected by expatriates on short-term contracts. It also considers the greater recurrent costs at EMBL to be justified and points out that expenditure on consumables is equivalent in the two laboratories. The only way to cut costs, the group implies, would be to reduce staff — if stringent peer review revealed weaknesses.

The MRC group's view of the current scientific programmes at EMBL is that, like the curate's egg, it is good in parts. The cell biology programme excels and the outstation programmes at Institut Laue-Langevin, Grenoble and the DESY synchrotron in Hamburg are good. On the other hand, the recent investment in a differentiation programme is speculative and that on molecular structures is too large. Both instrumentation programmes are thought to be somewhat contrived to meet the original aim of EMBL to develop unique and expensive technology that few national laboratories would touch.

Costs at EMBL compared with LMB

	EMBL 1982	LMB 1982-83
	(£ thousands) per head	
Staff costs		
Salaries	16.2	9.3
Allowances, insurance, etc.	5.5	2.4
Total	21.7	11.7
Extra costs		
Consumables	5.4	5.2
Recurrent	8.4	6.6
Total	32.9	18.1

Total EMBL expenditure for 1982 was £9.4 million of which 54.7 per cent was spent on the cost of 232 "man-years" of staff. Total LMB expenditure for 1982–83 was £4.6 million of which 47.3 per cent was spent on the cost of 186 "full-time equivalents" of staff.

Overall the MRC group argues that the benefits the United Kingdom receives from participating in EMBL outweigh those of withdrawing, even if there would be a short-term financial gain in doing so. Professor Philipson, who is generally pleased with the report, questions whether there would be even a short-term gain, once proper account was taken of the cost to the United Kingdom of redeploying many of the British nationals (about 20 per cent of the total) employed at EMBL. Mr D. Noble, MRC under-secretary, claims that the group's calculations did include that possibility.

Noble also said that MRC would be surprised if the Advisory Board for the Research Councils did not accept its recommendation to continue UK participation in EMBL. He hoped that the board would now see fit to advise the UK Government that its science budget should be adjusted to protect the MRC budget against losses at the expense of increased contributions to EMBL due to changes in the UK economy.

Peter Newmark

UK public health

Pathogens for suburbia?

Two laboratories at the UK Centre for Applied Microbiology and Research (CAMR) at Porton Down, in Wiltshire, England, may be closed in order to reduce costs. The two laboratories, the Special Pathogens Reference Laboratory and the Environmental Microbiology and Safety Reference Laboratory, carry out a varied programme of research in viral diagnosis, the production of vaccines and viral safety testing.

The proposal to close the laboratories is one of the options to be considered at a meeting of the Public Health Laboratory Service Board, on 26 January. Routine diagnostic work and possibly some safety work may be transferred from Porton to the new Central Public Health Laboratory building under construction at Colindale, in North London. Dr C. Gordon Smith, chairman of the Public Health Laboratory Service Board, says that a number of proposals will be discussed but stresses that none has yet been examined in detail and that no decisions have been made.

The news that diagnostic work might be moved to London nevertheless made front page news in the *The Standard* of London, under the banner headline GERM LAB PLAN FOR LONDON. Laboratory diagnosis of viral diseases, including Lassa fever and smallpox, has in fact been carried out at the existing Public Health Laboratory building at Colindale, which includes a high containment laboratory, since 1946. A statement issued by the Public Health Laboratory Service and the Department of Health and Social Security to calm the fears of Colindale residents says that "research involving highly dangerous organisms" will not be transferred to Colindale.

Among the staff of the threatened laboratories at Porton there is concern of a different kind. The work carried out there includes research on Ebola virus, Lassa fever and Marburg disease, and is aimed at reducing reliance on animals in diagnosis and producing vaccines. Botulinum toxoids and anthrax and experimental whooping cough vaccines are also manufactured.

Porton staff hold that closure of the laboratories or partial transfer of some of the work to Colindale cannot be justified financially, and point out that experimental work is probably better carried out in a remote area.

It is far from certain whether the Health and Safety Executive would allow some of the work to be transferred to London. The staff at Porton say that they represent a national asset that becomes invaluable in an emergency and may spawn products of commercial value and complain that CAMR seems likely to be hit harder than other Public Health Service laboratories.

US research computers

Agency expects funds to buy time

Washington

GRANTS from federal agencies allowing US researchers to purchase computer time are about to become respectable again. President Reagan's budget for 1985, to be published at the end of the month, will include substantial new funds with which the National Science Foundation (NSF) can help grant-holders to purchase time on supercomputers — machines such as the various models of CRAY computers. But the new funds will fail to satisfy at least two of the groups that have been urging that academic researchers should have more ready access to computer power.

One of these is the working group of the National Science Board (advisory to NSF) which last summer recommended that $200 million should be spent over the next three years on ten supercomputer centres for university researchers. The new NSF programme will fall far short of that proposal, both in the amount of money available and because it is intended that the new funds should be used to buy time on existing machines.

Budget prospects

DR Edward Knapp, director of the National Science Foundation, refused to comment last week on the other components of the NSF budget, but did say that he expected NSF to do as well as last year. The budget for the current fiscal year, published last February, gave NSF an increase of 18 per cent, the largest increase in a single year in the foundation's history.

Speaking on Monday at the National Academy of Sciences, however, Dr George Keyworth, the President's science adviser, did drop a hint about NSF's plant biology budget in the context of his general optimism about funding for agricultural science. Keyworth said that the plant biology programme at NSF had received a budget increase of 16 per cent last year, up to $50 million. "I'd look for comparable growth again next year", he said.

Keyworth was not nearly so specific in discussing the competitive grants programme at the Department of Agriculture, although he did reveal that Secretary of Agriculture John Block had discussed the programme directly with the President and had received Reagan's personal support.

Even so, the new programme will mark a major shift of NSF policy on computing. Not since 1972 has NSF supported computer centres on campuses, while most federal agencies continue to baulk at paying the full cost of purchased computer time under research grants. During the same period, this policy was abetted by researchers themselves, who preferred to buy their own mini- and microcomputers than to use central computing facilities which, according to the working group, had fallen into disrepute.

Some of the consequences of that trend have been unfortunate. The National Science Board's working group concluded last summer that "important" research is not being tackled for lack of supercomputer facilities in the United States and cited the case of an astrophysicist who had found he could get access to the computing power he needed only by collaborating with a West German group. Under the new budget proposals, researchers will be able to buy time on CRAY and other computers such as those at Los Alamos and Livermore National Laboratories.

The new programme will nevertheless offend those who greeted the National Science Board's report with scepticism, saying that the supercomputer was a solution in search of a problem — and that the important applications of these machines are few. Meanwhile, an alternative policy is suggested by the work of a group of researchers at the California Institute of Technology (Caltech) who are developing what may prove to be cheap supercomputers. According to Geoffrey Fox, the theoretical physicist who directs the Caltech project, and Charles Seitz, a computer scientist, the few hours of computer time that a researcher may be able to buy with NSF funds will not add significantly to the computer power already at his or her disposal.

Fox says that "an IBM personal computer is more cost-effective than a CRAY" and that a few hours of CRAY time will not crack any problem that cannot be solved on a personal computer in a few hundred hours. What worries Fox is that under the new policy, supercomputer time "will be chopped up so that everyone will get a few hours. But you don't chop up Palomar into a pixel for each observer; I've never understood why we do that in computing."

The Caltech approach, according to Fox and Seitz, could give academics access to dedicated supercomputing power by cutting costs dramatically. They have already built a machine using 64 microprocessors of the kind used in personal computers with a power one-tenth of a CRAY machine but at only one-hundredth of the cost (about $80,000).

The Caltech programming philosophy is also different. While CRAY machines have several processors that operate in parallel when the program-compiler identifies steps in a sequential program that can be executed simultaneously, the Caltech approach would parcel out steps in the solution of a problem to its separate processors. In the 64-chip version of the machine, each processor can communicate with six others and thus be kept running almost full-time.

At Caltech, the next step is to expand the desk-top 64-chip machine to a total of 1,024 chips. This would be equivalent to a CRAY machine in computing power but because of the use of mass-produced chips may cost only one per cent as much.

Stephen Budiansky

French research

Academics between millstones

RESEARCHERS in French universities who receive support from the Centre National de la Recherche Scientifique (CNRS), the principal research council, will soon have to "clarify" their position in relation to the university and CNRS. This follows an agreement last week between CNRS and the ministry of national education (MEN) which seeks to disentangle the sometimes complex relationships between research groups and their sponsors that have grown up through years of benign neglect, and a series of individual, idiosyncratic agreements between CNRS and individual groups.

Whether or not this will be seen to aid research depends the observer's point of view. It will certainly aid research management, and it will also aid university management — for in the past, university presidents have not always known what their own groups were doing. A new contract between a group and CNRS might commit the university to new overhead (providing laboratory space, for example) without the university having had any say in the matter.

On the other hand, however, the situation gave individual scientists the chance to play off one part of the bureaucracy against another in the game of raising a grant. Under the new agreement, this will be harder, and there will be fewer corners where researchers not conforming to national policy can find rest.

The outline agreement describes "the ancient links, many and narrow" between CNRS and universities and claims that these justify "an effort of clarification and organization". The two sides have sought "precise texts" and "a common charter", which would be "legal, rational and balanced".

Under the charter, CNRS will draw up a general agreement with each university (or grand école), followed by a series of particular agreements with each group in that establishment, these particulars being placed in the context of the general agreement. The establishment as a whole will bear responsibility for applying the agreement, something that should give a university president more power in his (or her) own house (provided the president can control the new three-committee management structure of the university, a prospect which some French researchers find unlikely).

Making science a good read

SIR — The leading article "Must science be impenetrable?" (*Nature* **305**, 477; 1983) concluded that little or nothing could be done to improve the situation, and that the authors are the most obvious culprits. I argue that the poor quality of illustrations contributes towards impenetrability, and that on this point the editors are the culprits.

The decipherment of a figure that contains more than one part can be very laborious, because the pertinent information is often buried in an overcrowded legend. This could be avoided if the following rules were applied:

(1) When the graph includes more than one line, identify each by appropriate labelling.

(2) When the figure contains several panels with the same abscissa and the same ordinate, usually identified as (*a*), (*b*) and so on, indicate on each panel its experimental specificity.

(3) Whenever possible, use the same symbol for the same experimental condition in all comparable figures throughout the article.

(4) When several symbols need to be used in a graph, use the open circle for the control condition; for instance, if an experiment has been performed without (o) and with (●) an addition or a treatment, use the symbols as indicated. (The open

circle is the simplest symbol available, and its "emptiness" suggests that nothing has been added.) Rule (4) should prevail over rule (3) when these two rules are in conflict.

(5) Make the labelling of abscissa and ordinate as precise as possible. For instance, it is preferable to write "Time after drug addition" than simply "Time". Also express results in moles rather than in c.p.m. or in absorbency units, sparing the reader the task of doing the conversion. If results are given in per cent, give the value of 100 per cent in standard units in the legend.

(6) The legend should be as short as possible, and could sometimes be restricted to the title since, ideally, the figure would be fully intelligible without making reference to the legend.

From my own experience of the biochemical literature, I know that, if labelling of figures is still very limited, it is because it is systematically discouraged by subeditors, whose policy is to push all the information into the legends. With modern technology, the cost of lettering can no longer be an excuse for this negative attitude.

Université Catholique de Louvain and International Institute of Cellular and Molecular Pathology, UCL 75.39, Avenue Hippocrate 75, B-1200 Brussels, Belgium

Nicotine delivery

SIR — The concern of the British Royal College of Physicians (*Nature* 1 December 1983, p.418) with smoking and health is justified and well directed towards the immediate problem of reducing the number of people who may be influenced by cigarette advertising. The problem though, is that cigarette smoking is a means of drug delivery that is both crude and effective. If one assumes that some number of people in any society want to use drugs for a variety of reasons and that smoking is merely a way of delivering an addictive drug, the problem becomes conceptually simpler.

Addiction to the natural alkaloid nicotine is widespread and social tolerance of the drug and its users is such that for years a debate existed over whether chronic users were actually addicted in the same sense as opiate users. Semantic differences apart, smokers mostly smoke to deliver nicotine to their mucus membranes so it can be absorbed into the blood.

Alternative routes of drug administration more cosmetic than chewing tobacco or snuffs should be developed so that the nicotine addict has alternatives to cigarettes. Nicotine chewing gum has had limited success, but may soon become available worldwide. Another alternative might be transdermal application much in the manner of nitroglycerine and scopolomine patches. Nicotine "inhalers" might also be feasible if dosage could be adjusted.

I would appreciate receiving correspondence from individuals or groups actively engaged in finding alternative methods of nicotine delivery in humans.

Prudent antibiotics

SIR — A leading article in *Nature* in 1981 (*Nature* **292**, 661) referred to the publication of the "Statement Regarding Worldwide Antibiotic Misuse", which was signed by more than 200 physicians and scientists and intended as an alert to the problem of antibiotic abuse.

The article raised the question of how the problem would continue to be addressed. The response generated by the statement enabled the Alliance for the Prudent Use of Antibiotics (APUA) to be established at the end of 1981. Its members include physicians, scientists, medical and public health personnel and members of the general public from more than 50 countries. The alliance has adopted a positive rather than a negative approach by advocating and defining good usage. Its activities include the gathering and dissemination of information and education on antibiotics and their use. The alliance has begun to organize a network of groups and individuals who are working in their own countries to improve antibiotic usage. The *APUA Newsletter* has opened a line of communication among the members. We recognize that it is at the level of the consumer — patient, physician, farmer, gardener, pet owner, beekeeper — that the rational use of antibiotics must be understood and accepted.

It is our long-range objective to implement changes in the use of antibiotics which will preserve their therapeutic effectiveness.

STUART B. LEVY
Alliance for the Prudent Use of Antibiotics, PO Box 1372, Boston, Massachusetts 02117, USA

Gripes of wrath

SIR — I read Walter Gratzer's review of Fowler's *Modern English Usage (Nature* 10 November 1983, p.134) and was both saddened and amused at the examples he quoted of uncouth English.

My own pet irritation is the use of 'in the order of" in place of "of the order of". This has become very common, but I do not recall ever coming across it more than twenty years or so ago. I believe it is an example of a phrase that "escaped" from scientific usage, was mangled by those who do not understand the meaning of order of magnitude, and then was hypnotically readopted by all because of the frequency of its appearance in the distorted form.

Other pet aversions of mine include "anticipate" when "expect" is meant (we anticipate completion by the end of the year), and the introduction of a quite inappropriate conditional qualification (symposium programmes are available in the foyer if delegates care to help themselves).

Finally, an ambiguity in a classified advertisement seen many years ago which never fails to amuse me when I recall it: Miss E. Brown, wardrobe dealer, having cast off clothing of all descriptions, invites inspection.

DENNIS PIPER
Abingerwood, Ewhurst, Cranleigh, Surrey GU6 7SJ, UK

Publishing "in conference"

SIR — I should like to draw attention to an alarming trend in the biological literature — the reporting of scientific data at conferences followed by publication of the abstracts in journals where they acquire the cachet of fully refereed papers.

During a recent literature search (using the BIOSIS 80 system) the key words "Ia antigen", "interferon", "macrophage" and "prostaglandin", in various combinations, elicited a total of 33 references for 1980-82 of which 19 were abstracts from conference proceedings. This struck me as being overbalanced. I do not question the validity of the data or the integrity of the investigators, but it is not possible to assess a piece of work from a 300-500 word abstract which, presumably, has not been refereed.'

The two major "offenders" in my small sample were, coincidentally, both American, in particular, abstracts from the annual meeting of the Federation of American Societies for Experimental Biology published in *Federation Proceedings* and the annual meetings of the American Federation for Clinical Research published in *Clinical Research*. Such abstracts are subsequently extensively quoted in the literature and may be the only source for the work being discussed.

This trend seems to have come about because of the greatly increased numbers of scientists wishing to publish and the consequent increased pressure for space in conventional journals, the pressure on conference organizers to include all submitted abstracts and the increased use of poster sessions — impossible to referee. The overload of submissions is made worse by the apparent tendency of conference organizers to base their acceptance of registration on whether or not the applicant wishes to submit an abstract.

An example of these trends has recently been seen in the British Pharmacology Society, where data used to be presented as a talk and, following discussion, refereed "on site" by a show of hands from the members of the society. If the authors wished it the abstract was then published in the *British Journal of Pharmacology*. With the introduction of poster sessions and the consequent reduction in the possibilities for adequate reviewing, the society now publishes abstracts as a supplement to its journal — a laudable attempt to indicate the comparative lack of refereeing.

The trend towards publication of abstracts only is disquieting. A solution will not be easy to find, touching as it must the "publish or perish" syndrome. The simplest solution would be not to publish abstracts of meetings — perhaps a little drastic. Or the editors of the relevant journals could ask for a fuller abstract of the work presented to be adequately refereed before publication.

While it is not possible to blame scientists (myself included) from taking this easy road to publication, the inclusion of unrefereed conference abstracts in subsequent articles where they acquire the same pedigree as fully detailed and refereed papers should be viewed with some unease as this practice is open to considerable abuse.

• Perhaps data-banks should admit as search criteria Boolean specifications such as "not abstract".— Editor, *Nature*

India's bait

SIR — I sympathize with the Indian Government's attempt to lure expatriate scientists and doctors back home through programmes such as TOKTEN and through the proposal to create a sophisticated technological city (*Nature* **305**, 350; 1983). But short-term solutions such as these are not the answers. India needs a coherent science policy and infrastructure to stem the flow of brain-drain and to lure the expatriates. As a first step, I suggest revitalization of the universities with up-to-date curricula facilities and competent indigenous and expatriate teachers.

I graduated from Kerala University in 1965 with a BSc in chemistry, but without having had the opportunity to use even a *p*H meter and without having been exposed to many of the fundamental principles of chemistry. When I joined the Training School of the Atomic Research Centre (Bombay) immediately afterwards I was confronted with advanced chemistry concepts (which at first went over my head), and a plethora of sophisticated instruments. I literally had to burn the midnight oil to bridge the almost inseparable gap between the university and the research centre.

I strongly urge the Indian authorities to rejuvenate science education in universities throughout India (not just in Bombay, Delhi or Madras). When the universities become centres of excellence, the expatriates will return home without the need for baits. One need only recall how Nalanda and Taxila, two excellent centres of learning in ancient India, attracted even foreign scholars to India.

SIR — We would like to add a few of comments concerning the creation of a UN biotechnology centre and India's bait for expatriates (*Nature* **305**, 350; 1983). We are of the opinion that many of the Indian scientists and doctors working abroad would like to go back to India. We would like to point that a recent survey by E. Garfield (*Sci. Public. Policy* **10**, 112-127; 1983) has shown that India is the "superpower" of Third World countries in scientific research.

The establishment of a biotechnology centre in India, either at New Delhi or Bangalore, would attract many of the Indian scientists working abroad to return to their country and promote science. For this reason, we urge UNIDO to reconsider India as a site for such a centre.

The announcement by the Prime Minister, Mrs Indira Gandhi, of the plan for a "technology city", where Indian scientists now working abroad would be able to work in conditions to which they have become accustomed, is a constructive step towards bringing scientists of Indian origin back to India. The return of meritorious scientists to India would create a competitive and productive environment for those already working in Indian universities and other research centres.

Grains of truth

SIR — D.A. Williams claims in his letter (*Nature* 1 December 1983, p.420), that those who attended the Royal Astronomical Society discussion meeting on "Are interstellar grains bacteria?" were impressed by McDonnell's photographs of interplanetary dust in which silicate crystals were visible. He also claims that Hoyle conceded that interstellar bacteria are not alive. In point of fact Hoyle only said, in response to a question, that he had never claimed that they were alive, which is not quite the same thing.

Related to this point is the argument that bacteria would be photodissociated on scales of the order of 1,000 years. However, similar arguments were put forward by chemists to refute the suggestion that there were molecules in interstellar clouds — a position no longer held as shielding mechanisms ensure the long-term stability of organic interstellar molecules.

McDonnell's photographs do not show any evidence of the depletion of interstellar grains but only of the high velocity impacting interplanetary dust (micrometeorites), and were therefore irrelevant, as McDonnell suggested in his opening comments. Indeed the one thing that was held to be clearly disproved at the meeting was that the 10-micrometre feature was not due to siliceous material.

Exotic nuclear decay discovered

The discovery, nearly a century after Becquerel, of a novel mode of radioactive decay is a surprise, but one that confirms α decay as the chief means by which heavy nuclei shed mass.

THOSE who decorate their offices with wall charts showing the isotopes, stable and otherwise, of the elements are in for trouble. As things are, these elaborate diagrams usually show by means of a colour scheme of some kind which radioactively unstable nuclei decay by which means. Decays in which the α– or β-particles (electrons) are emitted predominate, but the diagrams must also make room for other less common processes — positron emission, internal conversion (of an electron in an inner shell) and even fission. Now the same wall charts will have to accommodate radioactive decays in which unstable nuclides emit substantially heavier nuclear fragments than the familiar α–particle.

That is the burden of the discovery (see p.245) reported this week from the University of Oxford by H.J. Rose and G.A. Jones of a handful of unmistakable carbon nuclei among the decay products of radium-223 (^{223}Ra), hitherto marked in the charts as a simple α–emitter with a half-life of 11.2 days. What they have shown is that ^{223}Ra nuclei occasionally, but significantly, decay with the loss not of an α–particle but of a carbon-14 (^{14}C) fragment. Anthropomorphically, from the point of view of the nucleus so to speak, this novel arrangement has obvious advantages. The decay scheme of ^{223}Ra involves the successive emission of three α–particles (to give radon-219, polonium-215 and lead-211) followed by an electron, to give bismuth-211. (This decay scheme, which begins with uranium-235, predominantly leads to lead-207 by the further emission of two α-particles and an electron.) So why should not an unstable ^{223}Ra nucleus shorten this tortuous process by eliminating a substantial part of the charge and mass that must ultimately be lost in a single package? What now emerges is that that option is not as rigorously forsworn as the conventional wall charts suggest.

So how can it be that the best part of 90 years has passed since Becquerel's discovery of radioactivity before it has been recognized that α- and β-emission are not the whole of radioactivity? That is the obvious question that will now arise. The proper response, as a glance at the article by Rose and Jones will show, is that the discovery of ^{14}C emission from ^{223}Ra, important though it is, serves chiefly to emphasize that α-particle emission is the chief means by which radioactively unstable nuclei lose mass. Indeed, in the observations now reported, there are roughly 1,000 million times as many α-particles and ^{14}C nuclei in the decay of ^{223}Ra, perhaps as vivid a proof as there could be of the dominance of the familiar mechanisms of decay.

The rarity of these events is also the explanation why this novel form of radioactivity has not previously been found. So much can be told from the account by Rose and Jones of their observations, which entailed more than half a year of running time with detectors arranged so as to distinguish between single ^{14}C fragments and more frequent occurrence of groups of three α-particles from the nearly simultaneous decay of separate ^{223}Ra nuclei. (The fact that one of the two detectors seems at one stage to have been put out of action by accumulated radiation damage is a telling measure of the numbers of α-particles involved, even if the fault appears to have been an ambition to avoid buying new material for this purpose.) In the circumstances, there is no reason to think that the discovery that ^{223}Ra can decay with the emission of a ^{14}C particle will quickly be followed by similar observations in respect of other nuclei. Rose and Jones say they are looking at another candidate nucleus, but there will be few groups with the stamina that compels competition.

Some, no doubt, will even ask whether this search for exotic and necessarily rare mechanisms of decay can be worth the trouble, now at least that it has been demonstrated that such mechanisms are not entirely excluded. The simple answer, as always, is that the neglect of phenomena on the simple grounds that they are only rare, or that their effects are small, is never justified. On this occasion, several important questions arise, not the least of which is why the first exotic fragment to have been found in the decay of a radioactive nucleus should have been the unstable ^{14}C nucleus and not the stable ^{12}C, itself simply a combination of three α-particles.

Superficially, the calculation of the rate of some specified radioactive decay is a simple problem in elementary quantum mechanics, often found in introductory textbooks. An α-particle, for example, can escape from an unstable nucleus only if it can tunnel through the potential barrier against disintegration caused by the nuclear forces that hold even unstable nuclei together. The chance that if such a particle exists within the nucleus it will then escape, or the rate of the corresponding disintegration process, is thus a function of the height of the potential barrier, its width and of the total decrease of the potential energy of the system once the disintegration has taken place.

This calculation, first made in simple form by Gamow, has more recently been much refined and accounts for the "Gamow factors" used by Rose and Jones as part of their reason for believing that their disintegration products are ^{14}C and not some other isotope of carbon. But even on this simple picture, one huge uncertainty persists — the chance that a particle of the kind that eventually tunnels successfully through the barrier can be held, if only momentarily, to exist. What emerges from what Rose and Jones now say is that the "preformation probability" of ^{12}C would have to be comparable with that of the much simpler α-particle if it were to be produced in a distintegration. That cannot be the case, at least on this simple picture. It is relevant, but sobering, also to recall that the preformation probability of ^{14}C inferred from the results now reported is substantially greater than might have been expected from simple considerations, which is a reminder that the calculation of the absolute rates of even α decay, for example, is still not feasible.

What, in these circumstances, may be made of the discovery now reported? If, in the years ahead, there should accumulate a handful of examples of exotic kinds of radioactive decay in unstable heavy nuclei, it should at least be possible to glean some empirical information on the chance that various groups of nucleons will assemble into different potential disintegration fragments in neutron-rich heavy isotopes such as ^{223}Ra.

Hopes that exotic disintegration routes may have some practical value in other fields, perhaps in some novel technique of geochronology, seem, however, to be slim. Exotic disintegrations of the kind now identified are simply too few compared with the more familiar α disintegrations for their daughter nuclei and their products to be recognizable among the end products of the three principal radioactive series. (And ^{14}C is in any case unstable.) But at this stage it would be rash to rule out such possibilities. Too many confident predictions that new phenomena have no practical significance have too often been falsified for that course to be wise. **John Maddox**

Marine geology

Mapping the sea floor by satellite

from Roger N. Anderson

WHAT may well become one of the most famous satellites ever launched into Earth orbit transmitted for only three months before an electrical short-circuit killed it dead. Clearly, it will not go down in history as one of NASA's most successful engineering exploits. So how is it that the satellite may yet become a scientific legend?

Launched in 1978, with instruments primarily intended to map sea surface conditions, SEASAT also carried an ultra-sensitive altimeter. A continuous monitoring of the flight path of the satellite and the microwave travel time from the satellite to the sea surface and back again, allows the construction of an extremely accurate map of the topography of the sea surface. Much more than just temporal variability of the ocean surface (itself of importance) appears in such a map. For example, the map shows that the sea surface off the UK is several metres lower than the sea level off Iceland. In the Indian Ocean south of India is a huge trough — travelling from Africa eastwards towards Australia, a ship will sink over 100 m downwards and then gradually rise again. Why does this occur? Because excess mass beneath Africa and Australia pulls water away from the central Indian Ocean. Quite literally, the pull of the Earth's gravity is larger towards the edges of the Indian Ocean than at its centre. By mapping the sea surface height, one can map the Earth's gravity field since the ocean will always form a surface that is everywhere perpendicular to the direction of the gravitational pull.

If a satellite flies over a piece of ocean day after day, constantly mapping sea surface height, short-term disturbances will be averaged out and an accurate map of the Earth's gravity field can be generated. But why is such a map important?

For marine geologists the answer can be seen by considering, for example, a remote portion of the South Pacific Ocean west of the southern tip of South America and east of New Zealand (see Fig. 1). In over one hundred years of oceanographic exploration, actual depth measurements to the sea floor have been made only along the widely spaced ship tracks shown at the bottom of the figure. In only three months, SEASAT covered the same area with the satellite passes shown at the top of the figure. Obviously, if we could know how to transform gravity into bathymetry, SEASAT could make existing maps of the sea floor obsolete.

But there are military implications of such a data set too. Missile-equipped submarines, like the Trident, play a vital part in nuclear defence because they could survive a first strike. But submerged submarines must navigate. Of course, they can float radio antennae to the surface to communicate with satellites to determine their position, but how long would satellites last if a nuclear war began? Just as Cruise missiles and Backfire bombers navigate at extremely low altitudes by following the terrain of the continents, submarines could navigate relative to the terrain of the ocean floor — if they knew that topography well enough. A map from SEASAT could be as good as a road map to a submarine commander.

How then to recover the maximum amount of information from the SEASAT altimeter data? The Goddard Space Center, NOAA's National Ocean Service in Maryland, the US Navy and Jet Propulsion Laboratory in California have all had a crack at it. At low latitudes, satellite tracks are as much as 200 km apart — wider than the dimensions of geological features that SEASAT was capable of detecting. The difficulty is to preserve as much information as possible so that accurate maps of the gravity field and sea floor can be generated. Good maps were produced by these organizations (see, for example, refs 1–4), but by sacrificing details, through smoothing the data. With release of the SEASAT data to the academic community new techniques for extracting fine detail were developed. At the bottom of Figure 2 is shown existing bathymetric knowledge of an area in the southern Pacific. At the top is a gravity map produced by William F. Haxby of Lamont-Doherty Geological Observatory. The complete world-wide map is shown in reference 5.

What did Haxby do that those at other laboratories didn't? The secret is that the major geological features of the sea floor are strongly lineated as a consequence of plate tectonic processes. Trends identified in the SEASAT data were used to fill in the gaps in data coverage. The information derived from SEASAT was further enhanced by computing variations in gravitational force from a grid of sea surface heights. Think of driving slowly up a long grade to a precipitous cliff, then plunging down steeply into a valley, then up another long hill. Topography would record the gentle slope up, then the plunge down and the next slope, but the gradient of topography would record gentle slopes as virtually flat (not much change in topography from point-to-point) while cliffs show-up very dramatically because they are surrounded by a flat background, rather than by a 'real background'. Haxby went on to use north–south and east–west gradients of sea surface heights to calculate the actual gravity anomaly by combining them using La Place's equation. The map Haxby produced highlights important features of ocean topography in a way that has never before been achieved.

In the example area alone two important discoveries were made[6]. First, the clear outline of fracture zones, even under sedimentary cover, could be made out. These are scars left in oceanic plates by past plate motions and can be used to map the past movements of the Pacific and Antarctic lithospheric plates. Second, seamounts or undersea volcanoes were discovered in places where no previous seamounts were known. Chains of such volcanoes denote locales on the sea floor where extended volcanic activity has occurred long ago in the geological past. Such 'hot spot' trails not only tell of past motions between plates, but of absolute motions of the plates relative to the ultimate source of the heat, the Earth's mantle.

In the gravity map not only can we see the sigmoidal fracture zones that show gentle shifts in motion between the Antarctic and Pacific Plates over geological time, but also a north–south topographical scar left by a several hundred kilometre jump of the East Pacific Rise to the west 50 million years ago (far right, centre of image).

But there is political danger in scientific success. In October 1984, GEOSAT will be launched to map further the variability of the sea surface. But for the first 18 months of its existence, all data it transmits will be classified. The US Navy states that after 18 months of mission-oriented science, they may operate a scientific effort for the satellite, if it is still working.

In response to strong scientific interest in such satellites, from not only marine geologists, but physical oceanographers as well, there are a number of planning efforts now going forwards in the US within the Federal Agencies, the National Academy of Sciences, and in the academic community coordinated by Joint Oceanographic Institutions, Inc. The efforts are focused on the opportunities for global scientific programmes offered by the new satellite technology and on the challenges presented to all these groups in learning to work together with this new kind of data. The hope is that science will gain a respected place alongside the military in the satellite exploration of our planet — and just as important, that academic scientists will get their hands on the raw data as quickly as those from the government laboratories. □

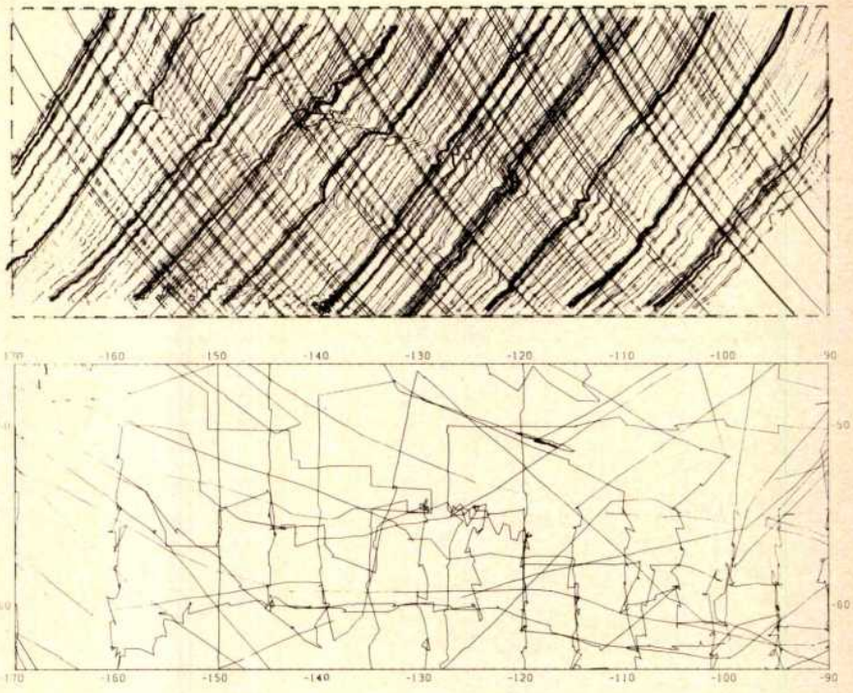

Fig.1 Top: SEASAT orbital tracks for the region of interest. Residual geoid heights are shown along descending tracks (half the total data set). Bottom: distribution of ship tracks in the region for which digital bathymetric data exist. Less than half of these cruises employed satellite navigation (from ref.6).

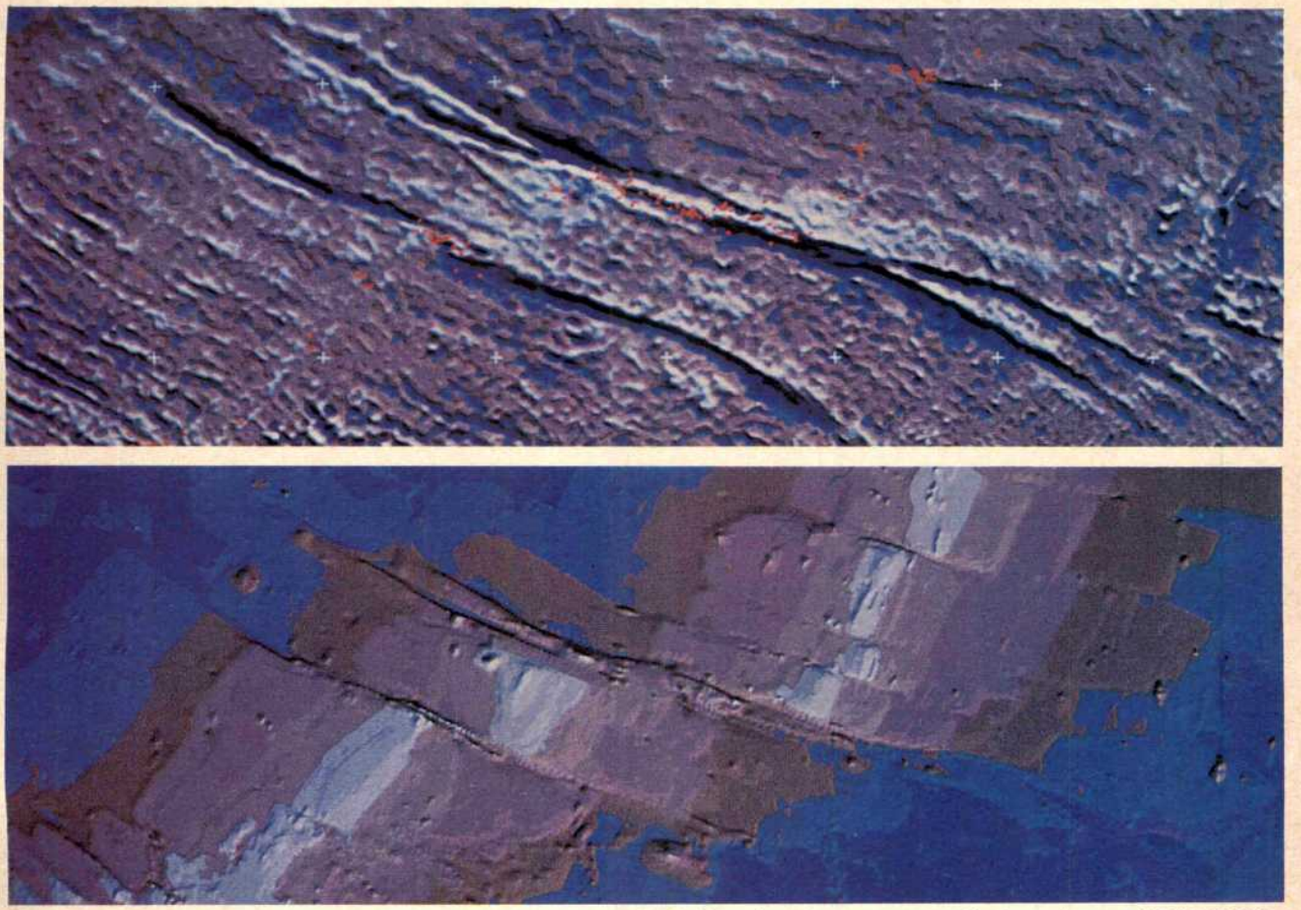

Fig.2 Top: colour relief image of gridded SEASAT-derived gravity anomalies in the region of the southern Pacific Ocean between 170°W, 90°W, 63°S and 46°S, contoured at 4 mgal intervals and illuminated from the NE. The gravity signatures of the major fracture zones (from north to south: Menard, Heezen, Tharp and Udintsev) are well defined as are several smaller fracture zones. Every 10° of latitude and longitude is denoted by a small white cross. The small red dots are epicentres of shallow earthquakes (WWSSN/NOAA sources, depths 0–70 km, $m_b > 4.5$) which occurred between 1961 and 1981. Bottom: colour image of gridded bathymetry in the same region, contoured at 500 m intervals and illuminated from the SE. The digital bathymetric data set for the Southern Hemisphere was prepared at Bay St Louis, Mississippi by scientists of the US Naval Oceanographic Office (from ref.6).

Astrophysics

The origin of gas in quasars — reverse stellar evolution?

from Martin Gaskell

WHAT is going to happen to a star situated next to the central energy source of a quasar as it is blasted by an intense stream of ultraviolet, X-ray and γ-ray radiation? A recent study by W.G. Mathews[1] makes the bold prediction that stars in such an environment will reverse the direction of their evolution!

One of the defining features of quasars is the presence of rapidly moving ($v \geq 10^4$ km s^{-1}) gas clouds with densities greater than 10^8 particles per cm^3 (much denser than normal gaseous nebulae seen around hot stars). Because they produce wide Doppler-broadened emission lines these clouds are called 'broad-line' clouds and the region from which they come is called the 'broad-line' region. From considerations of photoionization equilibrium we can work out the distance of these broad-line clouds from the central energy source (the mean ionization depends on the intensity of ionizing photons and the rate of recombinations which depends on the density). This distance is about a light year for an average quasar. In Seyfert galaxies (a kind of low-luminosity quasar) the broad-line region is expected to be an order of magnitude smaller (light-weeks to light-months) and emission-line variability observations have independently confirmed this size scale[2]. We are very confident, therefore, that the broad-line region is extremely close to the central energy source of the quasar.

The origin of the broad-line clouds is one of the major mysteries of quasars. The gas has a relatively high density, intermediate between normal gaseous nebulae and the density of the outer layers of stars[3], and a chemical composition not very dissimilar from stars such as our Sun[4], but these facts tell us very little. It is the motions of the clouds that are potentially the most important indicators of their origin. In the past all possible kinematic conditions have been given serious consideration — rotation in a disc, random orbits, infall and outflow — but it is the radiative acceleration theory that has been worked out in the greatest physical detail[5-8]. Although the issue is by no means completely settled there is mounting evidence that the broad-line clouds are indeed preferentially outflowing (rather than orbiting or infalling). For example it has been known for many years (from optical absorption lines) that ionized gas is outflowing from many high-luminosity quasars and even Seyfert galaxies[9]. Recently discovered systematic differences in broad-line profiles[10] imply that at least the highest-ionization broad-line clouds are outflowing. Perhaps the most direct evidence in favour of the radiative acceleration model is the correlation between line widths and physical conditions of broad-line clouds[11]. This is readily explicable in radiative acceleration models (since the same radiation which is accelerating the clouds is also photoionizing them) but is hard to understand in models where gravity dominates the dynamics.

Despite the growing evidence in favour of the radiative acceleration model and the unsatisfactory state of alternative gravity-dominated models[12] the problem of the actual origin of the clouds is perhaps more acute than ever. In the radiative acceleration theory a relatively steady volume source of cloud material is essential since it is only gas starting outside some critical radius which is accelerated outwards. Gas clouds created inside that radius (for example, from tidal disruption of stars near the black hole or from the accretion disc) will fall inwards (this is in fact highly desirable since one needs an influx of matter to power the quasar). The stars within a light year or so of the central energy source are the most natural source of the broad-line clouds but it has been realized for some time that normal stellar mass-loss processes (for example, stellar winds) fail by an order of magnitude or two to produce the necessary mass outflow rates if the broad-line clouds are all being expelled from the nucleus. This has led some workers to consider whether the intense radiation of quasars can itself enhance stellar mass loss. An attractive possibility is pushing the gas off the surfaces of the many lower main-sequence red dwarf stars in the galactic nuclei by the same quasar radiation pressure that will accelerate it to high velocities[13]. While this can work for red giant stars, the surface gravities of red dwarfs turn out to be prohibitively high for this sort of radiative ablation and red giants are expected to be much too rare to provide enough mass.

Mathews[1] offers a startling way out of these difficulties by proposing that red dwarf stars close to a quasar have their internal structures changed by the quasar radiation and effectively reverse their evolution by expanding. These 'inflated' stars would have lower surface gravities and could be ablated by radiation pressure. The key fact Mathews points out is that low-mass stars in the broad-line region actually have more radiant energy incident upon them than they produce by nuclear reactions or gravitational contraction. Mathews argues that if more than a few per cent of this energy can be mixed throughout the star a new configuration will be reached with an expanded star having a lower central temperature. Low-mass stars would then evolve in the opposite direction to their original contraction, towards the main sequence (hence the term 'reverse stellar evolution'). The hard X rays can deposit their energy relatively deeply in the stars and from there it can be mixed throughout the star either by convection or by large-scale meridional circulation currents (analogous to the situation in Jupiter where the incident solar radiation could do the same thing). Once the star has been inflated (or rather re-inflated) the radiative ablation process can remove matter efficiently from the surface of the star. After some 10^9 years or so the entire mass of the red dwarf star will have been removed. When the quasar has exhausted its supply of red dwarfs its activity will die down. This is in agreement with observations which show that quasars were far more active 10^{10} years ago when galaxies were young than they are now. Mathews even goes so far as to suggest that a possible deficiency of red dwarf stars in the inner one light year of our own galactic nucleus[14] could be a result of past quasar activity.

The inflation/ablation model has a number of attractive points: it gives the needed enhanced stellar mass-loss rates; the distance from the X-ray source within which stellar inflation is possible is consistent with the size of the broad-line region inferred from completely different arguments; and the gas is automatically produced at the right density and temperature. Inflated stars are also more liable to collide and produce the hot 10^8K intracloud medium. The question of whether the inflation mechanism does actually work will, however, require more detailed studies to settle it. It is certain that a star next to a quasar cannot have a normal cool 3,000K surface, but just how the harsh incident X-ray flux will affect its internal structure is a very difficult thermodynamic problem depending on poorly understood theory. If the inflation process fails and some other adequate mass-loss mechanism cannot be found then the physical model for the quasar that has emerged in recent years will need radical modification. □

Acquired immunodeficiency syndrome

The AIDS epidemic: continental drift

from Jerome E. Groopman and Paul A. Volberding

WHERE now to dig for clues to the aetiology and pathogenesis of acquired immunodeficiency syndrome (AIDS) is the major decision facing investigators this year. The study of AIDS has progressed rapidly since the initial recognition of the disorder in 1981 (ref. 1); largely through investigation of cases belonging to accessible high-risk groups such as homosexual men, intravenous drug users and haemophiliacs. The majority of those studied have resided in cities like New York, San Francisco and Los Angeles, the epicentres of the epidemic. But the cause of AIDS has not yet been identified, and digging in geographical areas outside these epicentres and investigation of atypical cases is probably going to be required.

Three types of case are now being most carefully studied: those outside the continental United States; those among persons with no known risk factors; and those that do not fit the original surveillance definition of AIDS of the Centers for Disease Control but are likely to result from the same causative agent(s).

There are currently nearly 300 cases of AIDS (defined as opportunistic infections and/or Kaposi's sarcoma in patients with unexplained cellular immunodeficiency[2]) in Europe. What distinguishes the European cases from those in North America is an intriguing link to Central Africa, particularly Zaire. Nearly all the 40 Belgian cases have had occupational or sexual contact with persons from Zaire or Chad.

A recent visit to Kinshasa, capital city of Zaire, by a team from the Centers for Disease Control and the National Institutes of Health has confirmed the existence of substantial numbers of AIDS cases in urban Zairian hospitals. Although it is still unknown whether AIDS in Central Africa predated the emergence of the disorder in the United States in the late 1970s, the occurrence of the disease outside the continental United States may provide important clues to not only its origin, but also its patterns of spread. During the past decade there appears to have been continental drift of the 'AIDS agent' among Africa, North America and Europe.

Among African cases in Africa and Europe there are about equal numbers of males and females; homosexuality does not appear to be a factor. AIDS may be transmitted among Central Africans through pathways including heterosexual sexual contact and medicinal use of unsterile needles.

The pattern of occurrence of AIDS among Haitians in the United States and in Haiti is more controversial[3,4]. There are claims that it is explicable by covert male homosexuality and that the taboos against homosexuality are so strong in Haitian society that accurate epidemiological information could not be obtained at first. It is important to resolve this controversy and to resolve it in a fashion that avoids any possible stigmatization of a socially vulnerable group like the Haitians and that does not bow to political pressures.

Studies of Central Africans and Haitians are now being carried out with special attention being paid to possible aetiological agents of AIDS. The current leading candidate is the human T-cell leukaemia virus (HTLV)[5-7]. Isolates of HTLV-like viruses have been obtained by both American and European groups from peripheral blood, lymph nodes and spleen, and molecular mapping of the isolates may point to genomic regions important in the pathogenesis of the immune suppression. Despite such endeavours, the prevalence of a number of other viruses in both Africa and the Caribbean may confound rapid identification of a unique aetiological agent.

The situation will probably be very different among persons in the US who have contracted AIDS but have experienced no known risks other than exposure to blood products. Such previously healthy persons do not have lifestyles or travel histories that particularly predispose them to infections with viruses such as cytomegalovirus, Epstein-Barr virus or HTLV. There are currently 38 cases (30 adult, 8 children) of AIDS in the United States that appear to be associated with blood transfusion.

The earliest case of transfusion-associated AIDS occurred in mid-1982 and there has been a rapid increase in cases since that time[8]. The incubation time (time from transfusion to onset of clinical symptoms) of AIDS in such cases ranges from 10 to 45 months in adults with a median of 25 months. Individuals have developed AIDS after blood transfusion with as few as two units of blood but most cases have had multiple units from several donors.

In nearly all the cases studied to date, the Centers for Disease Control was able to identify at least one donor who was 'suspicious' in that he was a member of a high-risk group for AIDS and often had associated immunological abnormalities. It is intriguing that only one 'suspicious' donor actually had AIDS as defined by the Centers for Disease Control while the others had lymphadenopathy, constitutional symptoms, or were entirely asymptomatic. This may have important implications in identifying who is capable of transmitting the disorder, at least through blood donation. There may well be an asymptomatic carrier state of the syndrome analogous to that of hepatitis B. In addition, infection with the putative AIDS agent may be transient while immune injury persists, eventually leading to clinically apparent disease. If this is true, identification of the causative agent, which may be present for only a short period of time, will require large prospective studies of individuals likely to be exposed to the agent and aggressive serial procurement of tissue.

The extraordinarily long incubation period apparent from these transfusion-related cases may be due to unknown host susceptibility factors or to a 'slow virus'. It is of note that the majority of transfusion-related AIDS cases have occurred in those regions in which AIDS is quite prevalent (New York and California) while cases among haemophiliacs does not follow the same geographical pattern. This probably relates to the fact that the factor VIII concentrates used by haemophiliacs are distributed nationwide while more standard blood products are locally distributed. AIDS has now become the second major cause of death (after haemorrhage) in haemophiliacs in the United States.

It is clear that the original surveillance definition of AIDS developed by the Centers for Disease Control was purposely narrow in scope and has excluded from the data base large numbers of individuals who probably have a milder form of the disorder. AIDS-related complex (ARC) is a constellation of clinical findings including unexplained generalized lymphadenopathy, fever of unknown origin, night sweats, weight loss and chronic diarrhoea with associated laboratory abnormalities indicating impairment of the cellular immune system. ARC is occurring in the same groups at high risk for AIDS. Data are just being accumulated on ARC patients, but it appears that their syndrome is transmissible in the same manner as AIDS and is probably caused by the same agent[9,10]. It is estimated that there are 5–10 times as many persons with ARC as AIDS in the United States, or about 15,000–30,000 cases taking CDC statistics on AIDS.

The incidence and prevalence of AIDS in certain areas of the United States is now beginning to be determined. A cohort of 6,500 homosexually active men in San

Francisco has been followed since 1978 as part of an epidemiological study of hepatitis B. The overall prevalence of AIDS in this group is one per cent and, for a subset of men 30–40 years old, nearly two per cent. The yearly incidence of AIDS in this cohort is about 0.5 per cent. This is a remarkably high incidence and prevalence for a communicable disease which is usually fatal. It can be estimated that about 5–10 per cent of this cohort may develop ARC. Should these numbers be accurate, then the United States is facing an epidemic of significant dimension and measures should be taken to contain it. □

Cell biology

Gene amplification and drug resistance

from Margaret Fox

SINCE the original reports in 1978 by Schimke and co-workers of the association of increased dihydrofolate reductase (DHFR) gene copy number with overproduction of DHFR protein and resistance to the drug methotrexate (MTX) many other examples of the association of gene amplification with drug resistance have been documented. Leading workers in the field were recently brought together at a symposium* where the major problems of the relationship between gene amplification and the development of drug resistance were discussed.

At the symposium it was made clear (G. Stark, ICRF, London and G.Wahl, Salk Institute, San Diego) that gene amplification is perhaps something of a misnomer because in almost all cases seen to date varying amounts of flanking DNA sequences are co-amplified with the selected gene to give an amplified unit which can vary from approximately 40 kilobases (kb) to over 1,000 kb in different cell lines selected for resistance to the same drug. The replacement of the term 'gene amplification' by that of 'DNA amplification' was proposed.

Most studies have been made on a variety of *in vitro* cell lines derived from human tumours, and 'normal' and transformed rodent cell lines. It is clear that if an appropriate enzyme inhibitor which binds tightly is available, then cultured cell lines will respond by amplifying the gene coding for the target protein together with varying lengths of flanking sequences. The rate and degree to which amplification occurs is directly proportional to the concentration of the inhibitor used in the case of resistance to N-(phosphonoacetyl)-L-aspartate (PALA) in BKH cells (Stark).

Data from other investigators (R. Kellems, Baylor College of Medicine, Houston and R. Wilson, Institute of Genetics, Glasgow) indicated that the level of protein overproduction was almost unlimited given sufficient selective pressure. R. Kellems, for example, reported that adenosine deaminase (ADA) levels could be increased over 10,000-fold — production then amounting to 50 per cent of total soluble protein — in cells grown in adenosine, alanosine and uridine in the presence of deoxycorfomycin. Similarly, very high levels (approximately 20 per cent of total cellular protein) of glutamine synthetase were achieved by selecting cells for resistance to the inhibitor methionine sulphoximide (Wilson). In the case of ADA, overproduction could be totally accounted for by a corresponding increase in the abundance of mRNA and ADA-coding DNA sequences which were carried on multiple double minute chromosomes.

In other drug-resistant cell lines the increase in gene copy number differed considerably, ranging from a five-copy increase associated with a very large homogeneously staining region (HSR) in a MTX-resistant HeLa cell line (J.M. Trent, University of Arizona) to the production of 600–1,200 copies of DHFR genes in EL4 mouse cells and PG19 melanoma cells (C. Bostock, Mammalian Genome Unit, Edinburgh) and a 200-fold increase in CAD sequences in PALA-resistant lines (Stark).

Sequences flanking the selected gene have always been found to be co-amplified, but the size of the co-amplified DNA varies greatly from one cell line to another. It is not clear what determines the size of the amplified unit but the co-amplified DNA sometimes expresses novel proteins which can be detected on SDS polyacrylamide gel electrophoresis. In cells selected for overproduction of adenylate deaminase (AMP.D) polypeptides other than AMP.D are overproduced (M. Debitasse-Buttin, Institute Pasteur, Paris). Analysis of several clones suggests that different polypeptides are overproduced to different extents in different clonal isolates. The implication is that the co-amplified DNA has undergone a variety of recombination events.

Overproduction of glutamine synthetase and phosphoribosyl pyrophosphate amido transferase was reported in some cell lines selected for overproduction of asparagine synthetase by the use of β-aspartyl hydroxamate and albizzin (I. Andrulis, Hospital for Sick Children, Toronto). In these resistant cell lines a good correlation was found between the level of DNA sequence amplification and abundance of mRNA and protein. Considerable differences in the levels of overproduction of asparagine synthetase achieved were observed in resistant cells selected in the two drugs. Multistep selection in albizzin resulted in 260-fold overproduction of normal enzyme but with β-aspartyl hydroxamine prolonged selection resulted in the accumulation of an apparently mutant enzyme.

In PALA-resistant clones which overproduce the CAD protein (Stark), a 45 kb sequence containing the 24 kb CAD gene was always amplified and the co-amplified DNA also coded for three other RNAs which were overproduced to different extents in different mutants. Overproduction of the multifunctional protein UMP synthetase which is inhibited by pyrazofurin and increases 40-fold in response to selection was reported by P. Suttle (University of Texas, San Antonio). These data indicate that there is not always a direct quantitative relationship between the level of gene amplification and the level of mRNA abundance.

The facility with which genes can amplify in different cell lines and the differences between cell lines with respect to whether the amplification events result in the formation of double minute chromosomes, very large homogeneously staining regions, or abnormally banding regions were much discussed. In human tumour cells and in *in vitro* cultured mouse lines, both double minute chromosomes and homogeneously staining regions have been reported, the former being generally associated with more unstable phenotypes. Amplified sequences contained in homogeneously staining regions can also be slowly lost on prolonged growth in the absence of selection (J. Biedler, Sloan-Kettering Institute, New York) but abnormally banding regions seen mostly in mouse cells appear stable. In Chinese hamster cells double minute chromosomes are rarely if ever observed. There were also suggestions of a tighter control of amplification in differentiated cells (F. Fougère Destrachette and M. Weiss, National Centre for Scientific Research, Gif-sur-Yvett).

The question of permissiveness for amplification was discussed by J.A. Wright (University of Manitoba) who reported that isolation of ribonucleotide-reductase-amplified cell lines from human diploid fibroblasts was much more difficult than from permanent rodent cell lines. Human tumour cells *in vivo* and cell lines derived from human tumour cells appear to amplify their genes with relative ease (Trent).

Several contributors addressed the

*The 18th Paterson Symposium was held at the Paterson Laboratories, Manchester, on 17–19 October 1983.

question of the structure of the amplified unit. A model involving translocation and homologous recombination was suggested by W. Flintoff (Health Sciences Center, London, Ontario); Bostock and Stark also discussed several possible models. Considerable evidence in favour of recombination being involved in the generation of amplified DHFR and CAD units was presented by both these authors. Amplified sequences have been assayed for novel fragments (joints) after differential hybridization of control and amplified DNA and subsequent cloning of amplified DNA in λ vectors. In all amplified lines novel sequences have been detected, many of which are unique to individual amplified clones. Stark posed the question as to whether selection procedures act on previously amplified sequences or whether amplification is generated by the selective agent. Data from fluctuation analysis indicated that amplification by the selective agent is of only minor importance in comparison with the action of selection on previously amplified sequences.

The question of whether genes amplify *in situ* or whether translocation and rearrangement are involved was addressed by Wahl. Cloned CAD genes of Syrian hamster were introduced into Chinese hamster cells where they can be recognized because they possess unique sequences. The donated genes were shown by *in situ* hybridization to reside on different chromosomes to the one containing the native gene and, in one case, they amplified spontaneously at a frequency at least 100-fold higher than that seen in three other transformants or wild-type cells. The suggestion is that flanking chromosomal sequences mediate the amplification event although it is conceivable that the hyper-amplifiable structure was created by the insertion of donor genes, for example, by disruption of a replication origin.

Several major questions remain unanswered. First, are normal diploid cells capable of amplifying their genes, in particular do human diploid cells possess this capacity? Human tumour cells appear to be amplification proficient, but is this an initial event in the generation of the malignant phenotype related to overall loss of genomic control or do specific alterations in DNA sequences occur followed by a cascade of events? How frequently is DNA amplification involved in intrinsic and acquired resistance in human tumours *in vivo?* Suggestions that amplification is directly involved in the generation of drug resistance come from studies of oat cell carcinoma with the c-*myc* probe in which some correlation between the presence of amplified c-*myc* sequences and refractoriness to chemotherapy was evident (Trent). Do drugs used in chemotherapy actually trigger amplification and could we prevent it if we knew the mechanism?□

Virology

Viruses and tissue injury

from Bernard N. Fields

IN A report in this week's *Nature,* Oldstone and colleagues (p.278) describe how infection of young mice with lymphocytic choriomeningitis virus leads to changes in growth and glucose regulation[1]. What is remarkable about these findings is that there is no histological evidence of tissue injury in the pituitary glands of the infected mice — even though growth hormone deficiency was clearly detectable, transplantation of growth hormone-producing cells allowed infected mice to grow normally, and the virus was shown to be replicating in the pituitary. The observation makes clear that injury as detected by conventional pathological analysis may be absent in the face of profound functional impairment and should stimulate a closer look for viruses in other diseases where the function of differentiated cells is abnormal.

The work of Oldstone and collegues is one of a number of recent reports demonstrating that viruses are capable of injuring mammalian hosts in a variety of ways not previously suspected.

Originally, it was thought that viruses were the cause of acute or occasionally chronic infections associated with detectable injury to tissues. With the development of cell culture techniques, particularly in the 1950s, viruses were detected and often identified by their characteristic cytopathic effects. The extraordinary diversity of the behaviour of viruses was further revealed by unusual or exotic occurrences such as that of subacute sclerosing panencephalitis (a progressive fatal neurological illness) occurring years after measles infection[2] and the identification of the exotic spongiform encephalopathies (such as Kuru of man and scrapie of sheep) in which a progressive degenerative neurological illness occurs without fever or an inflammatory reaction and is due to a transmissible agent that has a number of extraordinary properties (possibly including the absence of nucleic acids)[3]. Recent studies using animal models have expanded further the possible role of viruses in diseases of unknown aetiology and illustrated new ways that viral injury may be mediated. It is now clear from experiments in mice that viruses can specifically injure endocrine tissue, leading to abnormalities of endocrine secretions[4], and the work reported in this issue shows that lymphocytic choriomeningitis virus can alter pituitary cells, causing them to produce hormonal deficiences, while producing no detectable cytopathic effects[5].

It is especially interesting that the findings with lymphocytic choriomeningitis virus demonstrate how endocrine tissue may be affected since viral infections have long been considered as leading candidates in the causation of insulin-dependent diabetes mellitis[6]. While there are a number of important differences between insulin-dependent diabetes mellitus and the lymphocytic choriomeningitis disease described by Oldstone and colleagues (particularly the presence of tissue injury as manifested by insulitis in the former), insulin-dependent diabetes mellitus serves to illustrate additional ways by which virus infections may result in disease. In particular, the studies of Notkins and co-workers have shown that certain viruses may directly infect pancreatic β cells in mice resulting in chemical diabetes[7]. Viral infections of mice may also result in autoantibodies to growth hormone and a polyendocrinopathy[4]. While the relevance of these mouse models to human illness has not been proven, it is clear that antihormone antibodies and antitissue antibodies are additional important ways that viral injury may be mediated.

Evidence for another route by which virus infection may lead to the production of autoantibodies and tissue destruction has been seen in recent studies of the mammalian reoviruses[8]. Viral receptors were postulated to share structural features (idiotypes) with antibodies directed against the viral haemagglutinin (the protein of the virus responsible for attachment to the cell). Anti-idiotypic antibodies directed against antibodies to the reovirus haemagglutinin could thus bind to cell surface receptors on uninfected host cells in a manner resembling the virus and could destroy cells bearing complimentary receptors. Interestingly, cytotoxic T lymphocytes generated after reovirus infection have been shown to be capable of lysing uninfected B-lymphocyte cells bearing anti-idiotype-like structures on the cell surface[9].

The slow virus infections are among the most interesting and least understood of all infectious diseases[2]. This class of diseases, of which scrapie disease of sheep is one example, is characterized by long incubation periods, a progressive degenerative neurological illness and an unusual agent (termed 'prions' by Prusiner and colleagues[10]). Partially purified preparations of the scrapie agent contain a 'prion' protein (designated PrP) that is unique to scrapie preparations and may be a structural component of the prion[5]. Insight into the nature of the injury caused by scrapie may come from the observation that prion preparations contain numerous rod-shaped particles that, like amyloid, exhibit a green colour and birefringence by

© 1984 Macmillan Journals Ltd

polarization microscopy. As pointed out by Prusiner and colleagues, amyloid deposits have been seen in a number of degenerative disorders of the central nervous system. A direct link between the putative rods associated with scrapie and amyloid would provide a major clue to the aetiology of a number of degenerative diseases. Unfortunately, the association between prions and amyloid is not yet certain as normal cells contain rod-like structures, and 'prions' have not yet been completely purified[5].

Clearly, the means by which viruses can injure their hosts are diverse. These include injury due to subtle effects on cell metabolism without overt pathological change, the production of autoantibodies to tissue components or products, and the deposition of material related to normal cell products. What remains to be determined is which of these strategies of virus-induced injury are important in causing human disease. □

Natural materials

Chalky submarines

from Paul D. Calvert

MOST of us, if asked to design a submarine, would not think of chalk as a very suitable constructional material. But a recent paper by Birchall and Thomas (*J. Materials Sci.* **18**, 2081; 1983) on the structure of cuttlefish bone illustrates how good design can procure impressive performances from the most unpromising starting materials.

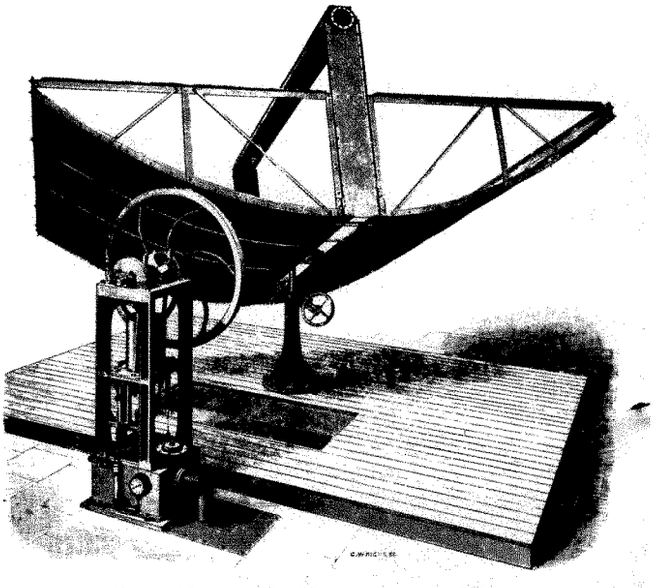
The cuttlefish (*Sepia officinalis*, a relative of the squid) maintains neutral buoyancy at varying depths in the sea by pumping water into or out of the cuttlebone which is divided into small closed compartments. When empty of fluid these cells are at a pressure of about 0.8 atmospheres. Hence they must withstand a high external hydrostatic pressure corresponding to the depth of the fish (1atm per 10 m).

The cuttlebone structure comprises parallel sheets of calcium carbonate (aragonite) about 10 μm thick separated by 200–600 μm. The sheets are held apart by pillars after the manner of a multistorey car park except that each layer is sealed from those above and below. The whole assembly is supported on a 1.5 mm dense bony dorsal shield.

The obvious design for a pressure-resistant vessel is a thick-walled hollow sphere — just as seen in a bathysphere. A simple calculation for a given compressive strength of the material would give this sphere a density of about 75 per cent of either a layered pillared structure or a cylinder. Birchall and Thomas measure the same crushing strength perpendicular or parallel to the layers as the structure has to resist uniform hydrostatic forces. Apparently, the cuttlefish trades the improved depth resistance that would come from a spherical pressure vessel for an elongated cuttlebone which can also act as an internal skeleton. The pillared layer structure bears a strong resemblance to the skin-and-honeycomb panels used to obtain maximum rigidity with minimum weight in aircraft and provides a light and rigid skeleton for the cuttlefish.

A problem with using such an intrinsically brittle material as chalk is that it can be quite strong in compression but relatively small tensile loads can produce failure. Much of the design of the medieval cathedrals can be seen as an exercise in minimising or eliminating tensile loads, but the cathedrals did not have to swim around and fight. One way of circumventing the problem is to ensure that local failure does not lead to catastrophic collapse. Crushing tests show that the cuttlebone does fail by a progressive collapse of the layers rather than imploding as would a hollow structure.

The cuttlefish would also like to get as much tensile strength from the material as possible without sacrificing compressive strength or rigidity. This is also very much a concern in the production of synthetic ceramics both in the context of 'high performance' ceramics, which are the subject of a recent Japanese initiative (*Nature* **305**, 373; 1983), and in the high-strength cements developed by Birchall and his co-workers (*Nature* **289**, 388; 1983). For maximum strength one would like a fine grain size; very small pores, if any; and strong bonds between the grains. The key to the high strength of biological ceramics is their four per cent organic component — a protein–chitin complex which forms a layer covering the carbonate surface. The organic component acts as a nucleating surface for the aragonite crystals and may play a more important part in preventing the crystals from growing too large and/or in improving the bonding between the crystals. S.A. Wainwright and co-authors discussed these ideas well in *Mechanical Design in Organisms* (1976).



The operating parameters for a cuttlefish seem quite respectable when compared with submarines. The cuttlebone crushes at pressures corresponding to a depth of about 230 m and cuttlefish have been recorded at depths of 200 m. The osmotic pump which controls the gas–fluid exchange in the bone would not work beyond about 240 m. By comparison large submarines are reputed to be limited to operating depths of 300 m, which is only about twice their own length, despite being constructed of far stronger materials. It seems almost sacrilegious that such a sophisticated structure as cuttlebone should frequently end up as a budgerigar's beak cleaner! □

100 years ago

THE SUN MOTOR

THE illustration represents a perspective view of a sun motor put in operation last summer. The leading feature of the sun motor is that of concentrating the sun's radiant heat by means of a rectangular trough having a curved bottom lined on the inside with polished plates so arranged that they reflect the sun's rays towards a cylindrical heater placed longitudinally above the trough. This heater contains the acting medium, steam or air, employed to transfer the solar energy to the motor; the transfer being effected by means of cylinders provided with pistons and valves resembling those of motive engines of the ordinary type.

Observation of stellar remnants from recent supernovae

David J. Helfand

Columbia Astrophysics Laboratory, Departments of Astronomy and Physics, Columbia University, New York, New York 10027, USA

Robert H. Becker

Department of Physics, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061, USA

The current observational situation regarding the presence or absence of collapsed stellar objects associated with supernova remnants is reviewed. The theoretical expectations and observational evidence for the various possible classes of stellar remnants are discussed. The results of searches for these objects in the radio, optical, X-ray and γ-ray regions of the spectrum are outlined with the conclusion that nine bona fide *candidates are currently known. The implications of these results for the origin and evolution of compact objects are summarized.*

FIFTY years ago Baade and Zwicky[1] established the distinction between common novae and the vastly more energetic supernovae which they argued must bear visible witness to the destruction of a normal star. They also concluded[2] "With all reserve, we advance the view that a supernova represents the transition of an ordinary star into a neutron star.... Such a star may possess a very small radius and an extremely high density". Eight years later, Baade[3] and Minkowski[4] discussed the Crab Nebula as the remnant of the supernova reported by the Chinese in AD 1054, and pinpointed the central star as the compact object powering the Nebula's emission. In Minkowski's words, "Taken altogether, the spectroscopic evidence admits, but does not prove, the conclusion that the south preceding star is the central (exciting) star of the nebula". He went on to place an upper limit on the size of the star of $<0.02\,R_\odot$.

Theoretical work on the final state of collapsed stellar cores continued over the next three decades, although the observational picture remained static. Then, at the end of the 1960s, the suggestions of Baade and Zwicky were dramatically confirmed with the discovery in rapid succession of radio pulsars[5] (isolated neutron stars), X-ray pulsars[6] (accreting-binary neutron stars) and Cygnus X-1 (ref. 7) (presumably an accreting black hole). As the change in gravitational energy for a star between its normal state ($R \sim 10^{11}$ cm) and one of these collapsed configurations ($R \leqslant 10^6$ cm) is $\sim 10^{53}$ erg, the formation of compact objects must be accompanied by a huge release of energy. The explosion itself is, in at least some cases, visible as an optical supernova, while the small fraction of the energy which couples to the surrounding medium leads to an expanding bubble of shock-heated material, compressed magnetic fields and relativistic particles which we observe at later times as a supernova remnant (SNR).

The modern theory of supernova explosions admits several possibilities regarding the fate of the stellar core. Leventhal and McCall[8] originally suggested that a remnant white dwarf might be required to explain the late time light curve of Type I supernovae (SN). While this explanation is no longer thought to be relevant, SN explosion models have recently been constructed in which a core of $\sim 1\,M_\odot$ supported electron degeneracy remains following the ejection of the star's outer layers[9]. The standard models for more massive stars[10] require a central implosion which pushes the electron degenerate pre-supernova core to densities of $\geqslant 10^{14}$ g cm^{-3} and results in the formation of a neutron star. In very massive stars, the neutron degeneracy pressure of this phase may be insufficient to halt the collapse and a black hole will form. Finally, in some instances such as the carbon detonation[11] and pair instability[12] scenarios appropriate for stars in the 4–8 $M_\odot$ and 100–300 $M_\odot$ mass ranges, respectively, the core may disrupt completely along with the rest of the star and no stellar remnant is formed. The applicability of these various models to a specific mass range and evolutionary history of SN progenitors is still quite uncertain. Likewise, the properties of the stellar remnants themselves—mass, surface temperature, magnetic field strength and angular momentum—are not well-determined by the theories and we must look to observations of the sites of relatively recent SN explosions to delimit the range of possibilities.

As noted above, a blue star with a peculiar spectrum in the 1,000-yr-old Crab Nebula was the first suggested candidate for the compact remnant of a SN explosion. This suggestion was confirmed 35 yr after it was first made with the discovery that this star was a radio[13,14] and optical[15] pulsar: a rapidly rotating ($\Omega \sim 200$ rad s^{-1}), magnetized ($B \sim 10^{12}$ G) neutron star. This discovery actually followed by a few weeks the detection of a similar object in the 10^4-yr-old Vela SNR[16]. Despite numerous searches in various wavelength bands throughout the electromagnetic spectrum, however, no further pulsar/SNR associations were discovered between 1969 and 1979, although the circumstantial evidence that a significant fraction of SN must produce neutron stars became compelling. Several hundred more slowly rotating (and presumably older) radio pulsars were discovered, suggesting $\geqslant 10^5$ such objects existed in the Galaxy and leading to a pulsar birth rate currently estimated as 1 per 40 yr (ref. 17). In addition, 100 of the brightest galactic X-ray sources were found to be binary systems powered by accretion of matter from a normal companion onto an orbiting neutron star or, in perhaps a few cases, a black hole. Neutron stars were also implicated in other discoveries of the decade including 100 MeV γ-ray sources, globular cluster X-ray sources, and γ-ray and X-ray bursters. Integrating a 1 per 40 yr birthrate over the lifetime of the Galaxy, a total galactic population of $\sim 5 \times 10^8$ neutron stars seemed probable.

Comparison of these population statistics with the rate of SN occurrence in the Galaxy (variously estimated as 1 per 20 yr from comparison with the rates observed in external galaxies[18] to 1 per 80 yr from the SNR formation rate[19]) suggests that either most SN produce compact stellar remnants or that such collapsed objects can be formed in some less spectacular manner. However, even if all SN do result in the formation of a stellar remnant, there is good reason to doubt that they all result in the formation of a rapidly rotating magnetized neutron star similar to the Crab pulsar. The radio, optical, and X-ray appearance of the Crab Nebula is clearly different from that of most other historical SNR. Its centrally peaked brightness distribution, flat radio spectrum and high degree of linear polarization are understood to result from the injection of relativistic parti-

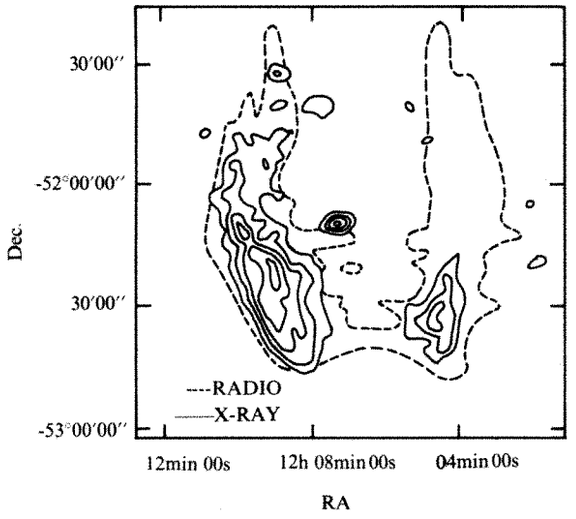

Fig. 1 A radio/X-ray contour plot of the remnant PKS1209−52.

cles accelerated near the neutron star; that is, the presence of the Crab pulsar could have been inferred from the surrounding synchrotron nebula even if the pulsed radiation had gone undetected. Most other historical SNRs show neither a pulsar nor any evidence for pulsar accelerated particles. From this one must conclude that either most SN do not create rotating magnetized neutron stars or that they create such stars in an environment or with characteristics which suppress the formation of a synchrotron nebula.

Examples of this second possibility, that neutron stars exist in SNRs but cannot accelerate particles, include a close binary system with mass transfer, in which the pulsar mechanism is smothered, and a stellar magnetic field outside some allowed range within which the pulsar mechanism operates[20,21]. We know that neutron stars do occur in binary systems from observations of X-ray pulsars but, until recently, none was known to be associated with a SNR; two have now been found[22,23]. The idea that some newly-formed neutron stars may suffer from an intrinsic inability to produce high energy particles is a relatively new one and no clear cases have been confirmed, although the possibility that such stars have been detected through their surface thermal emission is not excluded (see below). Within this context, then, we outline below the current status of the continuing search for the stellar remnants of supernovae.

Searches for compact remnants

Radio: The association of radio pulsars with SNRs has rested on the two cases of the Crab and Vela for over a decade, despite the discovery of over 330 other pulsars and the cataloguing of over 140 SNR. The fact that there are no other coincidences is a cause for concern but not, perhaps, alarm. Several observational selection effects work against the discovery of young pulsar/SNR pairs in most pulsar searches: decreased receiver sensitivity resulting from the added noise of the remnant itself, decreased search sensitivity at short periods, the increased severity of pulse smearing for short-period sources due to large dispersion measures and multipath scattering, the large distances to most SNR (50% of the known pulsars are <2.3 kpc away, whereas only ~10% of the SNR are within this distance), and the fact that perhaps as few as 1 in 5 of the pulsars will have beams which intersect our line of sight. High pulsar proper motions are not a problem, as the mean expansion velocity of even a 20,000-yr-old remnant is $\geq 400\ km\ s^{-1}$, larger than the largest measured pulsar transverse velocities.

A few targeted searches have been conducted on several nearby SNR. Manchester and Taylor[24] catalogue the results through 1976 for 12 remnants ranging in distance from 2 to 10 kpc. The limits are in the range $L_R \sim 5\text{–}10 \times 10^{25}\ erg\ s^{-1}$, only a few times that of the weakest known pulsar and a factor $>10^3$ less than the radio luminosity of the Crab. More recently, Seiradakis and Graham[25] have searched 20 SNR within 8 kpc to a similar sensitivity at 21 cm in an attempt to limit the problems of the SNR background and pulse smearing. However, their lower limit to periods was 300 ms and no new sources were found. Manchester *et al.*[26] have just completed a larger 21-cm search in the Southern Hemisphere covering 55 galactic SNR, 30 Large Magellanic Cloud (LMC) remnants, and several other objects, including two Cos B γ-ray sources. At a limiting sensitivity of 1 mJy out to dispersion measures of 1,800 cm^{-3} pc, they detected three new galactic pulsars only one of which[27] is clearly associated with a SNR—the recently identified X-ray pulsar in MSH15-52.

We need not assume, *a priori*, that all compact sources within SNR will be radio pulsars. In 1973, a variable unresolved, radio source named CL4 was discovered near the centre of the Cygnus Loop[28]. The source was immediately discussed as a possible stellar remnant, although it was also argued that it was extragalactic[29]. Very recently, CL4 was identified as a background quasar[30]. In 1978, a list of nine unresolved radio sources, all located within SNR, were proposed as candidate stellar remnants[31]. The list included two sources previously detected as X-ray objects, SS433 and Cir X-1, as well as CL4. It is now well known that SS433 is associated with the SNR W50 (ref. 22). Cir X-1 is without doubt also a galactic object, but its association with G321.9−03 has never been firmly established. Recent reviews summarizing the remaining sources in the list suggest that the others are all unrelated background objects[30,32]. Thus, the Crab and Vela pulsars, along with SS433, remained until very recently, the only radio-emitting stellar objects associated with SNR.

Optical: Hind and Plummer[33] were perhaps the first to suggest a specific object as the compact remnant of a supernova explosion: an 11th magnitude variable star near the position of Tycho's SN. Baade[3] and Minkowski[4] were the first to identify such an object correctly when they pointed to the 'south-preceding' star near the centre of the Crab Nebula as the stellar remnant of SN1054. Over the next 40 yr, the search continued for 'peculiar' optical objects in the historical remnants and a variety of candidates have been reported, none of which is now thought to be relevant. The most recent such search reviews many of these early attempts but finds no convincing new candidates[34]. Following the discovery of optical pulses from the Crab in 1969, several searches of both galactic and extragalactic SNR using fast photometry were conducted. Horowitz *et al.*[35] set limits ~5 mag fainter than the Crab for any short-period pulsed sources near the centre of Kepler, Tycho, Cas A and 3C58. Papaliolios *et al.*[36] conducted a similar search at the sites of 31 recent extragalactic SN without success. More recently, Pennypacker[37] has extended the search into the IR (0.9–2.4 μm) to take advantage of lower interstellar extinction; he obtained pulsed IR limits 3–4 mag fainter than the Crab for the remnants studied in ref. 35.

In 1980, an optical search of the remnant of SN1006 resulted in the discovery of a hot blue star ~2.5 arc min from its centre[38]. Subsequent observations identified the object as one of only five known sub-dwarf OB stars[39]. The offset between the stellar position and the remnant centre would require an extremely high transverse velocity ($800\ km\ s^{-1}$) for the star, seemingly violating the current proper motion limit for this object[38]. Recently, very broad symmetric absorption lines have been detected in the UV spectrum of this object, confirming that it is an unrelated background star lying behind the remnant[40].

There are thus only three optical point sources associated with the remnants of SN: the Crab and Vela pulsars and SS433. Incoherent synchrotron emission in the outer magnetosphere is thought to be responsible for the pulsar light curves[41] and is expected to scale with the neutron star rotation period P as P^{-10} (ref. 42). Thus, sources with $P > 50$ ms will have $m_v > 20$ for distances of 1 kpc, and are unlikely to be detected even if

p = Limit or detection based on pulsed flux only. Column (2), best available positions for point sources of radiation. Column (3), distances to SNR from reference quoted in column (9); if a range is given, the mean value has been adopted. Column (4), unless quoted directly from the reference cited in columns (9)(5b), the X-ray luminosity in the 0.2–4.0 keV band has been calculated from L_x = IPC rate (5b) $\times 5\times10^{-11}$ erg [cm^2 counts s^{-1}]$^{-1}\times\exp[D_{kpc}/10]\times4\pi D^2$ (column (3)), appropriate for sources at distances $D\geq1$ kpc with a Crab-like spectrum modified by interstellar absorption in a medium of mean density of 1 cm^{-3}. Column (5a), Mean diameters in arc min taken from refs in column (9). b, Einstein imaging proportional counter rates taken from refs in column (9); an *H* following the rate indicates that it was derived from a high resolution imager counting rate and multiplied by a factor of 5, the mean IPC/HRI ratio. c, The number of sources expected *a priori* above the flux in column (5b) within an area the size of the SNR in question, calculated from the expression in the text; a *c* following the expected value indicates that the source is centrally located in the remnant, reducing the probability of chance superposition still further. Column (6), unless quoted directly from the ref. cited in column (9) the radio luminosity has been calculated from $L_R = 4\times10^{27} f_{mJy}\times D^2_{kpc}$ appropriate to a ν^{-1} spectrum integrated over a bandwidth of 3×10^9 Hz. Column (7), unless quoted directly from the ref. cited in column (9) the optical luminosity has been calculated from $L_{opt} = 2.4\times10^{-6}\times10^{-(2m_v - D_{kpc})/5)}\times4\pi D^2$, where m_v is the visual magnitude of the source or the upper limit to the X-ray source counterpart, and an extinction of 1 mag kpc^{-1} has been adopted. Column (8) γ-ray limits calculated using $f[E>100\,\text{MeV}] = 1\times10^{-6}$ photons cm^{-2} s$^{-1}\times4\pi D^2 = 10^{34}\times D^2_{kpc}$ erg s^{-1}; in the cases of RCW103 and W28, fluxes of the nearby γ-ray sources CG333+1 and CG006−0, respectively, have been substituted for the Cos *B* galactic plane survey limit of $\sim1\times10^{-6}$ photons cm^{-2} s^{-1}. Column (9), TW, this work (data published here for the first time). PC, Personal communication from J. Kriss.

their beams are pointed in our direction. If neutron stars are born with very short periods ($P\leq5$ ms) and this scaling holds, however, they could be visible at distances up to 100 Mpc. A source such as SS433 would be visible in any remnant in the nearer half of the Galaxy. Although it would be instantly recognizable at high spectral resolution, its colours are not unusual and similar objects could have escaped detection.

X ray: The launch of the Einstein Observatory with its complement of two X-ray imaging detectors[43] provided a new and powerful tool for the detection of weak cosmic X-ray sources. The high spatial resolution not only increased our sensitivity by several orders of magnitude but also allowed us to discern the presence of point-like sources of emission within extended objects (particularly applicable to SNR). Before 1979, X-ray emission had been detected from the vicinity of all three known stellar remnants within SNR. Images taken with Einstein resulted in the detection of nine additional stellar remnant candidates which are listed in Table 1 along with the original three. Of all these sources, only the objects within the Crab Nebula[44], G109.1−1.0 (ref. 23), and MSH15−52 (ref. 45), have been observed to pulse in X rays, although the upper limit on pulsations in the other objects is restrictive only for the Vela pulsar. This lack of detected pulses leaves room for some uncertainty in the emission mechanism involved; possibilities include blackbody radiation from the stellar remnant's surface, nonthermal emission from the magnetosphere (as is the case for the Crab pulsar), or accretion from a companion star (as is likely for the G109.1−1.0 source)[46]. Unfortunately, most of these sources are quite weak (≤0.01 μJy at 1 keV), and it is unlikely that another opportunity to study them will arise for several years to come.

Despite the success of Einstein in tripling the number of compact sources associated with SNR, it is still true that most remnants contain no point source of electromagnetic radiation. The seven historical remnants (Cas A[47], Kepler[48], Tycho[49], Crab[50], SN1006 (ref. 51), 3C58 (ref. 52) and RCW 86 (ref. 53)) have been particularly well studied, and only the two Crab-like remnants (the Crab and 3C58) show point source emission. In addition, the Einstein programme[54] included 65 other galactic remnants as well as at least 31 confirmed SNR in the Magellanic Clouds[55]. Three of the 25 LMC remnants have centrally-condensed brightness distributions with at least two of the three exhibiting power law X-ray spectra[56]. Limited instrumental resolution does not permit us to resolve any point source components in these objects, but their presence may be inferred by analogy with the galactic Crab-like remnants. None of the other remnants in the Large or Small Clouds shows any signs of an associated point source. In the Galaxy, seven additional Crab-like remants were observed: point sources were detected in two of them (Vela[57] and CTB 80 (ref. 52)), two more were detected as X-ray emitters but no point sources were resolved (G21.5−0.9 (ref. 58) and G29.7+0.3 (ref. 59)), and three were too distant to detect at all. Of the 58 shell-type remnants studied (33 of which are within 5 kpc), point sources have been reported within the boundaries of eight. However, these remnants cover a large area of sky and the number of chance coincidences with foreground (stars) or background (active galactic nuclei) interlopers is non-negligible. Table 1 lists the number of sources at or above the observed flux, *S*, to be expected within the boundaries of each remnant calculated from the known surface density *N* of soft X-ray sources[60].

$$N(>S) = 6.5\times10^{-4}\left(\frac{S}{1\ \text{IPC cts s}^{-1}}\right)^{-3/2}\ \text{sources deg}^{-2}$$

where a conversion factor of 2.5×10^{-11} erg cm^{-2} s^{-1} per IPC count has been assumed. (IPC is the imaging proportional counter on the Einstein Observatory, see ref. 43.) Three sources have a rather high probability of being chance superpositions: W28, PKS1209−52 and G127.1+0.5. The latter source is already known to be the serendipitous alignment of a radio galaxy at redshift $z=0.018$ with the remnant's centre[61,62] (however, see ref. 63 for an alternative view of this object); the sources in W28 and PKS1209−52 (Fig. 1) are significantly offset from the remnant centres. Eliminating the three large nearby remnants which span several square degrees each (Monoceres, Lupus and the Cygnus Loop), we calculate the expected number

Table 2 Sample upper limits on compact objects in SNR

p, Limit based on pulsed flux only.

* Assuming (1) a limit on pulsed flux at 400 MHz of 10 mJy, consistent with the sensitivity of recent all-sky pulsar surveys, and (2) a limit of 50 mJy at 1,400 MHz for a radio-point source associated with any SNR and as yet unnoticed.

† Assuming a limit of 0.02 IPC count s^{-1} for a point source associated with any SNR surveyed with the Einstein Observatory and as yet unnoticed.

‡ For comparison with the Crab and Vela pulsed 400 MHz fluxes, we have used pulsed flux limits from the cited references and computed the distance-corrected ratio for the pulsed luminosity limits (denoted by *p*); for comparison with SS433 at 1,400 MHz, we have used limits derived from the 1,400 MHz maps cited and computed the distance-corrected ratio for the luminosity limit. Distances of 3.0 kpc and 1.0 kpc were adopted for Cas A and SN1006, respectively.

§ Optical luminosities were calculated as in Table 1 from magnitude limits in the cited references and compared with those quoted in Table 1 (column (7)) for the Crab, Vela and SS433.

‖ X-ray luminosities were calculated as in Table 1 from IPC (or HRI × 5) count rate limits in the cited references and compared with those from column (4) in Table 1.

¶ γ-ray luminosities were calculated as in Table 1 from the Cos B galactic plane survey limit in the quoted reference and compared with those from column (8) in Table 1.

of chance coincidences for the sample of 60 shell-type remnants as a whole is ~4, in reasonable agreement with the three probably spurious associations found.

The results of the X-ray survey, then, are that point sources are associated with at least 4 of the 9 Crab-like remnants and at most 5 of the 63 shell-like remnants (5 of 30 within 5 kpc where the survey is complete to a limiting luminosity of $\sim 2 \times 10^{33}$ erg s^{-1}). The completeness of our sample for the various types of point source emitters is discussed below.

γ-ray: The Crab and Vela pulsars were both detected in the first survey of the sky at energies >50 MeV (refs 64, 65). The most recent catalogue[66] of localized γ-ray sources from the COS B survey contains 25 entries; the Vela pulsar is the brightest source in the sky in the 0.1–3.0 GeV band and, along with the Crab, is one of only four sources identified with objects known in other spectral regimes. Both sources have also occasionally been reported as detections by ground-based Cerenkov air shower experiments operating at photon energies $>10^{11}$ eV (ref. 67). Despite earlier reports to the contrary, these are the only two radio pulsars that have been detected above 2 keV, although several workers[68–70] have suggested that young pulsars form a significant component of the unidentified γ-ray source population.

The whole galactic plane (and, therefore, most galactic SNR) has been covered in the COS B survey to a limiting flux of $\sim 1 \times 10^{-6}$ photons cm^{-2} s^{-1} ($E > 100$ MeV)[66]. For a source with a Crab-like spectrum at a distance of 1 kpc, this corresponds to a γ-ray luminosity of $\sim 10^{34}$ erg s^{-1} (5% that of the Crab pulsar). We could thus detect any Crab-like source within 4–5 kpc. A semi-empirical prediction of the pulsed γ-ray luminosity from a pulsar magnetosphere is given by L_γ (>100 MeV) ~ $2 \times 10^{32} B_{12} P^{-1.7}$, where B_{12} is the pulsar surface magnetic field in units of 10^{12} G and P is the pulsar period[71]. Thus, even sources with periods as long as 0.1 s may be detectable out to 5 kpc. Without *a priori* knowledge of the period, however, the counting statistics of the γ-ray maps are too poor to establish the pulsed nature of such sources.

In fact, roughly a quarter of the known localized γ-ray sources are, within their large error circles (diameter ~1–2°), positionally coincident with catalogued radio SNR[72,73], a result of marginal statistical significance. Lamb and Markert[74] have examined three of the associated remnants at soft X-ray energies with Einstein and find nothing unusual in any of them. Further progress must await new γ-ray observations with improved angular resolution and sensitivity. Observations at these energies offer a unique window on young pulsars as the γ rays may be produced in a fan beam visible to all observers[75], unlike the narrow pencil beams dominant at lower energies. The very different pulse profiles of Vela at radio and γ-ray wavelengths and the pulse–interpulse morphology of both the Crab and the Vela at high energies suggest that the γ-radiation arises from farther out in the magnetosphere than does the radio emission and thus is likely to have a substantially wider beamwidth. It has been argued that 'Geminga', the brightest unidentified γ-ray source which has a soft X-ray counterpart but no detectable radio emission, is an example of such a γ-ray pulsar whose radio beam is pointed away from us (D.J.H., unpublished data).

We consider the first nine objects listed in Table 1 as highly probable associations of SNR and radiating compact stellar remnants. All are detectable in the soft X-ray band, four are radio sources, three have optical counterparts and two are seen at γ-ray energies. We discuss below the source classes and evolutionary state of these objects; here we summarize the current upper limits to similar sources of radiation in other galactic SNR.

In Table 2 we list, for various spectral regimes, the upper limits on point source emission in several SNR: the youngest (~325 yr) known remnant Cas A, the closest (~1 kpc) historical remnant SN1006, and a typical remnant at a distance of 5 kpc. The limits are quoted as fractions of the luminosity of the Crab, a 10^3-yr-old radio pulsar; of Vela, a 10^4-yr-old radio pulsar, and of SS433, a system which is, to date, observationally unique, but which probably contains an accreting neutron star or black hole.

Perusal of Table 2 leads to a number of interesting conclusions. One can now assert that a pulsar similar to that in the Crab Nebula is not present in any of the nearby SNR. This conclusion holds independent of the radio beaming pattern for two reasons: (1) the theoretical and phenomenological arguments presented above which suggest that pulsed γ rays are radiated in a wide beam visible to most observers; and (2) X-ray synchrotron nebulae similar to the Crab Nebula have now been found surrounding all three young radio pulsars (Crab[76], Vela[57], and MSH15−52 (ref. 45)), as well as around several older isolated pulsars[77,78]. The soft X-ray luminosities of these nebulae are comparable with or greater than the pulsed radiation and would be easily visible within any of the shell-type remnants out to 5 kpc.

A pulsar similar to Vela would also not have escaped detection in any of the well-studied remnants, although a distance of 5 kpc is about the limit to which the various surveys would have detected such an object. Thus, we can conclude that an active radio pulsar born in any of the 36 closest SNR must be radically different from our two canonical young pulsars (for example, $P > 0.1$ s at birth, and a very low magnetic field strength).

Table 3 Supernova scenarios for binary stars

Case	Primary mass ($M_\odot$)	Companion mass ($M_\odot$)	Resulting system*	Observational consequence
I	>10	>10	(a) SN+>10	Visible: wind-powered binary
			(b) SN+>10	Visible: wind-powered binary
II	>10	4–10	(a) SN+>10	Visible: wind-powered binary
			(b) SN+4–10	Visible: wind-powered binary
III	>10	<4	(a) SN+4–10	Visible: wind-powered binary
			(b) SN+>4	Disrupts
IV	4–10	4–10	(a) SN+>10	Visible: wind-powered binary
			(b) SN+4–10	Visible: wind-powered binary
V	4–10	<4	(a) SN+4–10	Visible: wind-powered binary
			(b) SN+<4	Disrupts
VI	<4	<4	(a, b) WD+<4 → SN+evolved star	Visible: Roch-lobe overflow binary

* Case (a) represents conservative evolution wherein most of the material lost by the primary is transferred to the companion whereas in case (b) most of the mass lost by the primary leaves the system. In more realistic treatments of nonconservative mass transfer, the companion star often still accretes sufficient material to reverse the mass ratio of the system and prevent disruption of the binary in the SN event. Thus, low-mass, Roche-overflow driven binary such as Her X-1 can result from a progenitor system with initial masses greater than in case VI (ref. 131).

An SS433-type object with $L \geq 10^{-2}$ of the X-ray or radio luminosity of the prototype is also unlikely to have escaped detection in any SNR out to at least 5 kpc. Likewise, a less spectacular accretion-powered X-ray source such as that in G109.1−1.0 would also be easily visible to that distance in the X-ray band. In fact, for any compact remnant that remains in a binary system, our X-ray survey luminosity limit of $L_X \leq 2\times10^{33}$ erg s^{-1} allows us to limit the mass loss rate $\dot{M}$ of its companion star as:

$$\dot{M} < 3\times10^{-11}\, M_\odot\, \mathrm{yr}^{-1}\left(\frac{\zeta}{0.1}\right)^{-1}\left(\frac{M_x}{1.4M_\theta}\right)^{-2}\left(\frac{a}{10R_0}\right)^{2} \times\left(\frac{v_w}{500\ \mathrm{km\ s^{-1}}}\right)^{4}\left(\frac{D}{1\ \mathrm{kpc}}\right)^{2}$$

where ζ is the fraction of the rest mass energy of accreted matter that is converted to radiation, v_x is the mass of the collapsed object, a is the orbit semimajor axis and v_w is the velocity of the stellar wind[79]. Thus, the main-sequence companions of any such putative close binaries are rather weakly limited by the X-ray survey to those with mass loss rates typical of spectral types later than A5 ($m_v > 7$) for 1 kpc and later than B5 for 5 kpc ($m_v > 12.5$); optical searches for binaries with unseen companions would clearly be a more sensitive method of searching for such objects. Our limits for an isolated black hole or neutron star accreting interstellar material are similarly weak: for spherical accretion[80],

$$L_X = 7\times10^{31}\left(\frac{\zeta}{0.1}\right)\left(\frac{\rho}{1\ \mathrm{cm^{-3}}}\right)\left(\frac{M}{1.4\ M_\theta}\right) \times\left(\frac{v}{10\ \mathrm{km\ s^{-1}}}\right)^{-3}\ \mathrm{erg\ s^{-1}}$$

where v is the object's velocity with respect to the infalling matter. Thus, an isolated 10 $M_\odot$ black hole might be detectable to 5 kpc, but a neutron star (likely to be moving at a considerably higher velocity) would probably not be observed in even the nearest remnants.

Source classes

We have divided the observed compact objects into three groups: accretion-powered binary sources (SS433 and G109.1−1.0), active pulsars as defined by the presence of pulsed radiation and/or a surrounding synchrotron nebula (Crab, Vela X, MSH15−52 3C58, CTB80), and isolated, noninteracting objects (RCW103, G27.4+0.0, PKS1209−51/52, W28, and G127.1+0.5). Within each category, the sources are listed in Table 1 in order of decreasing likelihood that they are true members of their class; amongst the final group, we feel it is rather unlikely that any of the last three objects are actually associated with the surrounding remnant. Although the survey of galactic SNR in X rays (the preferred band for detection) is incomplete, it is unlikely that any significant new data will be obtained in the near future, so it seems appropriate to consider at this time the statistical implications of the current list of objects.

Binary sources: Although some doubts have been expressed that the nebulae surrounding SS433 and G109.1−0.1 are, in fact, remnants of the SN which created the compact objects we see, the central location and low probability of chance occurrence for these sources is highly suggestive of real association. The sources are radically different from each other in many of their observed properties, but both probably consist of a near main-sequence star and an accreting collapsed companion. While their radio and optical luminosities are very different, both are strong X-ray sources which would have been easily detected (a factor of $>10^2$ above threshold) in any of the 63 shell-type galactic SNR surveyed with the Einstein satellite; SS433 was originally detected by Uhuru and a similar source would have been seen by other all sky surveys out to $\geq$10 kpc, a distance encompassing ~100 of the known galactic SNR. Thus, we can conclude that $\leq$3% of SN leave behind systems which, on a time scale less than the lifetime of the expanding remnant ($3–10\times10^4$ yr), become accreting X-ray binaries.

As most stars occur in binary systems, these results hold important implications for binary disruption probabilities in the SN event. In Table 3 we summarize the possible pre- and post-SN configurations of a binary system. The stars are divided into three mass regions: $M > 10M_\odot$ (earlier than B3) for which there is general agreement that the star will end its life as a SN; $4\,M_\odot < M < 10M_\odot$ (B9–B3), a range in which post-main-sequence evolution is particularly uncertain, but within which it is believed that at least some of the stars explode and leave collapsed remnants; and $M < 4\,M_\odot$ (later than A0), for which there is general agreement that most stars evolve to white dwarfs. Table 3 gives the zero-age main sequence mass range of the primary (more massive) and secondary binary components and lists the post-SN configuration for each of two possible scenarios: first, mass conservation, in which most of the material lost by the primary is transferred to the secondary; and second, extensive mass loss, in which the separation of the stars is sufficiently large that only a small fraction of the primary's mass is accreted by its companion. The final column of Table 3 presents the expected observational consequences of the various scenarios. If the SN does not leave behind a collapsed object (a neutron star or black hole), clearly, no accretion-powered source will be seen. If a collapsed object is produced, we have several possibilities:

(1) The companion is a massive star ($>4\,M_\odot$) and, as such, has a stellar wind strong enough to produce an observable X-ray source (cases Ia and b, IIa and b, IIIa, IVa and b, and Va).

(2) The companion has $M < 4M_\odot$ (cases IIIb and Vb). However, in this case, as greater than one-half the mass of the system is lost in the explosion, the system will essentially always disrupt.
(3) The SN is produced by accretion onto a white dwarf of matter lost from the companion through Roche-lobe overflow. If the SN leaves a collapsed companion, a visible accretion-powered source will result from the continuing mass loss of the post-main-sequence companion (case VI).

The binary source in G109.1−1.0 almost certainly consists of a neutron star fed by Roche-lobe overflow from a low mass ($<1\ M_\odot$) companion[81] and thus probably resulted from case VI. We note that this would require a white dwarf SN to leave behind a neutron star remnant, in conflict with some current theories of Type I explosions[82]. The companion of the collapsed object in the SS433 system is uncertain although the weight of the evidence[83] seems to favour a low mass companion, again suggesting a case VI scenario.

The lack of visible high-mass accretion sources in SNR suggests that nearly all such systems must disrupt when the first star undergoes a SN. The rarity of binary pulsars (~1%) supports this conclusion. There are ~25 massive X-ray binary systems in the Galaxy[84] which, just after the first SN, should have been embedded in a SNR. That at most one such system is currently seen in this early phase (lasting $\lesssim 5\times10^4$ yr) yields a crude estimate of the lifetime L of massive binaries: $\frac{1}{25} \geqslant (5\times10^4)/L$, implying $L \geqslant 10^6$ yr, commensurate with the lifetimes of the massive companions powering these wind-driven sources. The rarity of low mass X-ray binaries within SNR shells suggests that disruption in the SN event is similarly likely or, that collapsed objects are rarely formed in such systems (that is, exploding white dwarfs usually leave no remnant).

An interesting similarity between SS433 and G109.1−1.0 is that both show evidence for the ejection of relativistic beams[85,86]. Of the ~100 galactic X-ray binaries not found in SNR, however, only Sco X-1 evidences this phenomenon[87,88] although most sources have not been studied at comparable sensitivity in either the radio or X-ray regimes. If this lack of detectable beamed emission is not simply an observational selection effect, it suggests that the phenomenon is a relatively short-lived (few per cent) phase of an X-ray binary's evolution. Similar beams are thought to emerge from isolated young neutron stars where they give rise to the synchrotron nebulae discussed below.

Pulsar-driven nebulae: The largest group of detected compact objects associated with SNR are those embedded in centrally peaked radio and X-ray synchrotron nebulae. The Crab Nebula with its central pulsar is the prototype of this class and, in this one case, the total energy budget of the surrounding nebula is successfully accounted for by the rotational kinetic energy loss rate of the neutron star. In other cases, this link has yet to be directly established. Only two of the remaining four objects in this class, Vela and MSH15−52, are radio pulsars for which the spin-down energies have been measured and, in the latter case, the nebula has only been detected at X-ray wavelengths. Another feature which distinguishes the Crab Nebula (and 3C58) from the other members of this class is the lack of a shell of radio and X-ray emission from an expanding SN shock front surrounding the synchrotron nebula. Such shells are present in MSH15−52, Vela and CTB80, as well as in two other remnants in which the presence of a young pulsar may be inferred from the existence of a bright radio and/or X-ray synchrotron nebula: G29.7−0.3 (ref. 59) and G326.3−1.8 (ref. 89). Other cases of pure Crab-like remants also exist: G21.5−0.9 (ref. 58), and G74.9+1.2 (ref. 90). No systematic observational differences are apparent between the synchrotron nebulae found in shell-type remnants and those in which a shell is absent. Similarly, the shell components of the composite remnants do not appear strikingly different from most SNR in which only the shell is seen. All this suggests that, at least on time scales of $\sim 3\times10^2$–3×10^4 yr, the two components evolve independently; that is, the presence or absence of an active neutron star (pulsar) has little effect on the SNR created by the expanding SN blast wave, and the presence or absence of a shell does not affect the formation of a synchrotron nebula.

The implications of such a statement are significant. Consider those remnants which exhibit shells. Only ~10% (6 of ~50 well-studied galactic remnants) contain a Crab-like nebula. Because all young radio pulsars studied by Einstein produce such a nebula (Crab[50], Vela[57], MSH15−52 (ref. 45), PSR1055−52 (ref. 77) and PSR0355+54 (ref. 78)) we must conclude that no active radio pulsar exists in the other 90% of SNR. Thus, either only ~10% of SN which make shell-type remnants produce neutron stars, or most neutron stars turn on as pulsars after the shell has dissipated[20,21] (~30,000 yr). The former possibility suggests that the convergence of the SNR production rate and the pulsar birthrate is fortuitous, and holds important implications for SN theory. The alternative view of the late pulsar turn-on yields potential information on the evolution of neutron star magnetic fields and the pulsar radiation mechanism. We note that, for a pulsar birthrate of 1 per 40 yr, a significant fraction (0.4–1.0) of SN must leave a neutron star, arguing in favour of this latter alternative.

If we adopt the premise from our observation of composite remnants that only ~10% of neutron stars turn on as radio pulsars within $\sim 10^4$ yr of their formation, we are left to speculate on the inactive counterparts to the shell-less Crab-like remnants—those SN which leave neither shells nor active pulsars. As there are roughly equal numbers of Crab-like remnants with and without shells, the number of inactive neutron stars with and without shells should also be similar; that is, there should be 10 SN which leave no visible remnants for each shell-less Crab-like remnant produced. We are thus led to the rather startling conclusion that nearly half of the SN in the Galaxy leave no promptly observable remnant. We find support for this conclusion in the fact that derived radio remnant formation rates in the Galaxy (1 per 40 (ref. 91) to 80 (ref. 92) yr) have consistently been a factor of ~2 below the estimates of the galactic SN rate (1 per 20 to 40 yr)[18]. The first recorded extragalactic SN, SN1885 (S Aud) in M31 is noteworthy in this regard; after 100 yr it is still undetectable as a radio source at a limit only a few per cent of Cas A.

Isolated objects: Sources 8 to 12 in Table 1 are the remaining point sources which have been found within SNR boundaries. The evidence for association is simply positional coincidence. We have argued above that sources 10, 11, and 12, located in remnants of large angular size, are most probably chance superpositions of foreground or background objects. The object at the centre of G127.1+0.5 has already been identified as a radio galaxy[61,62] and work is under way to identify optical and/or radio counterparts to the sources in PKS1209−52 (ref. 93) and W28. For the remaining two sources, the probability of chance superposition is small (Table 1, column (5c)) and decreases even further when their precise central location within the remnants is considered. The remnant G27.4+0.0 is very distant, and little information is yet available on the X-ray properties of the point source at its centre (J. Kriss, personal communication). Either nonthermal pulsed emission from a young pulsar or emission from a synchrotron nebula (as in other composite remnants) are viable possibilities; its X-ray luminosity (although highly uncertain because of the large correction for interstellar absorption in such a distant source) is not dissimilar from the Crab pulsed luminosity. Black-body radiation from a neutron star surface is an unlikely explanation as the required temperature is $\geqslant 9\times10^6$ K, far above that of other neutron stars and the predictions of theoretical cooling calculations. For RCW103, Tuohy *et al.*[94] have recently argued that surface black-body radiation from a neutron star is the most likely explanation for the X rays observed from the central point source. The lack of an optical counterpart brighter than $m_v = 22$ virtually rules out an accretion-powered source, although owing to the steep period dependence of pulsar optical luminosities, a nonthermal magnetospheric emission mechanism is not excluded. The derived surface temperature under the assumption of black-body

emission is $\sim 2 \times 10^6$ K, consistent with standard neutron star cooling calculations[95].

Conclusions

A total of nine point sources of radiation have now been established as the compact remnants of recent SN explosions. They represent a variety of the known observational manifestations of neutron stars and black holes: accretion-powered binary sources, isolated radio pulsars with their associated synchrotron nebulae, and surface thermal emission. The statistics of the observed objects along with the equally important stringent upper limits to similar radiation from sources in most known SNR provide important information on the galactic SN rate and the origin and evolution of neutron stars. Future study of these sources will contribute substantially to our knowledge of these exotic endpoints of stellar evolution.

Cloud structure on the dark side of Venus

David A. Allen & John W. Crawford*

Anglo-Australian Observatory, PO Box 296, Epping, New South Wales 2121, Australia

Observations of the dark side of the planet Venus at infrared wavelengths between 1.5 and 2.5 μm have shown it to be anomalously bright in portions of this waveband, and to exhibit structured cloud patterns whose rotation period is longer than that of any other clouds.

WHILE it is known[1-3] that the unilluminated hemisphere of the planet Venus radiates at wavelengths near 10 μm with a temperature of 230–240 K, there are no reports of radiation at wavelengths shorter than 3 μm, where thermal radiation should be very weak. We now, however, report observations showing that the unilluminated hemisphere is anomalously bright in this region of the infrared spectrum. We have been able to estimate the rotation period of the features responsible, but cannot offer a definitive explanation of the phenomenon.

We first discovered detectable dark-side radiation at dichotomy (illuminated phase 0.5) in June 1983 using the 3.9 m Anglo-Australian Telescope and IR photometer–spectrometer in its imaging mode. As the planet entered its crescent phase, the structure was easily studied and the observations described here were made on 24 and 25 July (phase 0.23) and 18–23 September (phase 0.19). These observations cover the unilluminated hemisphere near both local sunrise and local sunset, but there are no obvious differences between the cloud patterns in the two cases (Fig. 1). No digital enhancement of the images has been performed so that the contrast is exactly as observed, although our choice of observing wavelength reduced the intensity of the illuminated portion of the disk relative to that of the dark side. At this wavelength, the range of intensity observed on the dark side is 0.03% to 1.0% of the peak intensity.

Observational procedures

The IR photometer–spectrometer is a versatile Cassegrain instrument, and for these observations we used it in its spectroscopy and imaging modes. The InSb detector (0.25 mm diameter) is cooled to 50 K and radiation enters via one of a selection of apertures in the focal plane of the telescope, a filter and a doublet Fabry lens of ZnSe. Samples of the incident data flux are taken over an integration time which may be any integral number of milliseconds from 1 to 10,000.

The filter wheel for the spectroscopic observations contains a circular variable filter with a transmission wavelength which is a function of rotational position. For focal plane apertures less than 3.5 arc s, the bandpass is 0.010 of the wavelength. The spectrum reproduced in Fig. 2 was taken in three portions, corresponding to the three wavebands of atmospheric transmission. In each waveband, the filter was stepped at the end of each integration time, typically 5 seconds being required for a single sweep through the spectrum. The telescope was then driven to a nearby patch of sky (for an account of the d.c. drive electronics, see ref. 4), the spectral sweep repeated and the sky spectrum subtracted from that on the planet. (Since the observations were made at night the sky signal at wavelengths below 2.5 μm was negligible.) The procedure continued for a few minutes in order to derive high signal-to-noise in the faintest portions. The spectra and telluric absorption features were calibrated by observations of a nearby G dwarf star for which accurate photometry is available. The absolute calibration is reliable to 10%, and the detailed shape of the resulting spectrum to significantly greater precision.

When used in imaging mode, the filter remains fixed at a chosen wavelength, the telescope is stepped in a raster pattern in synchrony with the integrations as it moves southwards. Data collection is suspended on its return journey, and irregularities of the telescope's motion at the northern turnaround slightly distort the extreme top of the image, seen here as upward streaking of the northern cusp, an effect enhanced by the high degree of saturation in the illuminated crescent. Successful use of this technique on other planets has been demonstrated[5].

Each image of Venus required about 3.5 min, and usually six consecutive images were combined to produce the final versions, in which irregularities due to seeing are smoothed out. The features of each final image could always be seen on each of its components. All the images were made in daylight, hence the choice of 2.41 μm to maximize contrast against the sky, but images made on 25 July at 1.7 μm and with a broad bandpass of 2.0–2.4 μm were indistinguishable.

The initial pixel size was 1.0 arc s and the focal plane aperture was 2.0 arc s in diameter. Using UK Science and Engineering Research Council's Starlink software, the images were linearly interpolated to 0.5 arc s pixels, and after coaddition, very light gaussian smoothing was applied. The effective resolution was 2.0–2.5 arc s unless poor seeing interfered.

Spectrum of the radiation

Two issues are raised by this discovery. What is the nature of the radiation seen on the dark side? And what causes the intensity modulation?

Figure 2 shows the spectrum of part of the dark side of Venus between 1.5 and 2.5 μm. The spectrum is contaminated to an extent which cannot be accurately determined by radiation from the sunlit portion scattered along the diffraction spikes of the telescope, but in the portions of Fig. 2 where data are shown as a broken line, we believe the signal arises entirely from this cause because of the exact spectral similarity and the credible value of the intensity. An image made at 2.06 μm, in the absorption band of CO_2, shows no structure on the dark side except a gradual fall-off from the sunlit portion. We therefore believe that the dark side radiation is detectable only in the ranges 1.69 to 1.77 μm and 2.18 to 2.50 μm.

We offer the following explanation of the spectral distribution. In the range 2.3–2.4 μm, the prominent double absorption feature is unmistakably that of the first overtone band of CO, at a mixing ratio of 45 p.p.m. convincingly shown to be present by Connes *et al.*[6] who required 600 times greater resolution than ours but who observed the sunlit side of Venus. It is clear that we are viewing radiation that has traversed a much greater path length through the atmosphere, in which circumstances we expect bands of CO_2, the most abundant gas, to be highly saturated. In her important study of the atmosphere of Venus, Young[7] listed all CO_2 bands seen in the data of Connes *et al.* When each one of these is completely opaque, radiation would escape only in the precise wavebands we see, but the peak at 1.74 μm must be further reduced by HCl bands[8]. Apart from very slight changes in the CO band strengths, we find the spectrum of the dark side to be the same in regions differing by a factor of three in intensity.

* Present address: Department of Astronomy, Glasgow University, Glasgow G12 8QQ, UK.

0028-0836/84/030222—03$01.00

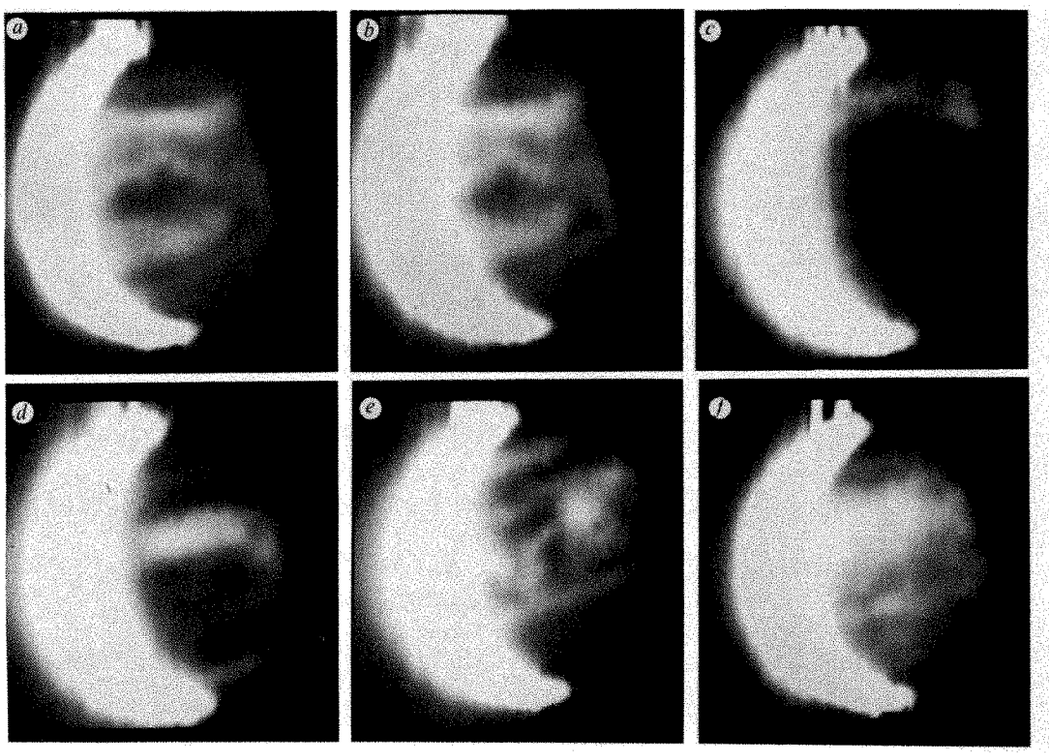

Fig. 1 Images of Venus at a wavelength of 2.41 μm made on several dates in September 1983. The bandpass was 0.025 μm and the spatial resolution better than 2.5 arc s. North is at top and east to the left on all images. Dates and UT times are September 1983 at 1720:54 (*a*), 1723:22 (*b*), 1921:30 (*c*), 2101:13 (*d*), 2120:53 (*e*), and 2220:16 (*f*). Several dark spots in image *b* were caused by electronic faults affecting the raw data.

Using the convenient data of Kuiper[9] we estimate the column absorption of CO to be equivalent to a 10-m path at atmospheric pressure. When allowance is made for the abundance of CO relative to the other components of the atmosphere of Venus, the observed path must be of the order of 200 km atm. This large value may arise in either a vertical or a dominantly horizontal path. The brightness temperature in the peak of the 1.74 μm region is 450 K, a value found only near the base of the major cloud decks[10], which would be consistent with a vertical path of 200 km atm provided that the absorption optical thickness of the clouds permits the passage of radiation. The clouds are known to have very large scattering optical thicknesses at all optical and infrared wavelengths[11–13].

The only other continuum source available is sunlight, which would have to be scattered from the illuminated hemisphere by the upper cloud layers. Since our images show little indication of a fall in brightness away from the terminator, the scattering could not be accompanied by significant absorption. We note that if such a mechanism were operative at visible wavelengths, the unilluminated side of Venus would be far from dark.

Nature of the clouds

The nature of the cloud structure is far from clear. Superficially, the patterns seen in the IR on the unilluminated hemisphere resemble those seen at UV wavelengths on the sunlit side[14]. From observations on successive days during one complete rotation we derive a retrograde rotation period of 5.4 ± 0.1 days based largely on the return of the leading edge of a very extensive dark area seen near the limb. The error does not take account of the considerable changes in the structure of the clouds during one revolution of the planet (compare Fig. 1*a* and *f*). Estimates of the rotation period based on the observing period of less than six hours possible each day range from 5 to 7 days. The rotation period is distinct from that of the UV cloud patterns (3.94 days, though with some suggestion of longer periods)[15], and the infrared dipolar feature (3.0 days)[16], but it is similar to that of low-contrast features at 11–15 μm (5.3 days)[17]. The pole of the rotation is poorly determined from these data.

The origin of the UV clouds is still not definitely known, but it seems most likely that SO_2 and elemental sulphur, lying in a high-altitude haze, absorb sunlight reflected off the uppermost cloud deck[18–20]. Moreover, the same cloud deck reflects sunlight between 1 and 4 μm (ref. 21). But since we see no prominent

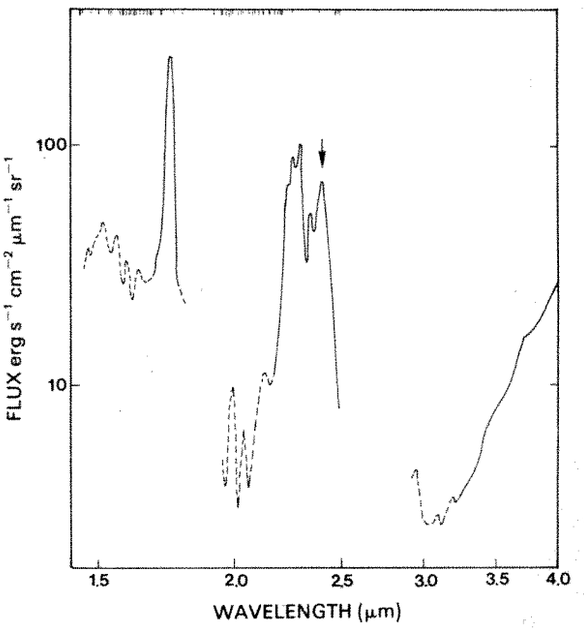

Fig. 2 Spectrum of a small portion of the dark side of Venus, taken on 25 July 1983. Where shown as a broken line the data are dominated by radiation from the sunlit crescent scattered into the beam by the telescopic optics. Beyond 3.3 μm thermal radiation at a brightness temperature of 220 K is seen. Ticks on the upper margin indicate the locations of CO_2 absorption bands. The arrow indicates the observing wavelength for the images in Fig. 1.

cloud structure on the sunlit side at our observing wavelengths, it cannot be the UV absorber that causes the dark-side structure. This conclusion is further strengthened by the fact that neither SO_2 nor elemental sulphur exhibits known absorption in the wavebands of our data except at high overtones.

Markings at very low contrast resembling the UV features, and hence similar to those we now report, have been suspected on the sunlit side at longer IR wavelengths[22,23]. These are of much lower contrast than the patterns we find on the dark side. Hence we infer that the clouds responsible for the dark-side modulation lie below (or perhaps within) the uppermost cloud

layer. They must therefore have an origin distinct from that of the UV features, but a direct correlation would, nonetheless, be of considerable interest.

Trace element patterns at a non-marine Cretaceous–Tertiary boundary

J. S. Gilmore*, J. D. Knight*, C. J. Orth*, C. L. Pillmore† & R. H. Tschudy†

* Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA
† US Geological Survey, Denver, Colorado 80225, USA

At the fossil-pollen-defined Cretaceous–Tertiary boundary in the Raton Basin of New Mexico and Colorado, an iridium abundance anomaly and excess scandium, titanium, and chromium are associated with a thin ash or dust fallout bed (now kaolinitic clay) that was preserved in freshwater coal swamps.

THE Ir abundance anomaly occurring in a thin zone at the planktonic Cretaceous–Tertiary (K–T) boundary in marine sediments, which was discovered by Alvarez *et al.*[1,2] and hypothesized by them to be due to fallout from impact of a large extraterrestrial body, has now been reported at numerous sites around the world[1–11]. Both the evidence and the concept have been challenged, and some opponents have argued that the excess Ir in these sediments can be explained by normal chemical and physical processes in the ocean[12–17].

The possibility of another approach to this problem lay in a search for the anomaly in continental sediments deposited in freshwater conditions. In early 1981 we located an Ir anomaly in a core collected in York Canyon, in the central part of the Raton Basin of northeastern New Mexico and southeastern Colorado[18,19]. The peak Ir concentrations, reaching 5.6×10^{-9} g per g (5.6 ng per g) over a background of 0.004 to 0.020 ng per g, occurred at the base of a thin coal bed within 1 cm of the pollen-defined K–T boundary. Samples taken from above and below the K–T boundary, including the bases of similar coal beds, showed no evidence of Ir enrichment.

Success in locating an Ir anomaly in the York Canyon core led us to search in outcrops and roadcut exposures along the eastern margin of the Raton Basin. Detailed examination of samples from four of six additional Ir anomaly sites that were located, in addition to the original York Canyon core, has provided us with data regarding the distribution of elemental abundance patterns across the boundary zone, as well as the lithology of the zone. We now report elemental abundance patterns across the K–T boundary over a large area with a common palaeoenvironmental setting in the Raton Basin. We include some supplementary observations made recently on another non-marine K–T boundary, near Jordan, Montana (1,200 km north of the Raton Basin). Interpretation of the data provides clues about the source of the excess Ir and the thin kaolinitic clay bed associated with it.

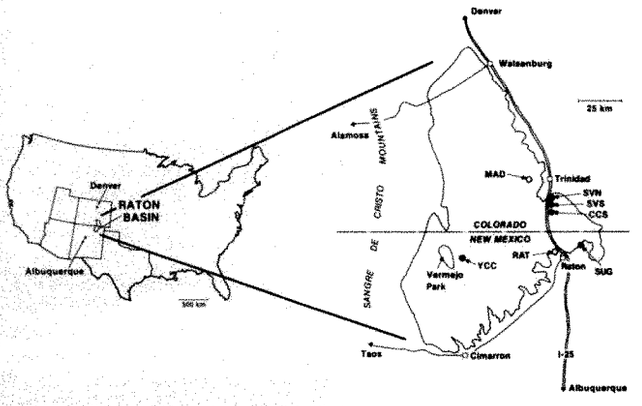

Fig. 1 Outline of present-day Raton Basin and its location in Colorado, New Mexico, and the continental United States. ●, Sites discussed in this work: YCC, York Canyon core; SUG, Sugarite; SVN, Starkville-north; SVS, Starkville-south; CCS, Clear Creek-south. ○, Ir anomaly sites not discussed in this work: MAD, Madrid; RAT, Raton.

Measurements

The five Ir anomaly sites for which elemental abundances are reported are shown in Fig. 1 (also shown are two additional sites, Raton (RAT) and Madrid (MAD), at which the Ir anomaly has been found, but for which sampling was not completed). At the outcrop or roadcut locations, after preliminary sampling and palynological examination to establish the K–T boundary, we collected a continuous sequence of samples across the boundary zone at intervals of 0.5–6 cm and at selected levels both above and below the zone (vertebrate fossils have not been reported here); 10–40 cm of surface material were discarded before sampling. Although some of the results for the York Canyon core have been reported previously[18,19], these and new data are included because they provide a comparison of elemental distributions observed in an unweathered environment (core) with those observed in the more weathered near-surface conditions at the outcrop and roadcut locations.

All of the abundances except for nickel were determined by instrumental neutron activation analysis. Two portions (3–5 g) from each sample were irradiated with thermal neutrons. One portion was placed in an automated system that provides abundances for about 24 elements[20]. The second portion was irradiated

0028–0836/84/030224—05$01.00

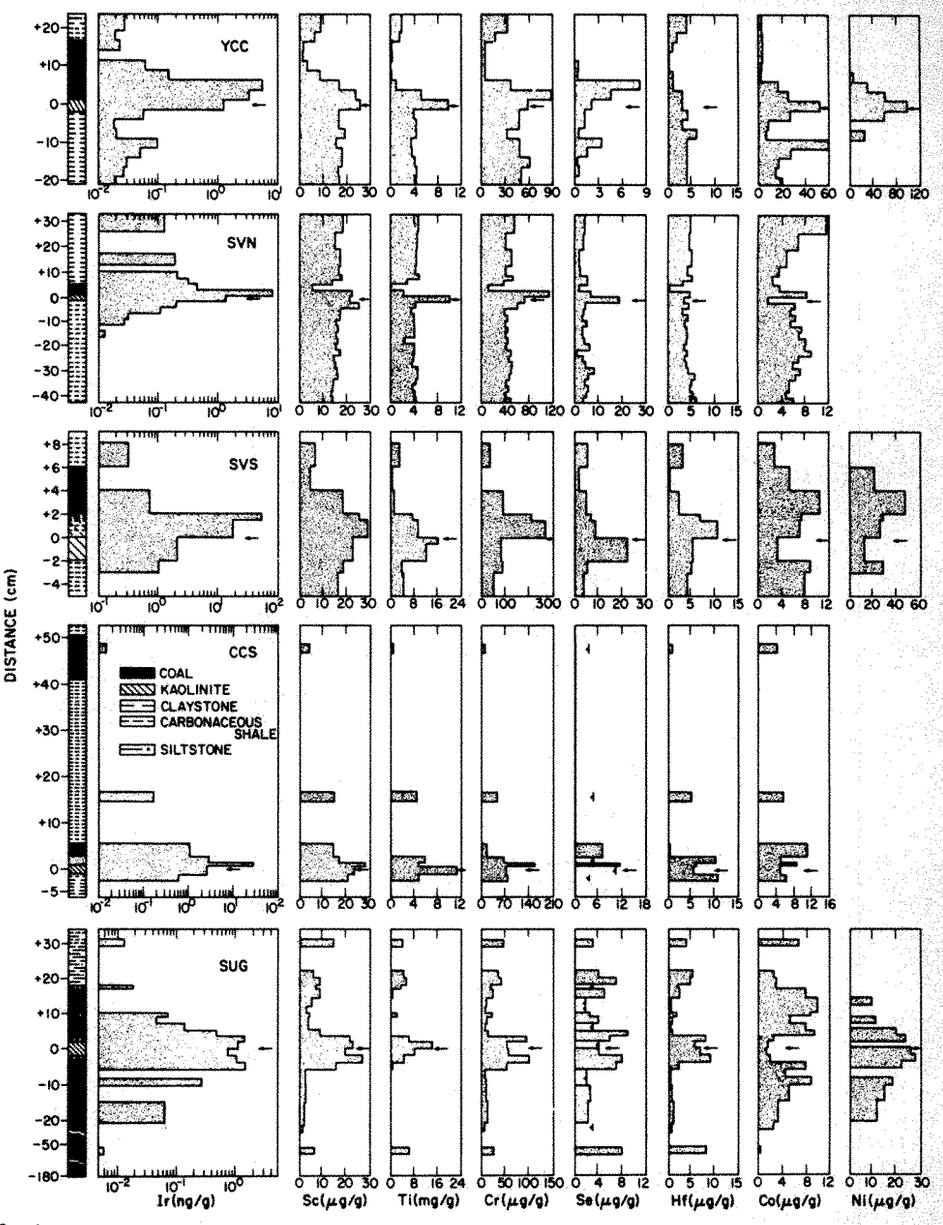

Fig. 2 Elemental abundance diagrams for the sites shown with solid circles in Fig. 1. Note that the Ir abundances are plotted on logarithmic scales. The distances up (+) and down (−) section are referenced to the centre of the K–T kaolinitic clay bed (0); arrows indicate this reference level. Vertical bars with left-pointing arrowheads (Se) represent upper limits. Ni was not measured at the SVN and CCS sites.

for 24 h with 1.4×10^{12} neutrons cm^{-2} s^{-1} in order to build up the radioactivity level of long-lived species such as 74-day ^{192}Ir. For determination of Au/Ir and Pt/Ir ratios a 1-g portion was irradiated for 7 h with 5.7×10^{12} neutrons cm^{-2} s^{-1} and radiochemical separations were performed.

Concentrations of nickel, whose nuclear properties are not well suited for thermal neutron activation techniques, were determined in a few selected samples using a plasma emission spectrometer.

Results

Elemental abundance data for the five sections discussed here are plotted in Fig. 2. At each of these five sites we have found only one Ir anomaly, at the base of the thin coal bed containing the K–T boundary as defined by fossil-pollen changes. This pattern of observations supports the inference that quiet swamp conditions were crucial for the sheltering of Ir-bearing material against dilution by mixing processes. In several closely spaced sections at a site near the city of Raton, the Ir anomaly is rather weak (1 ng per g), and the kaolinite-rich parting, while overlain by a thin coal bed, seems to be contaminated with detrital clay.

In the Raton Basin the palynological K–T boundary interval occurs in a rock sequence deposited in freshwater swamps and flood plains[18,19,21]. These rocks lie in the lower part of the Raton Formation, of late Cretaceous and Palaeocene age.

At York Canyon, the surface density (total deposition per unit area) of the Ir anomaly shown in Fig. 2 is about 40 ng cm^{-2}. The kaolinite-rich bed at the base of the coal is not visibly distinct from the underlying mudstone, owing to darkening from carbonaceous material; the presence of the kaolinitic clay was determined by X-ray analysis and, once its elemental abundance pattern was established from the elemental systematics of the other K–T kaolinite-rich beds in the basin, by that pattern.

At the Starkville–North Section (SVN), in a roadcut south of Trinidad, Colorado, the kaolinitic bed at the K–T boundary is clearly recognizable, because it has weathered to a grey colour and is located between coal and dark brown carbonaceous shale. The Ir surface density is about 50 ng cm^{-2}, and the Ir concentration reaches a maximum of 8 ng per g.

The Starkville–South Section (SVS) was taken from a roadcut about 500 m south of SVN. Here the Ir concentration reaches 56 ng per g, the highest we have observed in the basin, in a thin (5 mm) shaley bed between the base of the coal and the kaolinitic-clay layer. The Ir surface density here is ~120 ng cm^{-2}.

The Clear Creek–South Section (CCS) was taken about 2 km south of SVS. The Ir concentration shown in Fig. 2 reaches a maximum level of 28 ng per g in a thin (2 mm) carbonaceous–kaolinitic shale that lies on the kaolinitic clay stone bed, and the surface density is ~50 ng cm^{-2}.

† See text for discussion of this analysis.

The section from the Sugarite site (SUG), located 10 km east of Raton, includes a 2-m-thick coal bed. The Ir surface density is about 32 ng cm^{-2}. This section is of particular interest because the Ir-enriched zone is sandwiched between two layers of coal and appears to be relatively uncontaminated by detrital clay. Figure 2 shows that the Ir concentration reaches its maximum (1.5 ng per g) not in the thin kaolinitic layer, but in the adjacent coal just above and below. A similar displacement is seen at the other four sampling sites: the Ir concentration reaches its maximum in the coal slightly above the clay layer. This distribution is consistent with spreading due to a combination of at least two dispersion mechanisms: (1) mixing with plant matter following deposition of Ir-bearing fallout; and (2) chemical migration in the acid environment associated with the transformation of plant matter to coal. Iridium concentrations in 27 other non-K–T coal beds and 21 other kaolinitic beds examined in the Raton Basin are <0.040 ng per g.

The abundance for each element in the SUG K–T kaolinitic clay bed alone was estimated by integrating its net surface density (coal bed background subtracted from the total measured) over individual sample widths and dividing by the surface density of the clay layer (8.8 g cm^{-2}). These abundances are compared in Table 1 with crustal averages and with lunar soil and basalt, chondrites and achondrites. Figure 2 indicates that at the SUG site boundary, Sc, Ti, Cr, Hf and Ni are enhanced in this layer relative to their values in the strata above and below.

Of the elemental abundances measured, four show strong positive correlation with Ir: Sc, Ti, Cr and Pt. Analysis of all data taken in the K–T kaolinitic clay zone shows the following correlation coefficients: Sc/Ir = 0.93, Ti/Ir = 0.95, Cr/Ir = 0.96, Pt/Ir = 0.98. Two other siderophile elements measured, Co and Ni, exhibit no significant correlation with Ir at any of the outcrop sampling sites. Only in the York Canyon core can a clear positive correlation with Ir be observed for these two elements. All of the anomaly sites in the Raton Basin apparently had a common genesis, and thus we suspect that the lack of correlation for Co and Ni with Ir in the outcrop and roadcut sites is associated with their exposure to oxidizing and leaching conditions.

We have measured Pt and Au in eight samples from the York Canyon core and also some from three of the roadcut sites. In all samples measured the Pt correlated very closely with the Ir, but the Au did not. The concentration of Au peaks near the Ir spike but does not drop to very low levels on either side. Instead the Au background concentration remains at several ng per g throughout the sampled sections.

In Table 2 Pt/Ir and Au/Ir data for the peak Ir samples at four Raton Basin sites are compared with corresponding data for the Stevns Klint, Denmark, and Caravaca, Spain, K–T boundary clay, terrestrial volcanic rocks, lunar soil, and Cl chondrites. Unfortunately, there is a paucity of Pt/Ir data for terrestrial basalts, due probably to the difficulty of measuring Pt at very low concentrations. The Au/Ir ratios for the Raton Basin are higher than observed in the marine K–T sites; however, they are distinctly lower than the Au/Ir ratios reported for terrestrial basalts. Finally, we see that the Pt/Ir ratios at our measured Ir spikes fall around the value for Cl chondrites.

In every Raton Basin sampling site where an Ir anomaly has been found, the anomaly and the pollen break are associated with a 2- to 4-cm kaolinite-rich clay layer overlain by coal. We have performed elemental analyses on this K–T kaolinite-rich clay bed at six sites, and on 21 other thin kaolinitic clay layers found in other coal beds from about 50 m below to about 300 m above the one containing the K–T boundary. The data are summarized in Table 3. The eight trace elements from Sc to Sb, as well as Ir, are higher in the K–T boundary kaolinitic clay bed than in the others. Although thin kaolinitic clay layers of this kind (commonly referred to as tonsteins) are identified as the alteration product of volcanic ash falls[22,23], the distinctively different trace-element character of the K–T layer suggests a different origin.

A similar pattern emerges from results obtained at another group of freshwater K–T boundary exposures, 1,200 km to the north, near Jordan, Montana. From this area, in which the K–T Ir anomaly was first reported by Alvarez[24], we have examined samples collected by Bohor and Triplehorn from Brownie Butte, in the vicinity of Hell Creek, where Tschudy[25] established the palynological K–T boundary at the lowest lignite bed of the Tullock Member of the Fort Union Formation. Here the Ir anomaly is associated with a 0.5- to 1.5-cm kaolinitic clay bed overlain by several centimetres of lignite. Although the Brownie

Butte location was in a different floral province during the Cretaceous, the fossil pollen taxon *Proteacidites* occurred in this area and in the Raton Basin. At both locations we have found that this late Cretaceous marker pollen disappears at the top of the clay layer containing the Ir anomaly.

The higher abundance of Ti in the K–T kaolinite-rich clay bed is of some interest. Apart from considerations of its origin, this distinctively higher concentration provides a useful marker for preliminary identification of the boundary bed. In the neutron activation analysis procedure, Ti abundances are determined within minutes, whereas the Ir measurements require long-term irradiation followed by lengthy radiochemical analysis, and thus a high Ti value offers an early alert.

In previous discussions of the Ir enrichment phenomenon, consideration has been given to the possibility that the anomalous material at the K–T boundary may have arisen from volcanism[13,16,17]. The period from the late Cretaceous through the early Tertiary was marked by a high level of volcanic activity in the western interior of North America[26], which could have led to a kaolinitic clay layer of the kind found at the Raton Basin K–T boundary. We have attempted to gain some information on the plausibility of this source by comparing the elemental abundances of the K–T kaolinitic clay bed with those of similar beds above and below it (Table 3), and with those of various other volcanic rocks (Table 4). Table 3 shows that Sc, Ti, Cr and Ir are distinctly more abundant in the K–T bed. The light to heavy rare earth ratios, La/Yb, on the other hand, are about the same and in a range characteristic of crustal rock. The

enhanced concentrations of Sc, Ti and Cr in the Raton boundary clay suggest that this bed may represent the alteration product of basalt or the ash from a basic volcano. Spears and Kanaris-Sotiriou[23] have reported that in British and other European Carboniferous-age tonsteins, the ratios TiO_2/Al_2O_3 and Cr/Al_2O_3 remain virtually unchanged as the volcanic ash alters, and basic ash gives high values for these ratios whereas acid ash gives low values. They point out that basic ratios can be lowered by the addition of sedimentary material. On the basis of TiO_2/Al_2O_3 ratios in Table 3, the K–T kaolinitic layer would have to be ascribed to a basic volcano, whereas all the other beds would have to be ascribed to acid volcanoes.

Of the mafic volcanic and plutonic rocks listed in Table 4, only the dunite and the ultramafic nodule contain Ir in concentrations comparable with those found in the K–T clay layer. However, their Cr concentrations are an order of magnitude too high. Thus, we have difficulty constructing a volcanic source

that yields the elemental abundance patterns we observe in the Raton Basin K–T boundary bed. Also, basic volcanoes are usually less explosive than their acidic counterparts.

The enrichment of Sc, Ti, Cr and Pt-group elements in the K–T kaolinite also suggests a similarity with lunar surface material. Ruderman and Truran[27] have proposed that the K–T fallout resulted from capture by the Earth of lunar surface material ejected by intense photon heating from a nearby supernova burst. The plausibility of this scenario, however, is contradicted by the rare earth measurements shown in Tables 1 and 3. The observed light/heavy rare earth ratios (La/Yb) for our boundary zone samples lie in the range 8–57, characteristic of the Earth's crust. Reported lunar rocks range from 0.9 to about 3, clearly distinct from the former.

Conclusions
